Camera Image Signal Processor

This chapter describes the camera image signal processor (ISP2P) in the device. ISP2P is backward compatible with ISP2 that is in the legacy device. To facilitate reading in this chapter, ISP2P will be referred to as ISP.

NOTE: Some of the information in this chapter is © 2005-2008 MIPI Alliance, Inc. All rights reserved.

MIPI Alliance Member Confidential.

All rights reserved. This material is reprinted with the permission of the MIPI Alliance, Inc. No part(s) of this document may be disclosed, reproduced or used for any purpose other than as needed to support the use of the products of TI.

See [Device 37xx MIPI Disclaimer](#) for details.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5](#), *AM/DM37x Family*, and the device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

6.1 Camera ISP Overview

The camera ISP is a key component for imaging and video applications such as video preview, video record, and still-image capture with or without digital zooming.

The camera ISP provides the system interface and the processing capability to connect RAW image-sensor modules to the device.

The camera ISP implements three receivers which are named CSI2A, CSI1/CCP2B, and CSI2C. The CSI2A and CSI2C are MIPI® D-PHY CSI2 compatible. The CCP2B (compact camera port) is MIPI D-PHY CSI1 compatible if used in CSI1 mode. Moreover, on the outside boundaries of camera ISP before the mentioned above receivers, are located two MIPI D-PHY CSI2 compliant physical layers (CSIPHY1 and CSIPHY2). The two PHYs are MIPI CSI2 and MIPI CSI1/SMIA CCP2 compliant. Their purpose is to act as a physical connection between the outside pins for connecting external sensors and the internal receivers. By configuring the outside PHYs and feeding the receivers, the camera ISP supports up to two simultaneous pixel flows from external sensors. Only one of the data flow can use the Video processing hardware while the other must go to memory.

[Figure 6-1](#) shows the camera ISP overview diagram.

Figure 6-1. Camera ISP Overview Diagram

- (1) The mode for each PHY can be selected from CSI2, CSI1/CCP2B, and GPI at SCM.CONTROL_CAMERA_PHY_CTRL register. It can also control the connection between one of the PHY's and CSI1/CCP2B receiver via multiplexing.
- (2) There is no top-level muxmode (padconf SCM register) control bit for the different camera modes supported by the interfaces. If one or another of the interfaces is enabled, then the camera input signals will be automatically routed to the corresponding ISP receiver depending on the PHY operating mode settings (SCM.CONTROL_CAMERA_PHY_CTRL register).

NOTE: For information about initializing and configuring the CSIPHY, see [Section 6.5.2, Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY](#).

6.1.1 Camera ISP Features

The camera ISP can support the following features:

- **Image sensor:**
 - Interface with various image sensors:
 - R, G, B primary colors
 - Ye, Cy, Mg, G complementary colors
 - Support for electronic rolling shutter (ERS) and global-release reset shutters
- **CSI1/CCP2B serial interface:** The CSI1/CCP2B receiver is compatible with the SMIA CCP2 specification and the MIPI CSI1 specification. It supports the following features:
 - Image from sensor
 - Transfer of pixels and data received by the associated PHY to system memory or to the Video processing hardware
 - Unidirectional data link
 - 1D and 2D addressing mode
 - Maximum data rate of up to 650 Mbps in CCP2 mode and 208 Mbps in CSI1 mode
 - False synchronization code protection
 - Ping-pong mechanism for double-buffering
 - Support of RGB, RAW, YUV, and JPEG formats
 - DPCM decompression supported
 - Image read from memory
 - RAW formats supported
- **Two MIPI CSI2 serial interfaces:** The camera ISP implements two MIPI CSI2 serial interface receivers (CSI2A and CSI2C). The CSI2 receivers enables data transfer at up to 2Gbps. It is based on the MIPI CSI2 Specification 1.0.
 - Transfer pixels and data received by the CSIPHY1 or CSIPHY2 to the system memory or to the Video processing hardware
 - Uses unidirectional data link
 - Supports up to two data-configurable links, in addition to the clock signaling
 - Maximum data rate of up to 1000M bps per data lane
 - Data merger configuration for CSI2A two data lanes and CSI2C one data lane
 - Error detection and correction by the protocol engine
 - DMA engine integrated with dedicated FIFO
 - Streaming 1-D and 2-D addressing mode (rotation is not supported by the 2D mode)
 - Ping-pong mechanism for double buffering
 - Burst support
 - RAW frame transcoding. Including DPCM and A-law compression
 - JPEG support for unknown length transfer
 - RGB, RAW, and YUV formats supported
 - Storage in progressive mode for interlaced stream (using line numbering)
 - Conversion of the RGB formats
 - Configuration of the associated PHY through Serial Configuration Port (SCP)
 - Fully configurable interface of PHY: position of the clock and data and order of +/- differential signals for each pair.
 - Low power mode using PRCM protocols
- **Parallel interface:** The camera parallel interface (CPI) supports two modes:
 - **SYNC mode:** In this mode, the image-sensor module provides horizontal and vertical synchronization signals to the parallel interface, along with the pixel clock. This mode works with 8-,

10-, 11-, and 12-bit data (if using CCDC inside the Video processing hardware above 10 bit data must be internally converted to 10 bit by the Bridge lane shifter). SYNC mode supports progressive and interlaced image-sensor modules.

- **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. The horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds start-of-active video (SAV) and end-of-active video (EAV) synchronization code. This mode works in 8- and 10-bit configurations.
- **Video processing hardware:** The Video processing hardware removes the need for expensive camera modules to perform processing functions. It consists of parts: front end and back end:
 - **Video processing front end (VPFE):** Performs signal-processing operations on RAW image input data. The output data can go directly to memory for software processing, or to the video-processing back end for further processing. The Video processing front end is supported by the CCDC module. Signal-processing operations include:
 - Optical clamping
 - Black-level compensation
 - Look-up table (LUT) based faulty pixel correction
 - 2D lens-shading compensation
 - Data formatter
 - Output formatter

NOTE: Up to 12-bit data at 83 MHz can be transferred from the video port to the ISP submodules. The video processing ISP can treat one pixel every two interconnect clock cycles.

- **Video processing back end (VPBE):** Performs signal-processing operations on RAW image input data. Outputs YCbCr 4:2:2 data.
 - **Preview module:** Signal-processing operations include:
 - A-law decompression: transforms non-linear 8-bit data to 10-bit linear data. The CCDC module can perform A-law compression
 - Noise reduction and faulty pixel correction
 - Dark frame capture and subtraction
 - Horizontal median filter
 - Programmable filter: 3x3 kernel of the same color
 - Couplet faulty pixel correction
 - Digital gain
 - White balance
 - Programmable color filter array (CFA) interpolation: 5x5 kernel
 - Black adjustment
 - Programmable color correction (RGB to RGB)
 - Programmable gamma correction: 1024 entries for each color
 - Programmable color conversion (RGB to YCbCr 4:4:4)
 - Color subsampling (YCbCr 4:4:4 to YCbCr 4:2:2)
 - Luminance enhancement (non-linear), chrominance suppression and offset
 The preview module can also work from memory to memory.
 - **Resizer module:** Performs on-the-fly upsampling (up to x4) and downsampling (down to x0.25) of YCbCr 4:2:2 data by applying high-quality horizontal and vertical filters. The horizontal and vertical resizer ratios are independent. Applicable ratios are 256/N, with N ranging from 64 to 1024. This feature enables digital zooming (upsampling) and video preview (downsampling).
The resizer module can also work from memory to memory. Higher or lower ratios can be obtained by combining on-the-fly resizing followed by memory-to-memory resizing.

- **Statistic collection modules (SCM):** The host CPU uses statistics to adjust various parameters for processing image data.
 - **3A metrics:** Collects on-the-fly RAW image data metrics, which are required to perform the control loops for auto white balance (AWB), auto exposure (AE), and autofocus (AF). The MPU subsystem typically uses data metrics to adjust various parameters for processing image data.
 - **Histogram:** Performs on-the-fly pixel binning of RAW image, based on color value ranges and regions. Supports up to 4 regions and up to 256 bins per color. The MPU subsystem typically uses the histogram with 3A metrics to adjust various parameters for processing image data.

The histogram module can also work from memory to memory.
- **Central-resource shared buffer logic (SBL):** Buffers and schedules memory accesses requested by camera ISP modules
- **Circular buffer:** Prevents storage of full image frames in memory when data must be postprocessed and/or preprocessed by software
- **Memory management unit (MMU):** Manages virtual-to-physical address translation for external addresses and solves the memory-fragmentation issue. Enables the camera driver to dynamically allocate and deallocate memory; the MMU handles memory fragmentation.
- **Clock generator:** Generates two independent clocks that can be used by two external image sensors
- **Timing control:**
 - Generation clocks passed to the clock generator
 - Generation of signals for strobe flash, mechanical shutter, and global reset. Support for red-eye removal.
- **Open core protocol (OCP) compliant:**
 - One 64-bit master interface connected to L3
 - One 32-bit slave interface connected to L4

6.2 Camera ISP Environment

6.2.1 Camera ISP Functions

Table 6-1 describes the camera ISP functions and the corresponding application fields.

Table 6-1. Camera ISP Functions

Function	Description
Parallel interface in generic configuration (SYNC mode)	The camera ISP supports up to 12 bits (If CCDC used inside the Video processing hardware, data must be converted to 10 bit by the Bridge lane shifter). The camera ISP can interface with RAW interlaced or progressive image sensors using RGB or complementary color mosaic filters.
Parallel interface in ITU-R BT.656 configuration (ITU mode)	The camera ISP can extract the synchronization signal start of active video and end of active video from the ITU-R BT.656 bit stream. 8-bit and 10-bit modes are supported.
CSI1 / CCP2B serial interface configuration (serial mode)	The camera ISP supports one CCP2B serial interface, compatible MIPI CSI1.
MIPI CSI2 serial interfaces (CSI2A and CSI2C) configuration (serial mode)	The camera ISP supports two MIPI CSI2 serial interface.

NOTE: The two CSI2A and CSI2C receivers and the CSI1/CCP2B receiver can be active simultaneously. Either the CSIPHY1 or CSIPHY2 data can go through the selected interfaces to the video-processing hardware, while the other data are sent directly to memory by the receiver selected.

The parallel interface is limited to 10 bits when used simultaneously with the CSI2A or CSI2C receivers.

The parallel interface cannot be used simultaneously with the CSI1/CCP2B receiver.

6.2.3 Camera ISP Connectivity Schemes

The cam_d[9:6] implements the CSIPHY1. The cam_d[1:0] implements the CSIPHY2. Moreover, the PHY's can be configured in GPI, CCP, or D-PHY modes from the control module and the SCM.CONTROL_CAMERA_PHY_CTRL control module register. Besides the mode set, from the SCM.CONTROL_CAMERA_PHY_CTRL[4] CSI1_RX_sel sets which PHY will be hooked to the CSI1/ CCP2B receiver of the ISP. Some initialization and pad configuration must also be done. For information about initializing and configuring the CSIPHY, see [Section 6.5.2, Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY](#).

- In GPI mode, the PHY can be connected to a parallel camera (CAM_D[1:0] in CSIPHY1 and CAM_D[9:6] in CSIPHY2)
- In CCP mode, the PHY can be connected to a CCPV2 camera (strobe/data pairs) or a CSI1 camera (clock/data pairs)
- In D-PHY mode, the PHY can be connected to a CSI2 camera (2 or 1 data lane in CSIPHY1 and 1 data lane only in CSIPHY2)

Table 6-3. Camera ISP Connectivity Schemes

(8) Limited: Some data/clock lines connected

NOTE:

- If the parallel camera sensor is the only sensor connected to one CSIPHY, the SCM.CONTROL_CAMERA0_PHY_CAMMOD and SCM.CONTROL_CAMERA1_PHY_CAMMOD bits must be set to 0x11 (that is, GPI mode).
- If the parallel camera sensor and the other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the CONTROL_CAMERAx_PHY_CAMMOD bit must be set for CCP2 or CSI2 mode, respectively, (even if only one pair is used as GPI for CPI mode). In that case, the corresponding [CSI2_COMPLEXIO_CFG1.DATAx_POSITION](#) bit must be set to 0x0 for the lane used in GPI mode.

6.2.4 Camera ISP Protocols and Data Formats

6.2.4.1 Camera ISP Parallel Generic Configuration Protocol and Data Format (8, 10, 11, 12 Bits)

The SYNC mode implements a generic parallel interface with the image sensor. The SYNC mode supports 8 to 12-bit-wide data signals.

In this configuration, no assumptions are made on the data format of pixels, but the dynamic range is limited to 8-, 10-, 12 bit (data can be pure luminance for black and white sensor, RGB444, Bayer RGB, etc.). The pixel data is presented on `cam_d`, where one pixel is sampled for every `cam_pclk` rising edge (or falling edge, depending on the configuration of `cam_pclk` polarity). For more information, see [Section 6.4](#).

Additional pixel times between rows represent blanking periods. Active pixels are identified by a combination of two additional timing signals: horizontal synchronization (`cam_hs`) and vertical synchronization (`cam_vs`). During the image-sensor readout, these signals define when a row of valid data begins and ends, and when a frame starts and ends.

NOTE: For correct operation, the clock `cam_pclk` must run during blanking periods (`cam_hs` and `cam_vs` inactive). `cam_pclk` must start before sending `cam_d` and start `cam_vs` and `cam_hs`.

[Figure 6-2](#) and [Figure 6-3](#) show the frame and data timing, respectively, based on synchronization signals in the parallel No BT configuration.

Figure 6-2. Camera ISP Synchronization Signals and Frame Timing in SYNC Mode

Figure 6-3. Camera ISP Synchronization Signals and Data Timing in SYNC Mode

NOTE: The pixel clock can be gated to qualify valid pixels. It can also be gated during blanking periods to reduce power consumption. However, at least 4 clock pulses are required before sending active image data and synchronization information; 8 clock pulses are required after the end of active video. Extra-clock pulses are allowed but not required during the line blanking periods.

[Figure 6-4](#) shows the timing diagram of the SYNC mode clock gating.

Figure 6-4. Camera ISP SYNC Mode Clock Gating

6.2.4.2 Camera ISP Parallel Generic Configuration: JPEG Sensor Connection on the Parallel Interface

Some camera modules integrate an image-signal processor (ISP) and a JPEG encoder. The CCDC can interface with these camera modules and transfer the received JPEG stream to memory.

To use this mode, set the `ISP_CTRL` [30] `JPEG_FLUSH` bit.

Figure 6-5 shows timing diagrams for an JPEG stream.

Figure 6-5. Camera ISP JPEG Stream Timing Diagrams**CAUTION**

The bridge cannot be used for JPEG sensor connections.

6.2.4.3 Camera ISP ITU-R BT.656 Protocol and Data Formats (8, 10 Bits)

CAUTION

The ITU-R BT.656 mode cannot be used when the bridge is enabled.

The camera ISP interface supports data in ITU-R BT.656 format.

The ITU-R BT.656 standard specifies a method of transferring YUV422 data over an 8- or 10-bit video interface.

Figure 6-6 shows the data timing diagram with embedded synchronization signal.

Figure 6-6. Camera ISP Data Timing With Embedded Synchronization Signals (8-Bit Case)

In BT.656, the data words (8- or 10-bit) in which the eight most-significant bits (MSBs) are all set to 1, or all set to 0 are reserved. Only 254 of the possible 256 8-bit word values, and 1016 of the possible 1024 10-bit word values represent signal values.

The data is multiplexed in the following order: Cb0 Y0 Cr0 Y1 Cb2 Y2 Cr2 Y3, etc., where the byte sequence Cb2n Y2n Cr2n refers to interleaved luminance and chroma samples and the following byte Y2n + 1 corresponds to the next luminance sample.

The BT.656 protocol uses unique timing reference signals embedded in the video stream. The synchronization signals cam_hs and cam_vs are not needed. This reduces the number of wires required for a BT.656 video interface.

There are two timing reference codes: The start of active video (SAV) reference code precedes each video data block, and the end of active video (EAV) follows each video data block. Each timing reference signal consists of a 4-byte sequence in the following hexadecimal format: **FF 00 00 XY**. The first 3 bytes are a fixed preamble (see the ITU-R BT.656 specification). The fourth byte (XY) contains information defining field identification (F), blanking (V), and SAV/EAV information (H), and 4 parity bits calculated as a function of F, V, and H (see the ITU-R BT.656 specification).

Table 6-4 lists the video timing reference codes for SAV and EAV.

Table 6-4. Camera ISP Video Timing Reference Codes for SAV and EAV

Data Bit Number	First Word (FF)	Second Word (00)	Third Word (00)	Fourth Word (XY)
9 (MSB)	1	0	0	1
8	1	0	0	F
7	1	0	0	V
6	1	0	0	H
5	1	0	0	P3
4	1	0	0	P2
3	1	0	0	P1
2	1	0	0	P0
1	1	0	0	0
0	1	0	0	0

Table 6-5 contains a description of the F, V, and H signals.

Table 6-5. Camera ISP F, V, H Signal Descriptions

Signal	Value	Command
F	0	Field 1
	1	Field 2
V	0	0
	1	Vertical blank
H	0	SAV
	1	EAV

The resulting Hamming distance between any two code words is four, allowing two error detections and one error correction. To enable or disable the error-correcting capability, configure the [CCDC_REC656IF \[1\] ECCFVH](#) bit.

NOTE: The 2-bit errors are detected, but not flagged or corrected. Errors of more than 2 bits are not corrected or flagged.

[Table 6-6](#) lists the F, V, and H protection (error-correction) bits.

Table 6-6. Camera ISP F, V, H Protection (Error-Correction) Bits

F	V	H	P3	P2	P1	P0
0	0	0	0	0	0	0
0	0	1	1	1	0	1
0	1	0	1	0	1	1
0	1	1	0	1	1	0
1	0	0	0	1	1	1
1	0	1	1	0	1	0
1	1	0	1	1	0	0
1	1	1	0	0	0	1

When operating in CCIR-656 mode, data is stored in SDRAM according to the format shown in [Table 6-7](#) when [CCDC_SYN_MODE \[11\] PACK8](#) is enabled.

Table 6-7. Camera ISP BT.656 Mode Data Format in SDRAM

8 bit x 4	Pixel3 (Y1/Cr0)	Pixel2 (Cr0/Y1)	Pixel1 (Y0/Cb0)	Pixel0 (Cb0/Y0)
	Bit 31			Bit 0

NOTE: The CCDC outputs the XY code in the SAV and EAV into memory. To eliminate this, users must set the SPH register field to +1. In addition, the NPH register field must be set to accurately represent the number of active pixels.

6.2.4.4 Camera ISP CSI1/CCP2 Protocol and Data Formats

The CSI1/CCP2B receiver supports two protocols:

- MIPI CSI1 protocol
- CCP2 protocol

The MIPI CSI1 protocol is compatible with the CCP2 protocol with the following constraints:

- Class 0 CCP2 sensors are used: Data/clock
- No RAW6 or RAW7 data types
- No CRC code generation
- Only one logical channel: Channel 0
- No DPCM

This section describes CSI1/CCP2B protocol and data formats. [Table 6-8](#) describes the I/O for serial interface CSI1/CCP2B.

Moreover, the CSI1/CCP2B receiver is a serial interface to an image sensor. Data is taken from pins and through the configured associated PHY taken to the receiver (for information about initializing and configuring the CSIPHY, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver](#)). The receiver on its side, can send data to the Video processing hardware or memory.

The CSI1/CCP2B receiver interface has several image-data operating modes, summarized in [Table 6-8](#).

Table 6-8. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

NOTE:

- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros
CCP2_LCx_CTRL [15:8] ALPHA can be used to set an alpha value.
For RGB444 + EXP16:
 - data_out[31:28] = ALPHA[3:0] and data_out[27:16] = RGB444
 - data_out[15:12] = ALPHA[3:0] and data_out[11:0] = RGB444
- EXP32 = Data expansion to 32 bits, padding with alpha
CCP2_LCx_CTRL [15:8] ALPHA can be used to set an alpha value.
For RGB888 + EXP32: data_out[31:24] = ALPHA[7:0] and data_out[23:0] = RGB888
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the video processing hardware is enabled. The programmer must ensure that only one logical channel is enabled to the Video processing hardware. The behavior of the video processing hardware is unpredictable if several logical channels to it are enabled simultaneously.

The preamble 0xFF0000 is fixed by construction and must not be modified. However, the CSI1/CCP2B receiver programming model allows the synchronization code identifier to be overwritten: bits 0 to 3.

Every code is transmitted byte-wise, least-significant bit (LSB) first. For example, the code 0xFF00:0002 transmitted from the image sensor corresponds to the following bitstream: 11111111 - 00000000 - 00000000 - 01000000. Every default code starts with a set of eight 1s and sixteen 0s that are never received in pixel data. This means that content having eight 1s and sixteen 0s is not allowed. [Figure 6-7](#) shows an example of 0xFF00 0002 transmission.

camisp-182

The line length sent through the associated configured PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits and the number of lines is even to correctly finish the pixel reconstruction.

The line structure is different for odd and even lines. Odd lines transport the U component, while even lines contain the V component. This is shown in [Figure 6-10](#).

Figure 6-10. Camera ISP CSI1/CCP2 YUV420

camisp-183

6.2.4.4.1.2 Camera ISP CSI1/CCP2 RGB Pixel Data Formats

RGB888 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits to correctly finish pixel reconstruction.

Figure 6-11 shows an example of RGB888 format.

Figure 6-11. Camera ISP CSI/CCP2 RGB888

For RGB565, the line length sent through the associated PHY is a multiple of 32 bits (see [Figure 6-12](#)).

camisp-184

Figure 6-12. Camera ISP CSI1/CCP2 RGB565

RGB444 data format is output to memory with data expansion. If data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the associated PHY is a multiple of 32 bits (see Figure 6-13).

Figure 6-13. Camera ISP CSI1/CCP2 RGB444

6.2.4.4.1.3 Camera ISP CSI1/CCP2 RAW Bayer RGB Pixel Data Formats

6.2.4.4.1.3.1 Camera ISP CSI1/CCP2 RAW6 (CCP2 Only)

RAW6 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line is a multiple of 3 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 6 is 96; that is 3 x 32 bits).

Figure 6-14 shows RAW6 format.

NOTE: The RAW6 data format do not apply to the MIPI CSI1 compatible mode.

Figure 6-14. Camera ISP CSI1/CCP2 RAW 6

6.2.4.4.1.3.2 Camera ISP CSI1/CCP2 RAW7 (CCP2 Only)

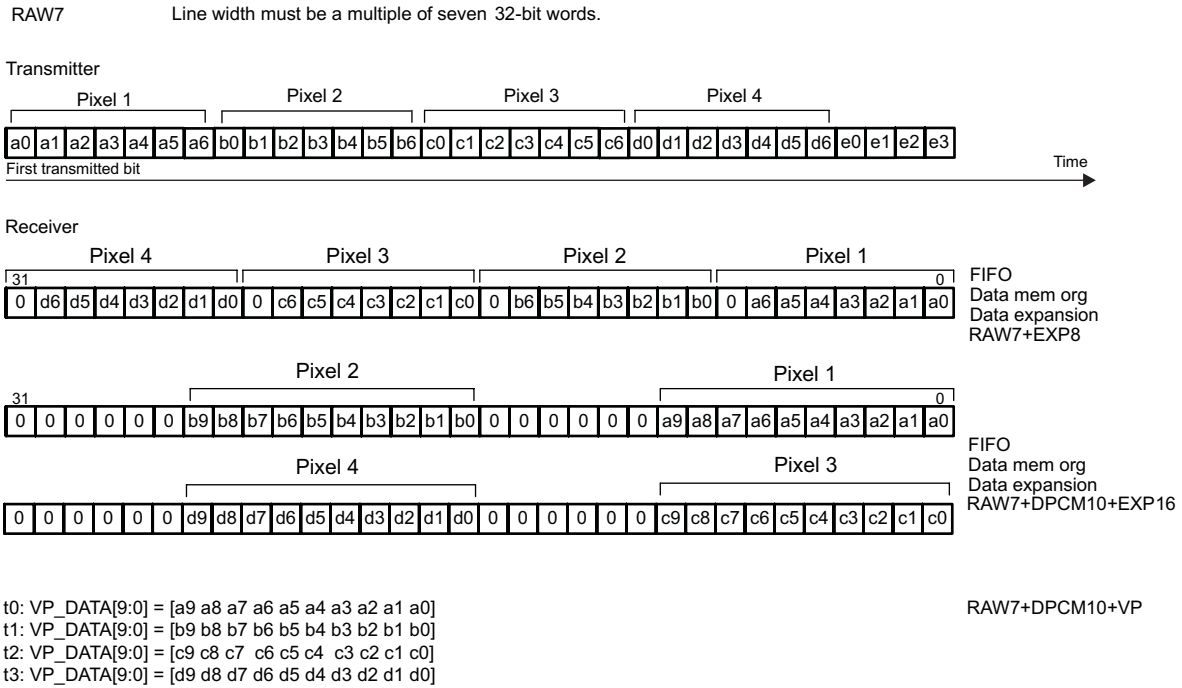

RAW7 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 7 x 32 bits to correctly finish the pixel reconstruction (the lowest common multiple of 32 and 7 is 224; that is, 7 x 32 bits).

Figure 6-15 shows RAW7 format.

NOTE: The RAW7 data format do not apply to the MIPI CSI1 compatible mode.

Figure 6-15. Camera ISP CSI1/CCP2 RAW 7

6.2.4.4.1.3.3 Camera ISP CSI1/CCP2 RAW8

RAW8 data format can be output to memory in two formats: with no data expansion and with data expansion.

The line length sent through the associated PHY is a multiple of 32 bits.

Figure 6-16 shows RAW8 format.

NOTE:

- Use RAW8 data format to output RAW6 and RAW7 data formats to memory.
- Use YUV422 + VP to output RAW8 data to the video port: YUV422 + VP is equivalent to RAW8 + VP.

Figure 6-16. Camera ISP CSI1/CCP2 RAW8

RAW8 + VP

camisp-189

6.2.4.4.1.3.4 Camera ISP CSI1/CCP2 RAW10

RAW10 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word.

The line length sent through the associated PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 5 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 10 is 320: 10 x 32 bits).

RAW10 data format can be sent to the video port.

Figure 6-17 shows RAW10 format.

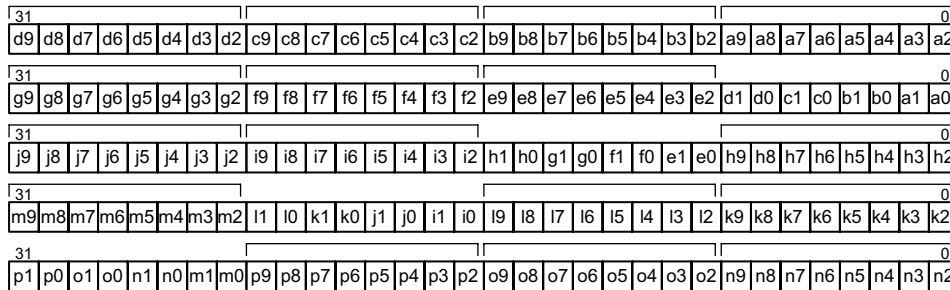

Figure 6-17. Camera ISP CSI1/CCP2 RAW10

camisp-190

6.2.4.4.1.3.5 Camera ISP CSI1/CCP2 RAW12

RAW12 data format can be output to memory in two formats: with no data expansion and with data expansion.

If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word.

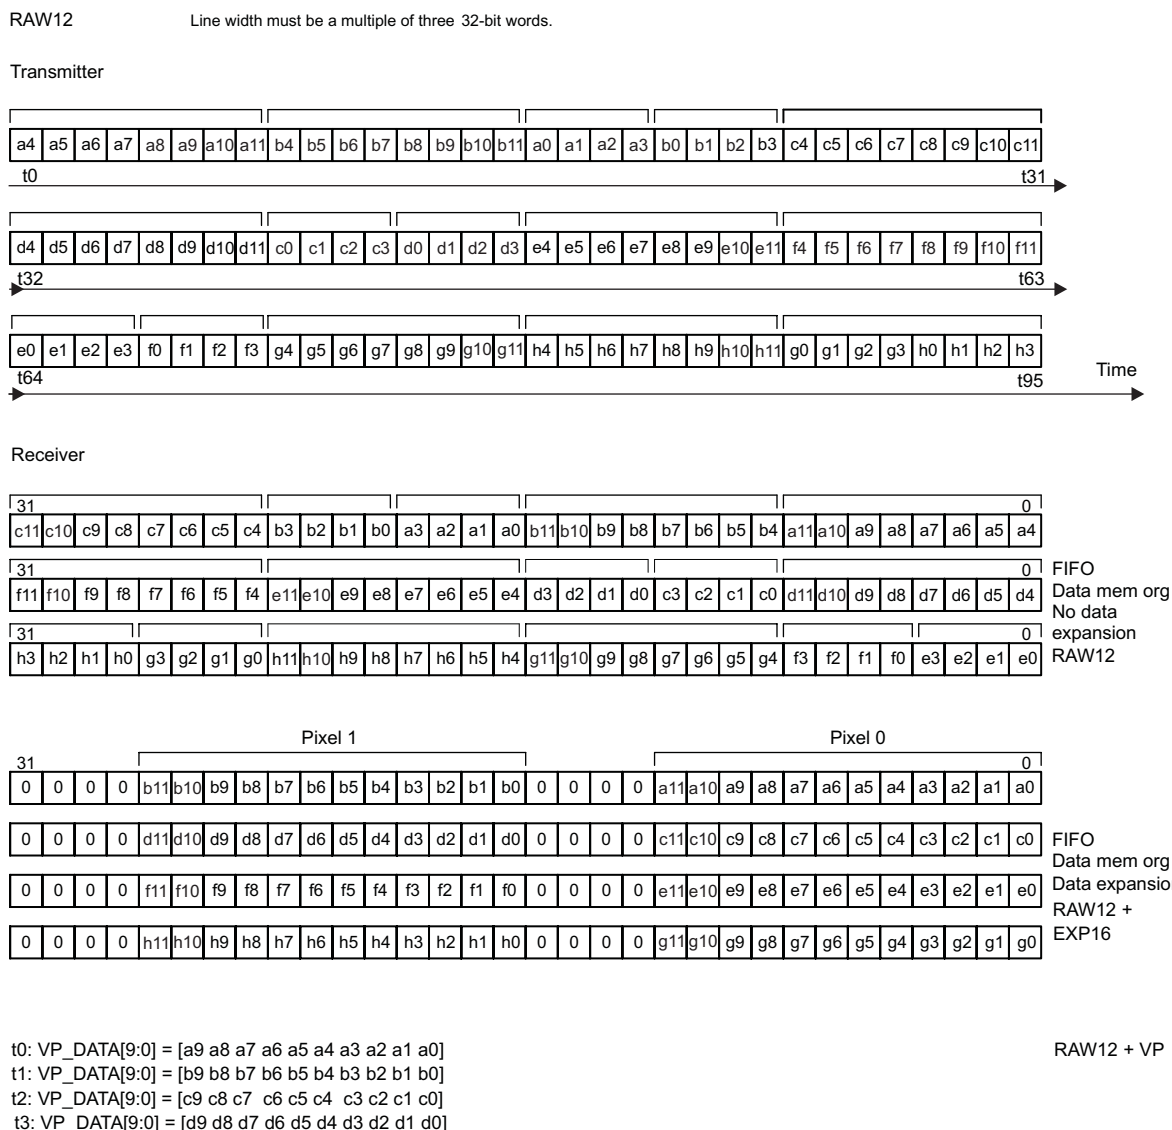

The line length sent through the PHY is a multiple of 32 bits. Furthermore, the line length is a multiple of 3 x 32 bits to correctly finish pixel reconstruction (the lowest common multiple of 32 and 12 is 96: 3 x 32 bits).

RAW12 data format can be sent to the video port.

Figure 6-18 shows RAW12 format.

NOTE: The video processing hardware is 10-bit only. Typically, the data lane shifter must be used to perform 10-bit-only processing.

Figure 6-18. Camera ISP CSI1/CCP2 RAW12

camisp-191

6.2.4.4.1.4 Camera ISP CSI1/CCP2 JPEG8 Pixel Data Formats

The line length sent through the associated PHY is a multiple of 32 bits. The false synchronization protection (FSP) code insertion on the transmitter side automatically ensures this line length. It is impossible to know in advance the size of a compressed stream. Figure 6-19 shows JPEG8 and JPEG8 FSP format.

Figure 6-19. Camera ISP CSI1/CCP2 JPEG8 and JPEG8 FSP

In JPEG8 mode, the JPEG encoder on the sensor side must avoid generating data equal to the synchronization code and must deliver a synchronization-code-free bitstream.

In JPEG8 FSP mode, the bitstream is a standard JPEG8 bitstream in which byte-stuffing is used to differentiate synchronization code from original data with the same value. Thus, the JPEG encoder can generate a standard bitstream, and a postprocessing stage (FSP encoder) is used to highlight natural bitstream data equal to synchronization codes, so that the other end can discard the false synchronization codes.

FSP decoding is performed for byte-aligned data and occurs after the frame-start synchronization code is received. If the byte n = 0x0, the FSP decoder looks for bytes 1 and 2. If the bytes are equal to an illegal combination (synchronization codes), the byte 0xA5 that comes after (byte n + 1) is removed from the bitstream.

The 0xA5 padding bytes at the end of the frame are also removed by FSP decoding so that padding does not generate additional data in the FIFO. FSP decoding is then transparent to the software.

Normally, the module detects the illegal combination and then the 0xA5. When the 0xA5 is corrupted or replaced by another code, the value is automatically removed from the bitstream and an interrupt is generated to signal that the code is corrupt and therefore the received data are suspicious. If the line is too noisy for FSP decoding, it is better to configure the subsystem in JPEG8 and use software postprocessing.

6.2.4.5 Camera ISP CSI2 Protocol and Data Format

NOTE: The two CSI2 receivers (CSI2A and CSI2C) support MIPI CSI2.

6.2.4.5.1 Camera ISP CSI2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2 receiver core depends on the lane configuration.

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

The lane merger can merge up to four lanes into a single byte stream.

In case of a single lane, the lane merger is not used to merge byte streams.

Figure 6-20 and Figure 6-21 show an example of byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

Figure 6-20. Camera ISP CSI2 Two Data-Lane Merger Configuration

camisp-239

Figure 6-21. Camera ISP CSI2 One Data-Lane Configuration

camisp-240

6.2.4.5.2 Camera ISP CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 6-22 shows the CSI2 protocol layer with short and long packets.

Figure 6-22. Camera ISP CSI2 Protocol Layer With Short and Long Packets

Key:
 ST: Start of transmission ET: End of transmission
 PH: Packet header PF: Packet footer
 ULPM: Ultra-low power mode SP: Short packet

camisp-241

Two packets are always separated from each other with a sequence of a ULPM, an ET, and an ST.

6.2.4.5.2.1 Camera ISP CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. Figure 6-23 shows the structure of a short packet.

Figure 6-23. Camera ISP CSI2 Short Packet Structure

camisp-242

For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0. The frame number is inoperative.
- The frame number increments by 1 for every FS packet with the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For line-start code (LSC) and line-end code (LEC) synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0. The line number is inoperative.
- The line number increments by one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended usage is for progressive scan (non-interlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than one for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be

different between successive frames. The intended usage is for interlaced video data streams.

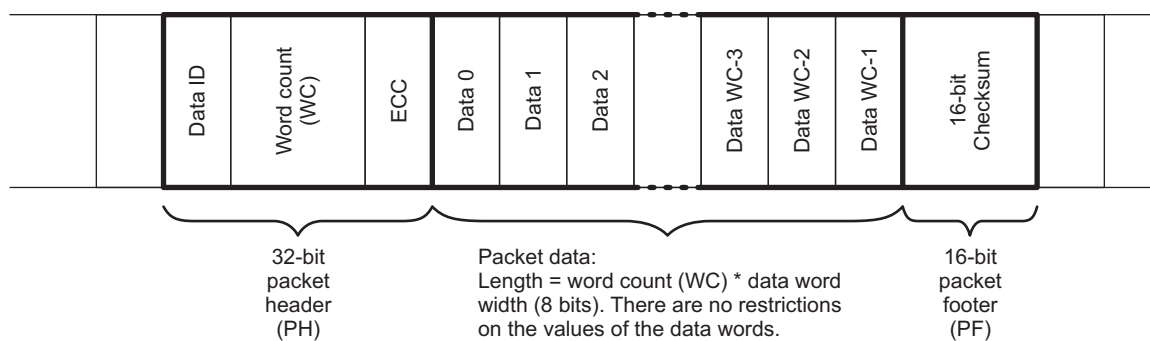

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (there are up to eight contexts to support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

6.2.4.5.2.2 Camera ISP CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements: a 32-bit packet header (PH), an application-specific data payload with a variable number of 8-bit data words, and a 16-bit packet footer (PF). The packet header is further composed of three elements: an 8-bit data identifier, a 16-bit word count field, and an 8-bit ECC. The packet footer has one element, a 16-bit checksum. Figure 6-24 and Table 6-9 show the structure of a long packet.

Figure 6-24. Camera ISP CSI2 Long Packet Structure

camisp-243

Table 6-9. Camera ISP CSI2 Long Packet Structure Description

Packet Part	Field Name	Size (Bit)	Description
Header	Data ID	8	Contains the virtual channel identifier and the data-type information
	Word count	16	Number of data words in the packet data. A word is 8 bits.
	ECC	8	ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection.
Data	Data	WC * 8	Application-specific payload (WC words of 8 bits)
Footer	Checksum	16	16-bit cyclic redundancy check (CRC) for packet data

There are no restrictions on packet data size, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

6.2.4.5.2.3 Camera ISP CSI2 Data Identifier

The data identifier byte contains the virtual channel identifier (VC) value and the data-type (DT) value, as shown in Figure 6-25. The VC is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 6-25 shows the data identifier structure.

Figure 6-25. Camera ISP CSI2 Data Identifier Structure

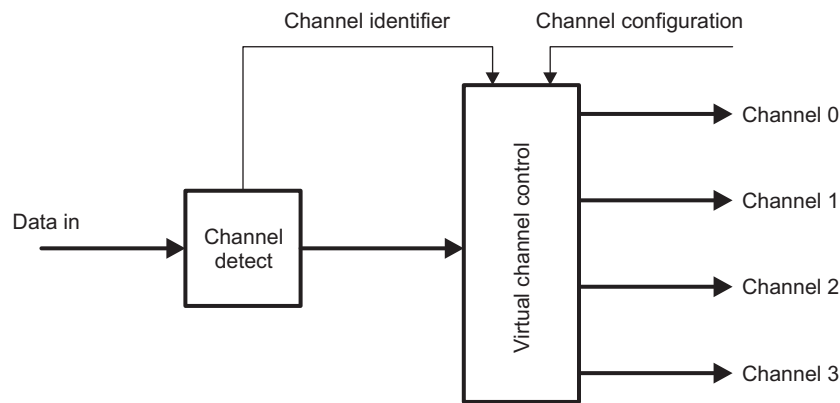

camisp-244

Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built up of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. The following synchronization codes are optional for the transmitter: line start and line end. A set of registers is associated with each context defined by the virtual channel ID and the data type. [Figure 6-26](#) shows a virtual channel.

Figure 6-26. Camera ISP CSI2 Virtual Channel

For more information on how the data formats are transmitted and how the data are stored in memory, see [Section 6.2.4.5.3, Camera ISP CSI2 Pixel Data Format](#).

6.2.4.5.2.4 Camera ISP CSI2 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bit-stream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the current frame

[Table 6-11](#) summarizes the synchronization code values.

Table 6-11. Camera ISP CSI2 Synchronization Codes

Synchronization Code	Value	Comments
FSC	0x0	Mandatory
FEC	0x1	Mandatory
LSC	0x2	Optional
LEC	0x3	Optional
Reserved	0x4 to 0x7	Not used

6.2.4.5.2.5 Camera ISP CSI2 Generic Short Packet Codes

When the synchronization code value is between 0x8 and 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

6.2.4.5.2.6 Camera ISP CSI2 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit non-image data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

6.2.4.5.2.7 Camera ISP CSI2 Frame Structure

Each frame consists of short packets to indicate start of frame and end of frame. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as start-of-frame (SOF) and end-of-frame (EOF) information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame comprises embedded data and image-sensor data. [Figure 6-27](#) shows where the embedded data and image sensor data are in the frame. The following definitions apply:

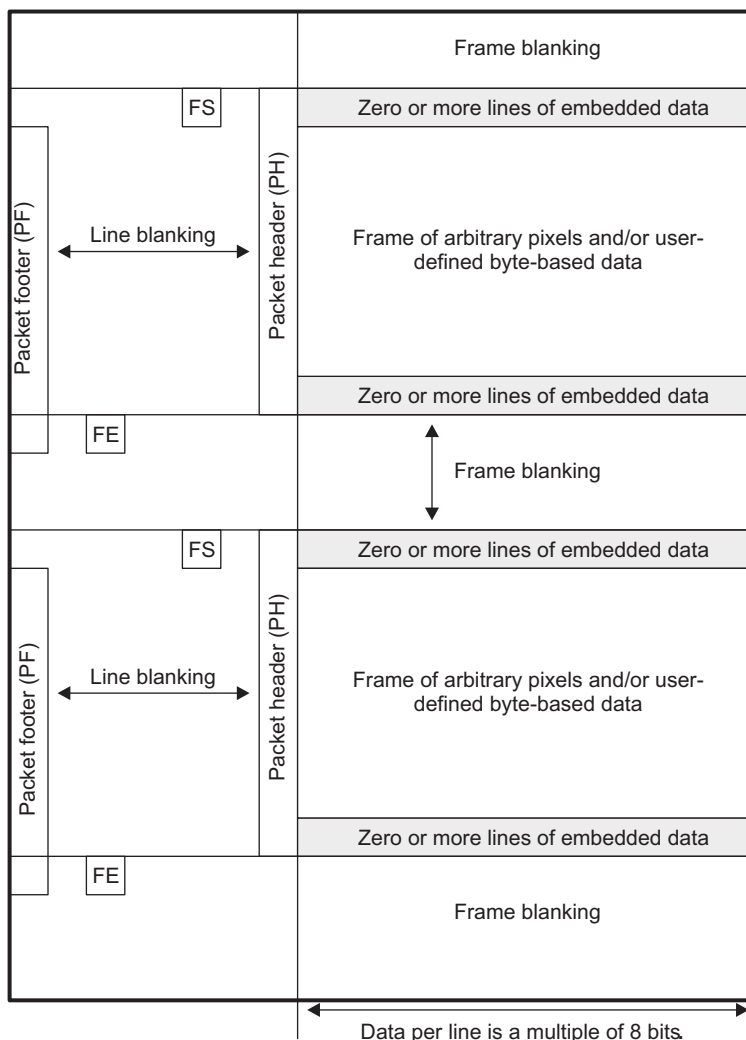

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image data comprises pixels of the same or different data formats.
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for software use.

Because the data types are different, the CSI2 receiver uses a different context for embedded data and image-sensor data.

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

Figure 6-27. Camera ISP CSI2 General Frame Structure (Informative)

Key:

PH: Packet header
 FS: Frame start

PF: Packet footer
 FE: Frame end

camisp-246

Figure 6-28 shows the frame structure of a YUV422 interlaced video frame without embedded data.

Figure 6-28. Camera ISP CSI2 Digital Interlaced Video Frame (Informative)

Key:
 PH: Packet header
 FS: Frame start
 LS: Line start
 PF: Packet footer
 FE: Frame end
 LE: Line end

camisp-247

The period between the LEC and the new LSC is the line blanking period. The time between the FEC and the new FSC is the frame blanking period. The receiver works with the line blanking period set to 0.

6.2.4.5.3 Camera ISP CSI2 Pixel Data Format

6.2.4.5.3.1 Camera ISP CSI2 YUV Pixel Data Format

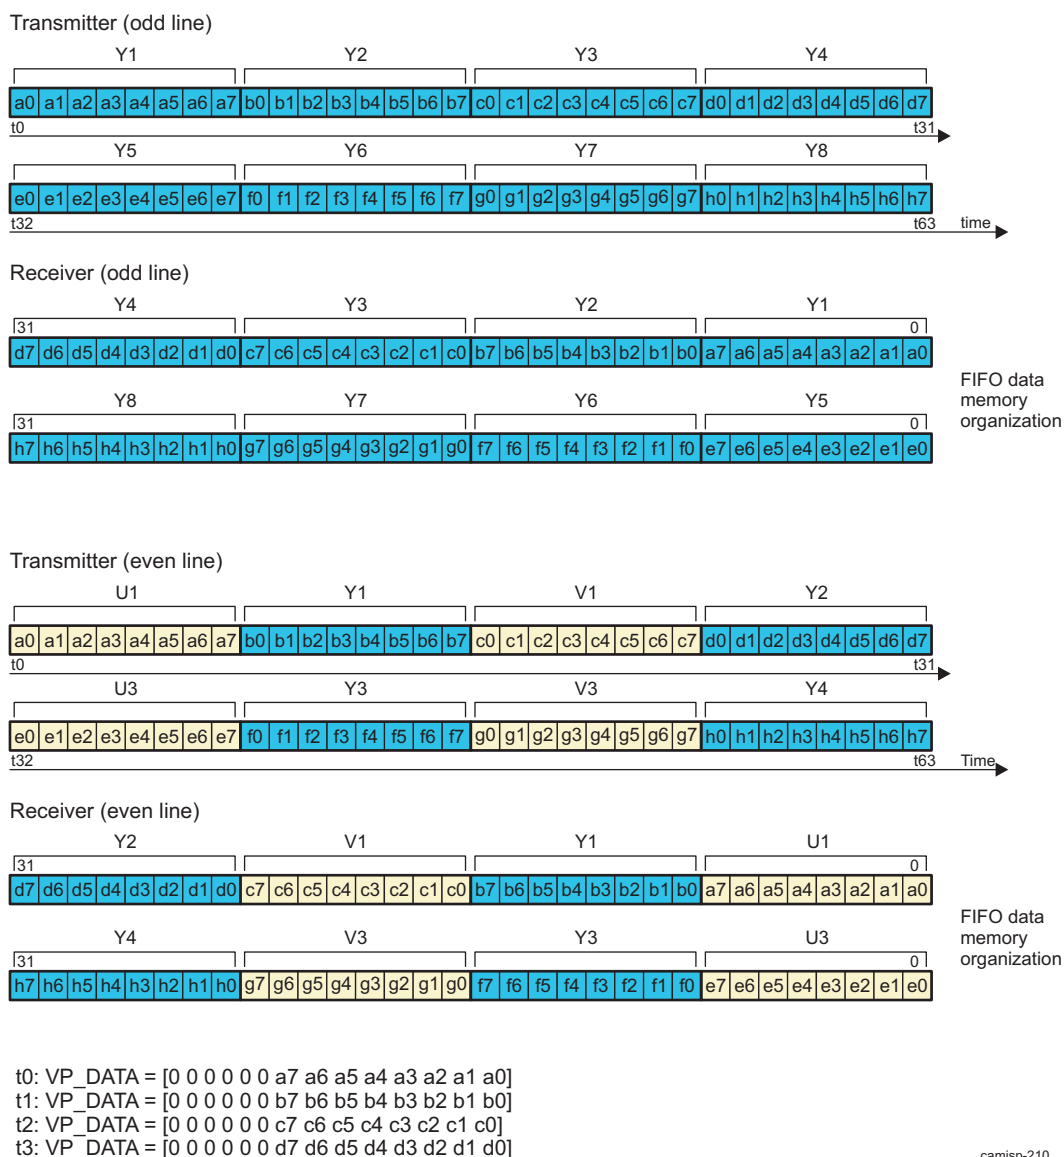

6.2.4.5.3.1.1 Camera ISP CSI2 YUV420 8-Bit

YUV420 8-bit data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3*32 bits and the number of lines must be even. Figure 6-29 shows the storage format for YUV420 8-bit data.

Figure 6-29. Camera ISP CSI2 YUV420 8-Bit

YUV420 8-bit

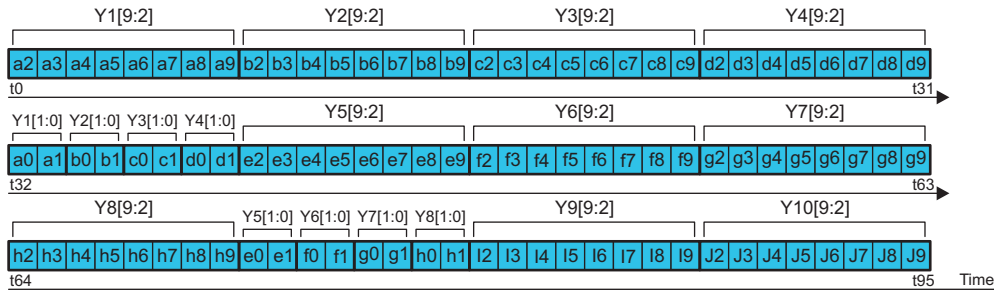

6.2.4.5.3.1.2 Camera ISP CSI2 YUV420 10-Bit

YUV420 10-bit data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 40 bits for odd lines and 80 bits for even lines. Figure 6-30 shows the storage format for YUV420 10-bit data.

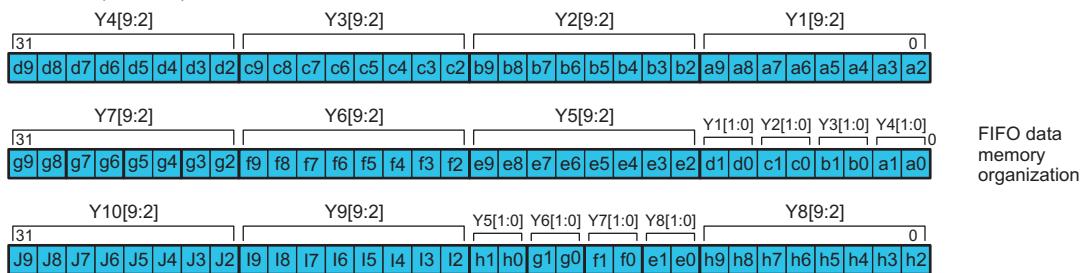

Figure 6-30. Camera ISP CSI2 YUV420 10-Bit

YUV420 10-bit

6.2.4.5.3.1.3 Camera ISP CSI2 YUV420 8-Bit Legacy

YUV420 8-bit legacy data can be stored to memory in big-endian format. The line length sent through the CSI2 physical protocol is a multiple of 4 bytes. Figure 6-31 shows the storage format for YUV420 8-bit legacy data.

Figure 6-31. Camera ISP CSI2 YUV420 8-Bit Legacy

YUV420 8-bit legacy

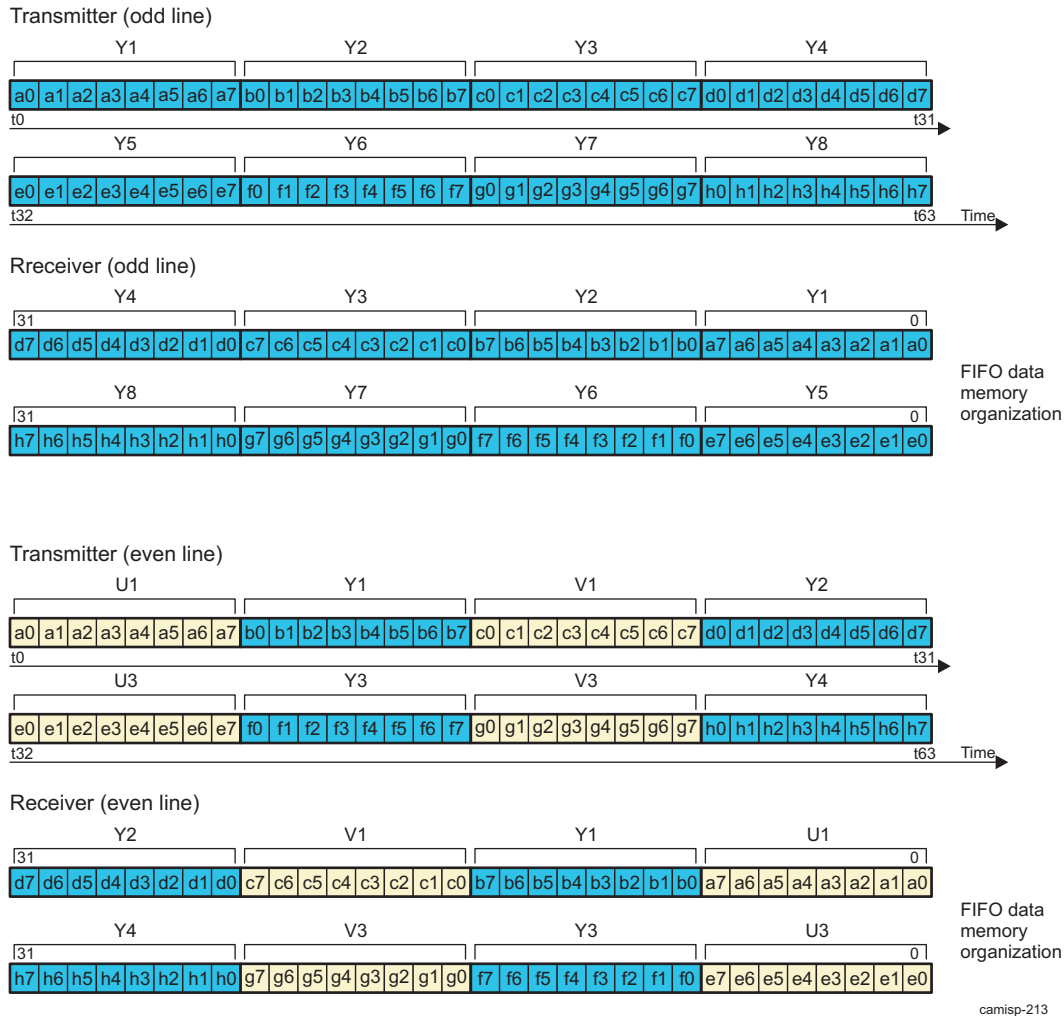

6.2.4.5.3.1.4 Camera ISP CSI2 YUV420 8-Bit + CSPS

YUV420 8-bit CSPS data can be stored to memory in little-endian format. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 3*32 bits and the number of lines must be even. Figure 6-32 shows the storage format for YUV420 8-bit + CSPS data.

**6.2.4.5.3.5 Camera ISP CSI2 Generic Format**

The CSI2 receiver supports a generic format to send data to memory and/or the video port. The generic mode is entered by setting the `CSI2_CTX_CTRL1[30]` GENERIC bit. The `CSI2_CTX_CTRL2[9:0]` FORMAT register defines how the data stream is decoded. When generic mode is enabled (GENERIC = 1), MIPI data type code is ignored and data is decoded using the FORMAT bit. Whatever the MIPI data type code, it is ignored (the data stream is processed even if the FORMAT bit does not match the MIPI data type code). When generic mode is not used (GENERIC = 0), the data stream is processed only when the MIPI data type code matches the FORMAT setting of the enabled context. If it does not match, the data stream is not processed by the CSI2 engine. Only the virtual channel information is used to map a received data stream to a context. Software must ensure that a MIPI virtual channel used in generic mode is only mapped to a single context.

Figure 6-48. Camera ISP CSI2 GenericISS CSI2 Generic: `CSI2_CTX_CTRL1_i[30]` GENERIC = 0x1

Transmitter

Receiver when, for example, `CSI2_CTX_CTRL2[9:0]` FORMAT = RAW8**6.2.4.5.3.6 Camera ISP CSI2 Byte-Swap**

The CSI2 receiver incorporates a byte-swap function. Software can optionally enable byte-swapping of the payload data by setting the `CSI2_CTX_CTRL1[31]` BYTESWAP bit. This feature must only be used when the amount of payload data per packet is a multiple of 16 bits. The byte-swapping is performed before pixel reconstruction.

6.3 Camera ISP Integration

Figure 6-50 shows the Camera ISP integration.

Figure 6-50. Camera ISP Integration

6.3.1 Camera ISP Clocking, Reset, and Power-Management Scheme

6.3.1.1 Camera ISP Clocks

There are six clock domains in the camera ISP:

- Functional clock domain, this clock is from L3 interconnect along with Interface master write port clock. It is required to be 2x faster than the pixel clock.
- CSI1/CCP2B Serial interface clock domain. Only the parallel mode between the PHYs and the ISP is used.

- CSI2 serial interface clock domain
- CSI2 byte clock domain, whose frequency depends on the image sensor type and size, its frame rate and its blanking period. The clock is generated from the bit-clock from the sensor and converted into byte clock.
- Parallel interface clock domain. This frequency depends on the imaging sensor type and size, its frame rate and its blanking time. The functional clock is required to be at least 2x faster than the pixel clock when the bridge is disabled and a least equal when it is enabled.
- Slave interface clock domain, from L4 interconnect

6.3.1.1.1 Camera ISP Clock Tree

Figure 6-51 shows the clock tree for the camera ISP module.

Figure 6-51. Camera ISP Clock Tree Diagram

6.3.1.1.2 Camera ISP Clock Descriptions

Table 6-12 describes the camera ISP clocks.

Table 6-12. Camera ISP Clock Descriptions

Signal Name	IO	Description
CAM_FCLK	Input	Functional clock (L3 interconnect clock domain) Functional clock domain.
CAM_ICLK	Input	Interface clock (L4 interconnect clock domain) Interface clock domain.
CAM_MCLK ⁽¹⁾	Input	Internal clock from PRCM at 216 MHz. The CAM_MCLK is used by the clock generator to generate cam_xclka and cam_xclkb. It is also used by the control Signal generator to generate cam_shutter, cam_strobe, and cam_global_reset. For more information, see Section 6.4.4, Camera ISP Timing Control.
cam_xclka	Output	External clock for the image-sensor module. For serial or parallel sensor.

⁽¹⁾ The CAM_MCLK frequency can be less than, or equal to 216 MHz.

Table 6-12. Camera ISP Clock Descriptions (continued)

Signal Name	IO	Description
cam_xclkb	Output	External clock for the image-sensor module. For serial or parallel sensor.
cam_pclk	Input	Parallel mode: pixel clock for parallel input data. The data on the parallel interface are presented on cam_d, one pixel for every cam_pclk rising or falling edge. Parallel sensor clock domain.
CSI2_96M_FCLK	Input	CSI2 functional clock driven by PRCM.CM_FCLKEN_CAM[1] EN_CSI2.

6.3.1.1.3 Camera ISP Clock Configuration

- CSI2_96M_FCLK is the CSI2 functional clock running at 96 MHz and enabled when PRCM.CM_FCLKEN_CAM[1] EN_CSI2 = 1
- CAM_FCLK control and settings

The CAM_FCLK clock runs at the device L3 clock frequency.

The CAM_FCLK source is the PRCM CAM_L3_ICLK output.

When the camera ISP no longer needs CAM_FCLK, the software can disable it at PRCM level by setting the PRCM.CM_ICLKEN_CAM [0] EN_CAM bit to 0x0. The clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). For information, note that an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_FCLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_FCLK clock along with the CAM power domain at PRCM level. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- CAM_ICLK control and settings:

CAM_ICLK is the interface clock. It runs at device L4 interconnect clock speed and triggers access to the camera ISP L4 interface. Its source is the PRCM CAM_L4_ICLK output.

When the camera ISP no longer needs CAM_ICLK, the software can disable it at PRCM level by setting to 0x0 the PRCM.CM_ICLKEN_CAM [0] EN_CAM bit. The clock is not effectively shut down until the camera ISP module has reached the IDLE state (that is, it does not generate anymore traffic on the device interconnect and is internally idled). As information, note an automatic HW handshake protocol takes place between the camera ISP and the PRCM to prevent CAM_ICLK from being cut while the module is processing or transferring data.

An autoidle mode can be activated for this clock (PRCM.CM_AUTOIDLE_CAM [0] AUTO_CAM bit set to 1). This allows global management of the CAM_ICLK clock along with the CAM power domain at PRCM level. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- CAM_MCLK control and settings:

The source for CAM_MCLK is the PRCM CAM_MCLK output. It is generated through a peripheral DPLL and its frequency can be adjusted using the PRCM.CM_CLKSEL_CAM[4:0] CLKSEL_CAM bit field.

When the module no longer needs it, it can be disabled at PRCM level by setting the PRCM.CM_FCLKEN_CAM[0] EN_CAM bit to 0x0. The PRCM register bit setting has a direct effect on the clock; in other terms, there is no HW handshake protocol to ensure whether the clock can be cut regarding the camera ISP activity: as soon as the bit is set to 0x0, CAM_MCLK is shut down.

- cam_xclka and cam_xclkb control and settings:

cam_xclka and cam_xclkb are generated inside the camera ISP module from CAM_MCLK clock input. [Table 6-13](#) and [Table 6-14](#) give the settings of the related bit fields.

Table 6-13. Camera ISP cam_xclka Configuration

ref_clk	CAM.TCTRL_CTRL[4:0] DIVA field	cam_xclka
CAM_MCLK	0x0	Stable low level. Divider disabled.
	0x1	Stable high level. Divider disabled.

	0x1	Stable high level. Divider disabled.
	0x2	CAM_MCLK/2

	0x1F	CAM_MCLK

6.3.1.2 Camera ISP Power Management

Power consumption can be reduced at two different levels:

- A local power-management optimization
- A system power management

6.3.1.2.1 Camera ISP Local Power Management

To optimize power consumption, a local autoidle feature is implemented on the CAM_ICLK interface clock at camera ISP module level. By enabling this autoidle feature, CAM_ICLK is automatically gated at the module boundary as soon as it is not required and restarted without any latency when needed again. This allows power saving when the module is not involved in any transfer from/to the device interconnect. This autoidle feature is enabled by setting:

- [ISP_SYSCONFIG](#) [0] AUTO_IDLE bit to 1
- [CCP2_SYSCONFIG](#) [0] AUTO_IDLE bit to 1
- [CSI2_SYSCONFIG](#) [0] AUTO_IDLE bit to 1
- MMU.MMU_SYSCONFIG [0] AUTOIDLE bit to 1
- [ISP_CTRL](#) [21] SBL_AUTOIDLE bit to 1

The decision to gate the interconnect clock is based on interface activity, regardless of hardware handshake protocols.

After a reset, this mode is enabled, by default.

NOTE: It is recommended that this mode be enabled to reduce power consumption.

6.3.1.2.2 Camera ISP System Power Management

As part of the system power management scheme, the camera ISP module interacts with the PRCM through an automatic standby hardware protocol that allows dynamic power savings at CAMERA power domain level.

Being an initiator on the L3 interconnect, the camera ISP module alerts the PRCM as soon as it is ready to switch to a lower power state. Prior to any power state change to the CAMERA power domain, the PRCM first shuts off the camera clocks, depending on the camera ISP behavior and the clock settings at PRCM level. Namely, as soon as the camera ISP is ready to go to STANDBY, it asserts an automatic HW STANDBY request to the PRCM, which shuts down the clocks if they have been previously disabled by software and then potentially change the CAMERA power domain state. Refer to [Chapter 3, Power, Reset, and Clock Management](#), for further details.

When it goes to standby, the camera ISP module alerts the PRCM differently, depending on the [ISP_SYSCONFIG](#) [13:12] MIDDLE_MODE bit field settings. The entry conditions for the camera ISP to go into standby mode are:

- The module has finished any current transaction and does not generate any more traffic on the interconnect.
- The module is idle (on-going transactions are finished).

The MIDDLE_MODE bit field allows the following settings for the camera ISP module:

- Force standby

The camera ISP is set to force standby when MIDDLE_MODE is set to 0x0. In this mode, the camera ISP module asserts its HW standby request to the PRCM as soon as it is disabled. Namely, the camera ISP is disabled when the following bit fields are set to 0x0:

- [ISP_CTRL](#) [13] RSZ_CLK_EN
- [ISP_CTRL](#) [12] PRV_CLK_EN
- [ISP_CTRL](#) [11] HIST_CLK_EN
- [ISP_CTRL](#) [10] H3A_CLK_EN
- [ISP_CTRL](#) [8] CCDC_CLK_EN

Moreover, CSI2A and CSI2C receivers must also be disabled by setting the related [CSI2_CTRL](#)[0] IF_EN bits to 0x0 and CSI1/CCP2B must also be disabled by setting the related [CCP2_CTRL](#) [0] IF_EN bits to 0x0.

- No standby

The camera ISP is set to no standby when MIDDLE_MODE is set to 0x1. In this mode, the camera ISP module never asserts its standby request to the PRCM. This also prevents the CAMERA power domain from going to a lower power state. Refer to [Chapter 3, Power, Reset, and Clock Management](#), for further details.

- Smart standby

The camera ISP module is set to smart standby when MIDDLE_MODE is set to 0x2. In this mode, the camera ISP module asserts its HW standby request to the PRCM according with its internal activity (namely, when there is no more activity on the camera ISP master interface, that is, when there is no more data in the central resource buffer).

NOTE: The CSI1/CCP2B receiver must also be configured to smart standby mode when the camera ISP is set to smart standby ([CCP2_SYSCONFIG](#) [13:12] MSTANDBY_MODE set to 0x2).

CSI2A and CSI2C receivers must also be configured to smart standby mode when the camera ISP is set to smart standby ([CSI2_SYSCONFIG](#)[13:12] MSTANDBY_MODE set to 0x2).

A standby request asserted to the PRCM does not necessarily lead to CAM_FCLK and CAM_ICLK being cut. The PRCM must also be set correctly for that purpose.

The clocks are cut, allowing a CAMERA power state change if:

- PRCM.CM_ICLKEN_CAM[0] EN_CAM = 0 and PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0
- PRCM.CM_FCLKEN_CAM[0] EN_CAM = 0, (PRCM.CM_ICLKEN_CAM[0] EN_CAM = 1, PRCM.CM_AUTOIDLE_CAM[0] = 1, and a domain transition is required at PRCM level)

See [Chapter 3, Power, Reset, and Clock Management](#), for further details.

6.3.1.3 Camera ISP Power Domain

The camera ISP belongs to the CAMERA power domain. For more information about the CAMERA power domain, see [Chapter 3, Power, Reset, and Clock Management](#).

6.3.1.4 Camera ISP Resets

6.3.1.4.1 Camera ISP Hardware Reset

Global reset of the camera ISP module is accomplished by activation of the CAM_RST signal in the CAMERA domain (for more information, see [Chapter 3, Power, Reset, and Clock Management](#)).

6.3.1.4.2 Camera ISP Software Reset

A global software reset can be accomplished by setting the camera ISP [ISP_SYSCONFIG \[1\] SOFT_RESET](#) bit to 1. Setting this bit enables active software reset functionality equivalent to hardware reset for the entire module, including CSI1/CCP2B, CSI2A, and CSI2C receivers.

NOTE: The CSI1/CCP2B receiver accepts a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset.

The CSI1/CCP2B receiver can be reset by writing [CCP2_SYSCONFIG \[1\] SOFT_RESET](#) bit to 1. The software can monitor the [CCP2_SYSSTATUS \[0\] RESET_DONE](#) status bit to wait for the completion of the reset procedure.

If after five reads, [CCP2_SYSSTATUS \[0\] RESET_DONE](#) still returns 0, it can be assumed that an error occurred during the reset stage.

The CSI2A and CSI2C receivers accept a general software reset, propagated through the hierarchy. This reset can be performed to initialize the module and has the same effect as a hardware reset.

The CSI2A and CSI2C receivers can be reset by writing [CSI2_SYSCONFIG \[1\] SOFT_RESET](#) bit to 1. The software can monitor the [CSI2_SYSSTATUS \[0\] RESET_DONE](#) status bit to wait for the completion of the reset procedure.

If after five reads, [CSI2_SYSSTATUS \[0\] RESET_DONE](#) still returns 0, it can be assumed that an error occurred during the reset stage.

6.3.2 Camera ISP Hardware Requests

6.3.2.1 Camera ISP Interrupt Requests

[Figure 6-52](#) shows the interrupt generation tree of the camera subsystem.

Figure 6-52. Camera ISP Interrupt Generation Tree

camisp-231

(1) x = 0 to 7

The camera ISP can generate two interrupts:

- CAM_IRQ0 is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_24.
- CAM_IRQ1 is an interrupt to the IVA2.2 subsystem interrupt controller. It is mapped on IVA2_IRQ[11].

Table 6-15 summarizes events that cause interrupts.

Table 6-15. Camera ISP Interrupts

Event	Mask	Description
ISP_IRQ0STATUS [31] HS_VS_IRQ	ISP_IRQ0ENABLE [31] HS_VS_IRQ	HS or VS synchronization event: triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen with the ISP_CTRL [15:14] SYNC_DETECT bit field. ⁽¹⁾
ISP_IRQ0STATUS [28] MMU_ERR_IRQ	ISP_IRQ0ENABLE [28] MMU_ERR_IRQ	MMU error

⁽¹⁾ This event is detected on the incoming HS/VS signals before the CCDC. Therefore, it cannot be used in BT656 mode.

Table 6-15. Camera ISP Interrupts (continued)

Event	Mask	Description
ISP_IRQ0STATUS [25] OVF_IRQ	ISP_IRQ0ENABLE [25] OVF_IRQ	Central-resource SBL overflow: triggered when one of the buffers in the central-resource SBL overflows
ISP_IRQ0STATUS [24] RSZ_DONE_IRQ	ISP_IRQ0ENABLE [24] RSZ_DONE_IRQ	RESIZER module. Resizer processing-done event: Triggered at the end of the frame when processing is complete for the current frame. It applies to one-shot and continuous modes.
ISP_IRQ0STATUS [21] CBUFF_IRQ	ISP_IRQ0ENABLE [24] CBUFF_IRQ	CBUFF module event. See CBUFF_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [20] PRV_DONE_IRQ	ISP_IRQ0ENABLE [20] PRV_DONE_IRQ	PREVIEW module: Processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [19] CCDC_LSC_PREFETCH_ERROR	ISP_IRQ0ENABLE [19] PRV_DONE_IRQ	CCDC module. The prefetch error indicates when the gain table was read too slowly from memory. When this event is pending, the module goes into transparent mode (output = input). Normal operation can be resumed at the start of the next frame after: 1) Clearing this event 2) Disabling the LSC module 3) Enabling it
ISP_IRQ0STATUS [18] CCDC_LSC_PREFETCH_COMPLETED	ISP_IRQ0ENABLE [18] CCDC_LSC_PREFETCH_COMPLETED	CCDC module. Indicates the current state of the prefetch buffer. Can be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It can be used to minimize buffer underflow risks.
ISP_IRQ0STATUS [17] CCDC_LSC_DONE	ISP_IRQ0ENABLE [17] CCDC_LSC_DONE	CCDC module. The event is triggered when the internal state of LSC toggles from BUSY to IDLE. This happens when the LSC module has completed processing the current frame.
ISP_IRQ0STATUS [16] HIST_DONE_IRQ	ISP_IRQ0ENABLE [16] HIST_DONE_IRQ	HIST module. Processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [13] H3A_AWB_DONE_IRQ	ISP_IRQ0ENABLE [13] H3A_AWB_DONE_IRQ	H3A module. Auto exposure and auto white balance processing done event: Triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [12] H3A_AF_DONE_IRQ	ISP_IRQ0ENABLE [12] H3A_AF_DONE_IRQ	H3A module. Autofocus processing-done event: triggered at the end of the frame when processing is complete for the current frame
ISP_IRQ0STATUS [11] CCDC_ERR_IRQ	ISP_IRQ0ENABLE [11] CCDC_ERR_IRQ	CCDC module. Faulty-pixel correction error: Faulty-pixel correction memory underflow. Triggered to signal an error in the faulty-pixel correction logic. The hardware did not have time to read the faulty-pixel LUT from external memory in time.
ISP_IRQ0STATUS [10] CCDC_VD2_IRQ	ISP_IRQ0ENABLE [10] CCDC_VD2_IRQ	CCDC module. Programmable event 2: triggered by the falling edge on the cam_wen signal. This event is not programmable.
ISP_IRQ0STATUS [9] CCDC_VD1_IRQ	ISP_IRQ0ENABLE [9] CCDC_VD1_IRQ	CCDC module. Programmable event 1: triggered after a programmable number of horizontal lines is received after a VS pulse
ISP_IRQ0STATUS [8] CCDC_VD0_IRQ	ISP_IRQ0ENABLE [8] CCDC_VD0_IRQ	CCDC module. Programmable event 0: triggered after a programmable number of horizontal lines is received after a VS pulse
ISP_IRQ0STATUS [7] CSI1_LC3_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC3_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC23_IRQSTATUS to know which interrupt it is.

Table 6-15. Camera ISP Interrupts (continued)

Event	Mask	Description
ISP_IRQ0STATUS [6] CSI1_LC2_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC2_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC23_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [5] CSI1_LC1_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC1_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC01_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [4] CSI1_LC0_IRQ	ISP_IRQ0ENABLE [4] CSI1_LC0_IRQ	CSI1/CCP2B receiver module event. See CCP2_LC01_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [3] CSI1_LCM_IRQ	ISP_IRQ0ENABLE [3] CSI1_LCM_IRQ	CSI1 receiver module event on memory channel.
ISP_IRQ0STATUS [1] CSI2C_IRQ	ISP_IRQ0ENABLE [1] CSI2C_IRQ	CSI2C receiver module event. See CSI2_IRQSTATUS to know which interrupt it is.
ISP_IRQ0STATUS [0] CSI2A_IRQ	ISP_IRQ0ENABLE [0] CSI2A_IRQ	CSI2A receiver module event. See CSI2_IRQSTATUS to know which interrupt it is.

NOTE: n is equal to 0 or 1.

l is equal to 01 or 23.

Table 6-16 summarizes the CBUFF interrupts.

Table 6-16. Camera ISP CBUFF Interrupt Details

Event	Mask	Description
CBUFF_IRQSTATUS [5] IRQ_CBUFF1_OVR	CBUFF_IRQENABLE [5] IRQ_CBUFF1_OVR	Buffer overflow event: The generation of this event depends on the CBUFFx_CTRL.ALLOW_NW_EQ_CR flag and the circular buffer mode (read or write). This event indicates a bandwidth mismatch between data producer and data consumer. When it occurs, CBUFFx does NOT go into error state. However, the data in the physical buffer is very likely to be corrupted.
CBUFF_IRQSTATUS [4] IRQ_CBUFF1_INVALID	CBUFF_IRQENABLE [4] IRQ_CBUFF1_INVALID	<p>Invalid access:</p> <ul style="list-style-type: none"> • Camera controller writes the virtual space of CBUFFx in read mode. • Camera controller reads the virtual space of CBUFFx in write mode. • HW writes the virtual space of circular buffer x outside the CW or NW window in write mode. • HW reads the virtual space of circular buffer x outside the CW or NW window in read mode. • NW full • CPU write the DONE bit when physical buffers are not ready for the CPU. <p>This event indicates a wrong configuration of the circular buffer, the camera ISP, or bogus software. When it occurs, CBUFFx goes into an error state. In this state all accesses to the virtual space of CBUFFx are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory.</p> <p>The error state can be left by disabling the CBUFFx and reenabling it. Before doing so, the SW must ensure that there are no more outstanding requests to the virtual space of CBUFFx.</p>

Table 6-16. Camera ISP CBUFF Interrupt Details (continued)

Event	Mask	Description
CBUFF_IRQSTATUS [3] IRQ_CBUFF1_READY	CBUFF_IRQENABLE [3] IRQ_CBUFF1_READY	The CPUW1 physical buffer is ready to be accessed by the CPU.
CBUFF_IRQSTATUS [2] IRQ_CBUFF0_OVR	CBUFF_IRQENABLE [2] IRQ_CBUFF0_OVR	Buffer overflow event. See description of IRQ_CBUFF1_OVR event.
CBUFF_IRQSTATUS [1] IRQ_CBUFF0_INVALID	CBUFF_IRQENABLE [1] IRQ_CBUFF0_INVALID	Invalid access. See description of IRQ_CBUFF1_INVALID event.
CBUFF_IRQSTATUS [0] IRQ_CBUFF0_READY	CBUFF_IRQENABLE [0] IRQ_CBUFF0_READY	The CPUW1 physical buffer is ready to be accessed by the CPU

Table 6-17 describes the CSI1/CCP2B receiver interrupts.

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details

Event	Mask	Description
CCP2_LC01_IRQSTATUS[27] LC1_FS_IRQ	CCP2_LC01_IRQENABLE[27] LC1_FS_IRQ	Frame-start synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[26] LC1_LE_IRQ	CCP2_LC01_IRQENABLE[26] LC1_LE_IRQ	Line-end synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[25] LC1_LS_IRQ	CCP2_LC01_IRQENABLE[25] LC1_LS_IRQ	Line-start synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[24] LC1_FE_IRQ	CCP2_LC01_IRQENABLE[24] LC1_FE_IRQ	Frame-end synchronization code detection for logical channel 1: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS[23] LC1_COUNT_IRQ	CCP2_LC01_IRQENABLE[23] LC1_COUNT_IRQ	Frame counter reached for logical channel 1: This interrupt is triggered when the frame counter has reached its programmable target value.
CCP2_LC01_IRQSTATUS[21] LC1_FIFO_OVF_IRQ	CCP2_LC01_IRQENABLE[21] LC1_FIFO_OVF_IRQ	FIFO overflow error for logical channel 1: This interrupt is triggered upon detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC01_IRQSTATUS[20] LC1_CRC_IRQ	CCP2_LC01_IRQENABLE[20] LC1_CRC_IRQ	CRC error for logical channel 1: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums. This interrupt does not apply to the MIPI CSI1 compatible mode.
CCP2_LC01_IRQSTATUS[19] LC1_FSP_IRQ	CCP2_LC01_IRQENABLE[19] LC1_FSP_IRQ	False synchronization code protection error for logical channel 1: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC01_IRQSTATUS[18] LC1_FW_IRQ	CCP2_LC01_IRQENABLE[18] LC1_FW_IRQ	Frame-width error for logical channel 1: This interrupt is generated if the frame width constraints associated to the current data type is not respected.
CCP2_LC01_IRQSTATUS[17] LC1_FSC_IRQ	CCP2_LC01_IRQENABLE[17] LC1_FSC_IRQ	False synchronization code error for logical channel 1: This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state-machine.

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC01_IRQSTATUS [16] LC1_SSC_IRQ	CCP2_LC01_IRQENABLE [16] LC1_SSC_IRQ	Shifted synchronization code error for logical channel 1: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽¹⁾
CCP2_LC01_IRQSTATUS [11] LC0_FS_IRQ	CCP2_LC01_IRQENABLE [11] LC0_FS_IRQ	Frame-start synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [10] LC0_LE_IRQ	CCP2_LC01_IRQENABLE [10] LC0_LE_IRQ	Line-end synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [9] LC0_LS_IRQ	CCP2_LC01_IRQENABLE [9] LC0_LS_IRQ	Line-start synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [8] LC0_FE_IRQ	CCP2_LC01_IRQENABLE [8] LC0_FE_IRQ	Frame-end synchronization code detection for logical channel 0: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [7] LC0_COUNT_IRQ	CCP2_LC01_IRQENABLE [7] LC0_COUNT_IRQ	Frame counter reached for logical channel 0: This interrupt is triggered on the frame counter reached into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [5] LC0_FIFO_OVF_IRQ	CCP2_LC01_IRQENABLE [5] LC0_FIFO_OVF_IRQ	FIFO overflow error for logical channel 0: This interrupt is triggered on the detection of a FIFO overflow error.
CCP2_LC01_IRQSTATUS [4] LC0_CRC_IRQ	CCP2_LC01_IRQENABLE [4] LC0_CRC_IRQ	CRC error This interrupt is triggered on the detection of a CRC error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [3] LC0_FSP_IRQ	CCP2_LC01_IRQENABLE [3] LC0_FSP_IRQ	False synchronization code protection error for logical channel 0: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC01_IRQSTATUS [2] LC0_FW_IRQ	CCP2_LC01_IRQENABLE [2] LC0_FW_IRQ	Frame-width error for logical channel 0: This interrupt is triggered on the detection of a frame-width error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [1] LC0_FSC_IRQ	CCP2_LC01_IRQENABLE [1] LC0_FSC_IRQ	False synchronization code error for logical channel 0: This interrupt is triggered on the detection of a false synchronization code error into the CCP2 data stream.
CCP2_LC01_IRQSTATUS [0] LC0_SSC_IRQ	CCP2_LC01_IRQENABLE [0] LC0_SSC_IRQ	Shifted synchronization code error for logical channel 0: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽²⁾
CCP2_LC23_IRQSTATUS [27] LC3_FS_IRQ	CCP2_LC23_IRQENABLE [27] LC3_FS_IRQ	Frame-start synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream

⁽¹⁾ This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1).

⁽²⁾ This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1).

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC23_IRQSTATUS [26] LC3_LE_IRQ	CCP2_LC23_IRQENABLE [26] LC3_LE_IRQ	Line-end synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [25] LC3_LS_IRQ	CCP2_LC23_IRQENABLE [25] LC3_LS_IRQ	Line-start synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [24] LC3_FE_IRQ	CCP2_LC23_IRQENABLE [24] LC3_FE_IRQ	Frame-end synchronization code detection for logical channel 3: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [23] LC3_COUNT_IRQ	CCP2_LC23_IRQENABLE [23] LC3_COUNT_IRQ	Frame counter reached for logical channel 3: This interrupt is triggered when the frame counter has reached its programmable target value.
CCP2_LC23_IRQSTATUS [21] LC3_FIFO_OVF_IRQ	CCP2_LC23_IRQENABLE [21] LC3_FIFO_OVF_IRQ	FIFO overflow error error for logical channel 3: This interrupt is triggered upon detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates.
CCP2_LC23_IRQSTATUS [20] LC3_CRC_IRQ	CCP2_LC23_IRQENABLE [20] LC3_CRC_IRQ	CRC error for logical channel 3: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums. This interrupt does not apply to the MIPI CSI1 compatible mode.
CCP2_LC23_IRQSTATUS [19] LC3_FSP_IRQ	CCP2_LC23_IRQENABLE [19] LC3_FSP_IRQ	False synchronization code protection error for logical channel 3: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC23_IRQSTATUS [18] LC3_FW_IRQ	CCP2_LC23_IRQENABLE [18] LC3_FW_IRQ	Frame-width error for logical channel 3: This interrupt is generated if the frame width constraints associated to the current data type is not respected.
CCP2_LC23_IRQSTATUS [17] LC3_FSC_IRQ	CCP2_LC23_IRQENABLE [17] LC3_FSC_IRQ	False synchronization code error for logical channel 3: This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state machine.
CCP2_LC23_IRQSTATUS [16] LC3_SSC_IRQ	CCP2_LC23_IRQENABLE [16] LC3_SSC_IRQ	Shifted synchronization code error for logical channel 3: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽³⁾
CCP2_LC23_IRQSTATUS [11] LC2_FS_IRQ	CCP2_LC23_IRQENABLE [11] LC2_FS_IRQ	Frame-start synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [10] LC2_LE_IRQ	CCP2_LC23_IRQENABLE [10] LC2_LE_IRQ	Line-end synchronization code detection detection for logical channel 2: This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream.

⁽³⁾ This error can be triggered if the complex I/O cell is used in parallel output mode (CCP_CTRL[2]IO_OUT_SEL=1).

Table 6-17. Camera ISP CSI1/CCP2B Receiver Interrupt Details (continued)

Event	Mask	Description
CCP2_LC23_IRQSTATUS [9] LC2_LS_IRQ	CCP2_LC23_IRQENABLE [9] LC2_LS_IRQ	Line-start synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a line-start synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [8] LC2_FE_IRQ	CCP2_LC23_IRQENABLE [8] LC2_FE_IRQ	Frame-end synchronization code detection for logical channel 2: This interrupt is triggered on the detection of a frame-end synchronization code into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [7] LC2_COUNT_IRQ	CCP2_LC23_IRQENABLE [7] LC2_COUNT_IRQ	Frame counter reached for logical channel 2: This interrupt is triggered on the frame counter reached into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [5] LC2_FIFO_OVF_IRQ	CCP2_LC23_IRQENABLE [5] LC2_FIFO_OVF_IRQ	FIFO overflow error for logical channel 2: This interrupt is triggered on the detection of a FIFO overflow error.
CCP2_LC23_IRQSTATUS [4] LC2_CRC_IRQ	CCP2_LC23_IRQENABLE [4] LC2_CRC_IRQ	CRC error for logical channel 2: This interrupt is triggered on the detection of a CRC error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [3] LC2_FSP_IRQ	CCP2_LC23_IRQENABLE [3] LC2_FSP_IRQ	False synchronization code protection error for logical channel 2: This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bit stream.
CCP2_LC23_IRQSTATUS [2] LC2_FW_IRQ	CCP2_LC23_IRQENABLE [2] LC2_FW_IRQ	Frame-width error for logical channel 2: This interrupt is triggered on the detection of a frame-width error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [1] LC2_FSC_IRQ	CCP2_LC23_IRQENABLE [1] LC2_FSC_IRQ	False synchronization code error error for logical channel 2: This interrupt is triggered on the detection of a false synchronization code error into the CCP2 data stream.
CCP2_LC23_IRQSTATUS [0] LC2_SSC_IRQ	CCP2_LC23_IRQENABLE [0] LC2_SSC_IRQ	Shifted synchronization code error for logical channel 2: This interrupt is triggered if LEC or FEC are not aligned on a 32-bit boundary. This state is shown in the CCP2 receiver finite state-machine. The shifted synchronization code error is highlighted in the CCP2 receiver finite state-machine. ⁽⁴⁾
CCP2_LCM_IRQSTATUS [1] LCM_OCPERROR	CCP2_LCM_IRQENABLE [1] LCM_OCPERROR	An OCP error occurred on the master read port. This interrupt is triggered on the detection of an OCP error on the master read port.
CCP2_LCM_IRQSTATUS [0] LCM_EOF	CCP2_LCM_IRQENABLE [0] LCM_EOF	Memory read channel end of frame: This interrupt is triggered when a frame has been completely read from memory.

⁽⁴⁾ This error can be triggered if the complex I/O cell is used in parallel output mode ([CCP_CTRL](#)[2]IO_OUT_SEL=1).

[Table 6-18](#) shows CSI2A and CSI2C receivers event generation through the CSI2 interrupt status and interrupt enable registers.

Table 6-18. Camera ISP CSI2A and CSI2C Receivers Event Generation

Event	Mask	Description
CSI2_IRQSTATUS [0] CONTEXT0	CSI2_IRQENABLE [0] CONTEXT0	At least one interrupt event enabled from Context 0 occurred (see Table 6-20).
CSI2_IRQSTATUS [1] CONTEXT1	CSI2_IRQENABLE [1] CONTEXT1	At least one interrupt event enabled from Context 1 occurred (see Table 6-20).
CSI2_IRQSTATUS [2] CONTEXT2	CSI2_IRQENABLE [2] CONTEXT2	At least one interrupt event enabled from Context 1 occurred (see Table 6-20).
CSI2_IRQSTATUS [3] CONTEXT3	CSI2_IRQENABLE [3] CONTEXT3	At least one interrupt event enabled from Context 3 occurred (see Table 6-20).

Table 6-18. Camera ISP CSI2A and CSI2C Receivers Event Generation (continued)

Event	Mask	Description
CSI2_IRQSTATUS[4] CONTEXT4	CSI2_IRQENABLE[4] CONTEXT4	At least one interrupt event enabled from Context 4 occurred (see Table 6-20).
CSI2_IRQSTATUS[5] CONTEXT5	CSI2_IRQENABLE[5] CONTEXT5	At least one interrupt event enabled from Context 5 occurred (see Table 6-20).
CSI2_IRQSTATUS[6] CONTEXT6	CSI2_IRQENABLE[6] CONTEXT6	At least one interrupt event enabled from Context 6 occurred (see Table 6-20).
CSI2_IRQSTATUS[7] CONTEXT6	CSI2_IRQENABLE[7] CONTEXT7	At least one interrupt event enabled from Context 7 occurred (see Table 6-20).
CSI2_IRQSTATUS[8] FIFO_OVF_IRQ	CSI2_IRQENABLE[8] FIFO_OVF_IRQ	FIFO overflow error: This interrupt is triggered on detection of a FIFO overflow. An overflow can occur if there is a mismatch between the data input and output rates. A reset of the module is required to restart correctly.
CSI2_IRQSTATUS[9] PHY_ERR_IRQ	CSI2_IRQENABLE[9] PHT_ERR_IRQ	Error signaling from PHY: This interrupt is triggered when any error is received from the PHY (events are defined in CSI2_COMPLEXIO1_IRQSTATUS [see Table 6-19]).
CSI2_IRQSTATUS[11] ECC_NO_CORRECTION_IRQ	CSI2_IRQENABLE[11] ECC_NO_CORRECTION_IRQ	ECC was not used to correct the header because the error is larger than 1 bit (short and long packets).
CSI2_IRQSTATUS[12] ECC_CORRECTION_IRQ	CSI2_IRQENABLE[12] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (short packet only).
CSI2_IRQSTATUS[13] SHORT_PACKET_IRQ	CSI2_IRQENABLE[13] SHORT_PACKET_IRQ	Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types between 0x8 and 0xF are considered).
CSI2_IRQSTATUS[14] OCP_ERR_IRQ	CSI2_IRQENABLE[14] OCP_ERR_IRQ	OCP error

[Table 6-19](#) shows CSI2A and CSI2C receiver event generation interrupt status and interrupt enable registers receiving signals from the associated PHY.

Table 6-19. Camera ISP CSI2A and CSI2C Receiver Event Generation from PHY

Event	Mask	Description
CSI2_COMPLEXIO1_IRQSTATUS[0] ERRSOTHS1	CSI2_COMPLEXIO1_IRQENABLE[0] ERRSOTHS1	Start of transmission error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[1] ERRSOTHS2	CSI2_COMPLEXIO1_IRQENABLE[1] ERRSOTHS2	Start of transmission error for lane 2
CSI2_COMPLEXIO1_IRQSTATUS[2] ERRSOTHS3	CSI2_COMPLEXIO1_IRQENABLE[2] ERRSOTHS3	Start of transmission error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[5] ERRSOTSYNCHS1	CSI2_COMPLEXIO1_IRQENABLE[5] ERRSOTSYNCHS1	Start of transmission sync error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[6] ERRSOTSYNCHS2	CSI2_COMPLEXIO1_IRQENABLE[6] ERRSOTSYNCHS2	Start of transmission sync error for lane 2
CSI2_COMPLEXIO1_IRQSTATUS[7] ERRSOTSYNCHS3	CSI2_COMPLEXIO1_IRQENABLE[7] ERRSOTSYNCHS3	Start of transmission sync error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[10] ERRESC1	CSI2_COMPLEXIO1_IRQENABLE[10] ERRESC1	Escape entry error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[11] ERRESC2	CSI2_COMPLEXIO1_IRQENABLE[11] ERRESC2	Escape entry error for lane 2
CSI2_COMPLEXIO1_IRQSTATUS[12] ERRESC3	CSI2_COMPLEXIO1_IRQENABLE[12] ERRESC3	Escape entry error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[15] ERRCONTROL1	CSI2_COMPLEXIO1_IRQENABLE[15] ERRCONTROL1	Control error for lane 1
CSI2_COMPLEXIO1_IRQSTATUS[16] ERRCONTROL2	CSI2_COMPLEXIO1_IRQENABLE[16] ERRCONTROL2	Control error for lane 2

Table 6-19. Camera ISP CSI2A and CSI2C Receiver Event Generation from PHY (continued)

Event	Mask	Description
CSI2_COMPLEXIO1_IRQSTATUS[17] ERRCONTROL3	CSI2_COMPLEXIO1_IRQENABLE[17] ERRCONTROL3	Control error for lane 3
CSI2_COMPLEXIO1_IRQSTATUS[20] STATEULPM1	CSI2_COMPLEXIO1_IRQENABLE[20] STATEULPM1	Lane 1 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[21] STATEULPM2	CSI2_COMPLEXIO1_IRQENABLE[21] STATEULPM2	Lane 2 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[22] STATEULPM3	CSI2_COMPLEXIO1_IRQENABLE[22] STATEULPM3	Lane 3 in ULPM
CSI2_COMPLEXIO1_IRQSTATUS[25] STATEALLULPMENTER	CSI2_COMPLEXIO1_IRQENABLE[25] STATEALLULPMENTER	All active lanes are entering in ULPM.
CSI2_COMPLEXIO1_IRQSTATUS[26] STATEALLULPMEXIT	CSI2_COMPLEXIO1_IRQENABLE[26] STATEALLULPMEXIT	At least one active lane exited the ULPM.

As the CSI2A and CSI2C receivers supports eight contexts, the [CSI2_CTX_IRQSTATUS](#) and [CSI2_CTX_IRQENABLE](#) registers are present eight times (one time per context).

The events are generated only for the enabled context(s). [Table 6-20](#) describes the CSI2A and CSI2C receiver event generation through the CTx interrupt status and interrupt enable registers.

Table 6-20. Camera ISP CSI2A and CSI2C CTx Receiver Event Generation

Event	Mask	Description
CSI2_CTX_IRQSTATUS[0] FS_IRQ	CSI2_CTX_IRQENABLE[0] FS_IRQ	Frame start: This interrupt is triggered on the detection of a frame-start synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[1] FE_IRQ	CSI2_CTX_IRQENABLE[1] FE_IRQ	Frame end: This interrupt is triggered on the detection of a frame-end synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[2] LS_IRQ	CSI2_CTX_IRQENABLE[2] LS_IRQ	Line start: This interrupt is triggered on the detection of a line-start synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[3] LE_IRQ	CSI2_CTX_IRQENABLE[3] LE_IRQ	Line end: This interrupt is triggered on the detection of a line-end synchronization code into the CSI2 data stream.
CSI2_CTX_IRQSTATUS[5] CS_IRQ	CSI2_CTX_IRQENABLE[5] CS_IRQ	CS error: This interrupt is triggered upon detection of a mismatch between the transmitter and receiver checksums (payload).
CSI2_CTX_IRQSTATUS[6] FRAME_NUMBER_IRQ	CSI2_CTX_IRQENABLE[6] FRAME_NUMBER_IRQ	Frame counter reached: This interrupt is triggered when the frame counter reaches its programmable target value.
CSI2_CTX_IRQSTATUS[7] LINE_NUMBER_IRQ	CSI2_CTX_IRQENABLE[7] LINE_NUMBER_IRQ	Line number reached: The programmable line number is received. The modulo feature can be selected (CSI2_CTX_CTRL1.LINE_MODULO). When selected, the interrupt is generated for each line number multiple of the programmed line number (CSI2_CTX_CTRL3.LINE_NUMBER); otherwise, the interrupt is generated only for the line number.
CSI2_CTX_IRQSTATUS[8] ECC_CORRECTION_IRQ	CSI2_CTX_IRQENABLE[8] ECC_CORRECTION_IRQ	ECC was used to correct a 1-bit error (long packets only).

6.4 Camera ISP Functional Description

6.4.1 Camera ISP Block Diagram

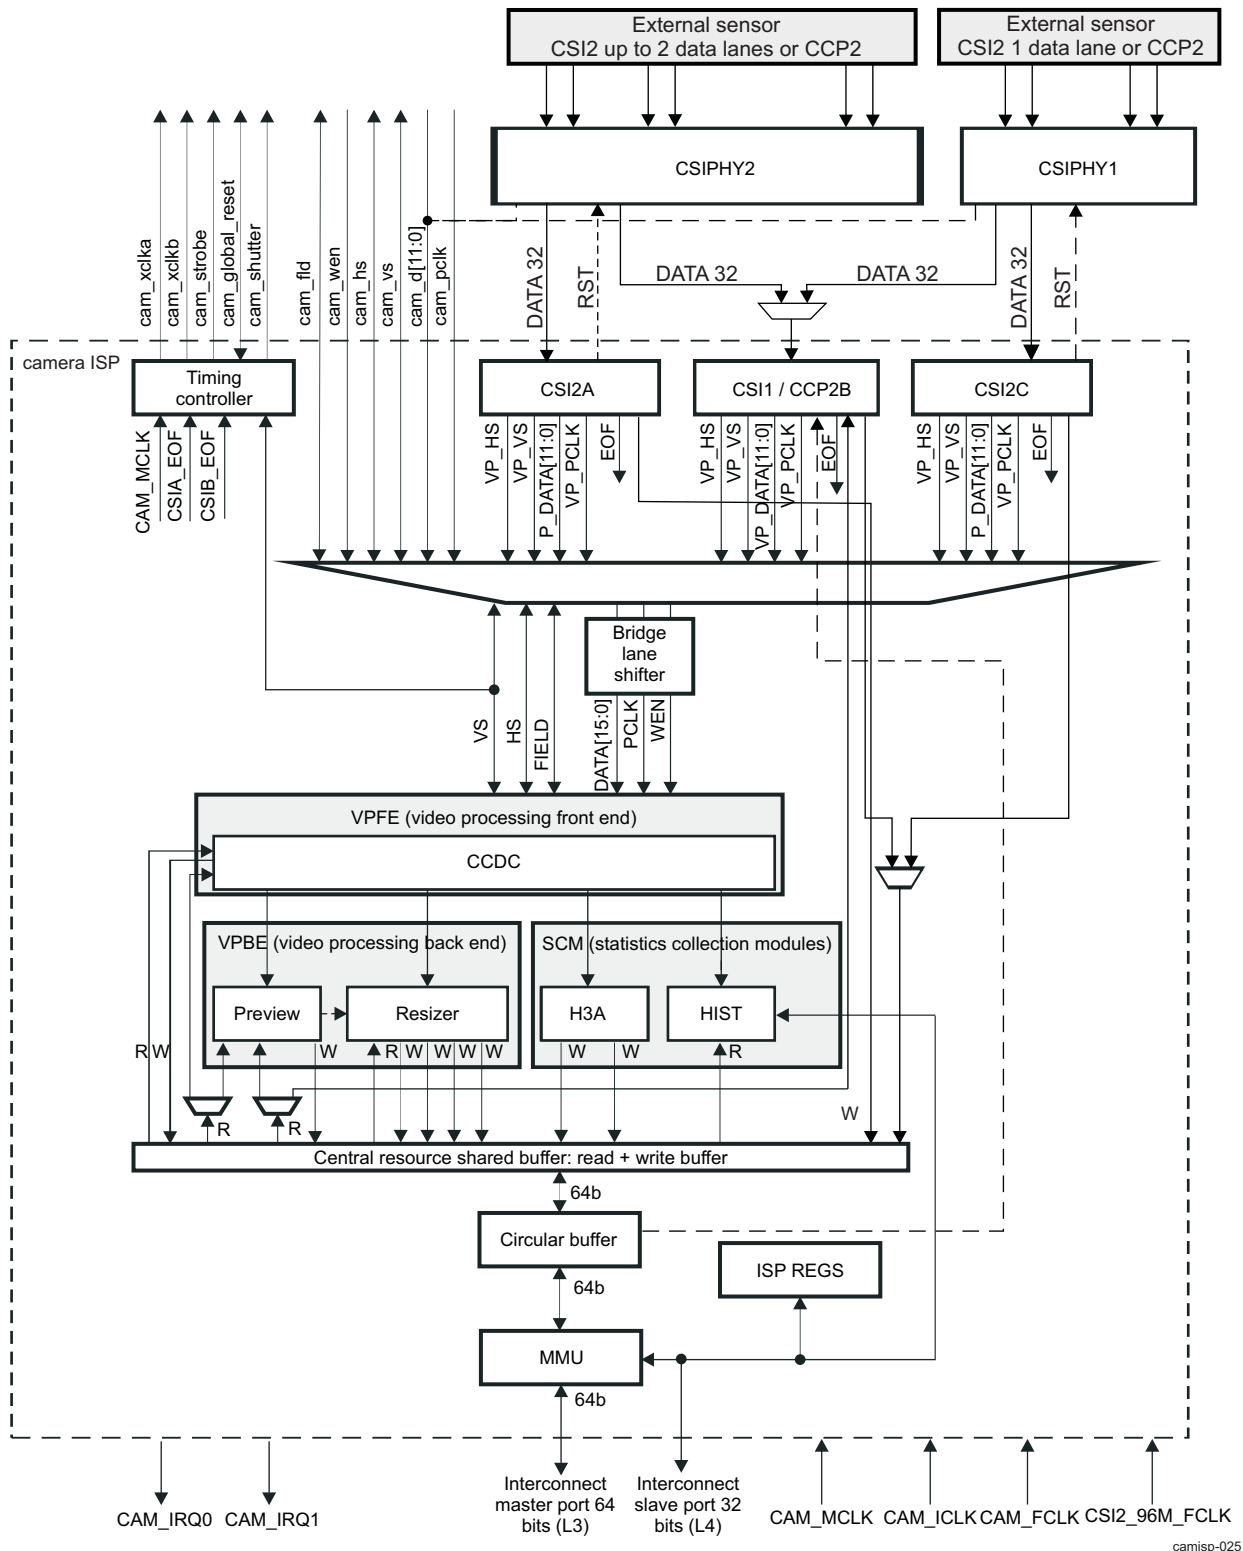

[Figure 6-53](#) is the camera ISP top-level block diagram. The camera ISP supports two simultaneous pixel flows, but only one of them can use the Video processing hardware at a time.

See [Section 6.2.3](#) for connectivity configurations and limitations details.

The camera ISP master port is connected to the L3 interconnect, and the slave port is connected to the L4 interconnect (from the camera ISP point of view, commands are output from the camera ISP to the L3 and data are input/output. From the camera ISP point of view, commands are input from the L4 to the camera ISP and data are input/output).

[Figure 6-53](#) shows the camera ISP block diagram.

Figure 6-53. Camera ISP Block Diagram

The camera ISP module comprises the following blocks:

- Timing control: Includes a timing generator and a control-signal generator:
 - The timing generator allows the generation of two clocks that can be used by the external image sensors.

- The control-signal generator allows the generation of signals for strobe flash, mechanical shutter, and global reset.
- Three CSI receivers (one CCP2/MIPI CSI1 and two MIPI CSI2): The CSI receivers communicate with a serial camera through the PHY's and transfers received data to memory or to the Video processing hardware.
- Bridge-lane shifter:
 - The data-lane shifter gives flexibility to the parallel camera connection and permits dynamic reduction of pixel data.
 - The bridge allows higher transfer rates when data is captured from the parallel interface and sent to memory.
- Video-processing front end (VPFE): Comprises the CCDC. This module provides the camera ISP with a powerful and flexible front end interface. It directly affects the input image data:
 - The CCDC provides an interface to image sensors and digital video sources and processes image data.
- Video-processing back end (VPBE): Comprises preview and resizer modules:
 - The preview module is a parameterized hardwired image-processing block whose image-processing functions can be customized for each sensor type to realize good image quality and video frame rates for digital still camera preview displays and video-recording modes.
 - The resizer module provides a means of sizing the input image data to the desired display or video-encoding resolution. Zoom is limited to 4x in both vertical and horizontal directions for each pass. After one (on-the-fly) upscaling pass, the image can be sent to memory and then resent through the resizer.
- Statistics-collection modules (SCM): H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems:
 - The hardware 3A module supports the control loops for AF, AWB, and AE by collecting metrics about RAW image data from the CCDC.
 - The histogram module bins input color pixels, depending on the amplitude, and provide statistics required to implement various 3A (AE/AF/AWB) algorithms and tune the final image/video output. The histogram module can operate on RAW image data from CCDC or memory.
- Central-resource shared buffer logic (CRSBL): Buffers and schedules memory accesses requested by the camera modules
- Circular buffer: Avoids storage of full image frames in the memory when the data must be post and/or preprocessed by software.
- MMU: Performs virtual-to-physical address translation between its interconnect slave and interconnect master access ports

6.4.1.1 Camera ISP Possible Data Paths Inside the module

Data paths inside the camera ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG,...).

[Table 6-21](#) lists the modules used for the different data types. The formats described in the columns are the formats at the inputs of the CCDC. It is the internal parallel format.

Table 6-21. Camera ISP Allowed Data Flows for Hardware

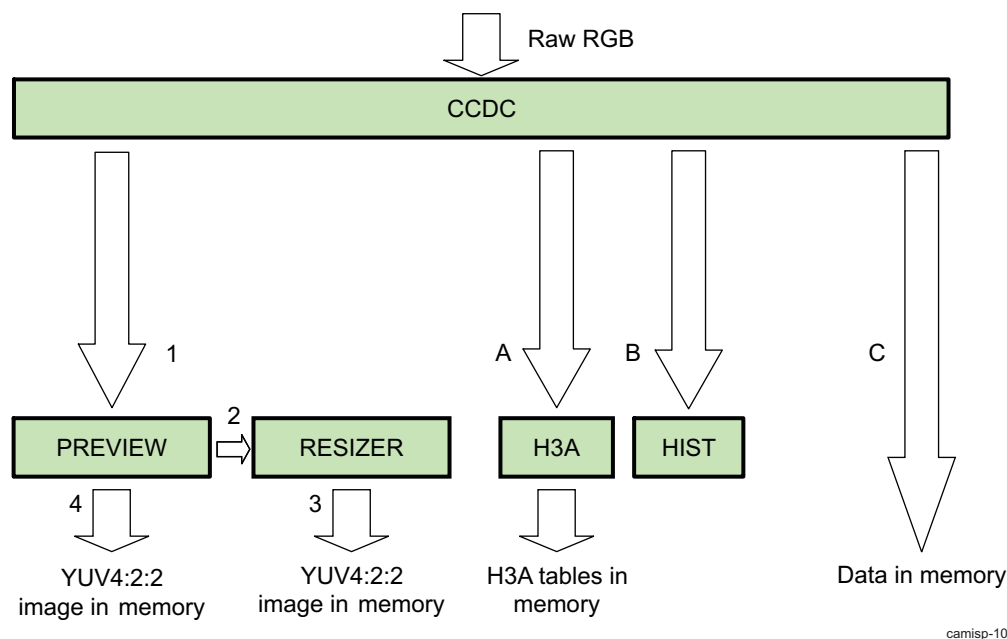

Module	8/10 bit RAW from sensor	11/12 bit RAW from sensor	BT 656 8/10 bit	YUV 8/10 bit
CCDC Bridge lane shifter				X
CCDC BT 656 decoder			x	
CCDC DC subtract	x	x	x	x
CCDC Optical Black clamp	x	x		
CCDC Faulty pixel correction	x	x		
CCDC Data formatter	x			

Table 6-21. Camera ISP Allowed Data Flows for Hardware (continued)

Module	8/10 bit RAW from sensor	11/12 bit RAW from sensor	BT 656 8/10 bit	YUV 8/10 bit
CCDC Preview, H3A, Histogram data paths	x			
CCDC Output formatter	x	x	x	x
CCDC Low pass filter	x	x		
CCDC Culling	x	x	x	x
CCDC Alaw	x	x		
CCDC Resizer Datapath			x	x
CCDC Memory Datapath	x	x	x	x
CCDC Shading compensator	x			
Preview	x			
Resizer	x		x	x
H3A	x			
Histogram	x			

6.4.1.1.1 Camera ISP RGB RAW Data

Figure 6-54 shows the data path of images in RAW format.

Figure 6-54. Camera ISP/Data Path/RAW RGB Images

RAW data are processed through the CCDC module and are directly pipelined to the preview engine(1). Another way is to output directly from the CCDC to memory (C) In the preview block; the format is converted from RAW data to YUV4:2:2. The data can be output to memory (4) or pipelined to the resizer (2). The rescaled YUV4:2:2 image is finally stored in memory (3).

In parallel, processed data in the CCDC are used by the H3A module (A), which writes tables of statistics in memory, and by the HIST module (B). The results of the HIST modules are stored in status registers in the HIST module.

NOTE:

- This data path is correct for RAW10 data.
- The data path for RAW8 data is similar to that for RAW10, except that the autofocus module in the H3A does not support RAW8.
- RAW11 data must be sent directly to memory (C).
- RAW12 data must be sent to memory (C) or pixel dynamic must be reduced RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.
- RAW14 data must be sent to memory (C) or pixel dynamic must be reduced to RAW8 or RAW10 by the bridge-lane shifter module, before the CCDC.

6.4.1.1.2 Camera ISP YUV4:2:2 Data

Figure 6-55 shows the data path of images in YUV4:2:2 format.

Figure 6-55. Camera ISP / Data Path/YUV4:2:2 Images

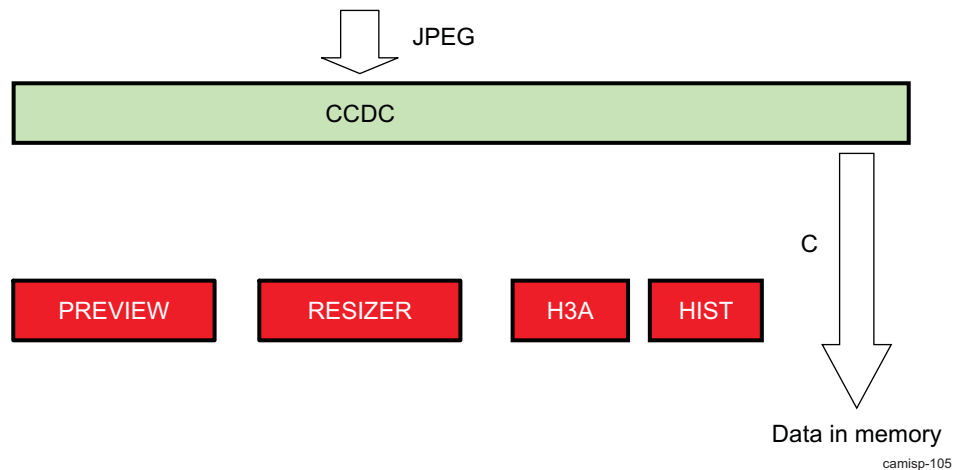

camisp-104

When the sensor-output format is YUV4:2:2, the CCDC block is directly pipelined to the resizer (1) or output directly to the memory (C). The rescaled YUV4:2:2 images are finally stored in memory (2).

The modules in red in Figure 6-55 are not used when the format is YUV4:2:2.

6.4.1.1.3 JPEG Data

Figure 6-56 shows the data path of images in JPEG format.

Figure 6-56. Camera ISP/Data Path/JPEG Images

When the sensor output format is JPEG, the CCDC block is directly output to the memory (C). The modules in red in [Figure 6-56](#) are not used when the format is JPEG.

6.4.2 Camera ISP CSI1/CCP2B Receiver

The CSI1 / CCP2B receiver is compatible with the CCP2 specification and the MIPI CSI1 specification.

6.4.2.1 Camera ISP CSI1/CCP2B Receiver Features

The CSI1/CCP2B receiver features are listed below:

- Image from sensor
 - Transfer of pixels and data received by the associated PHY to system memory or to the Video processing hardware
 - Unidirectional data link
 - 1D and 2D addressing mode
 - False synchronization code protection
 - Ping-pong mechanism for double-buffering
 - Support of RGB, RAW, YUV, and JPEG formats
 - Support of DPCM compression and decompression
- Image read from memory
 - RAW formats supported

6.4.2.2 Camera ISP CSI1/CCP2B Receiver Functional Description

6.4.2.2.1 Camera ISP CSI1/CCP2B Overview

[Figure 6-57](#) is the CSI1/CCP2B receiver top-level block diagram. The CSI1/CCP2B receiver takes serial data from a CSI1/CCP2B-compatible image sensor through the selected PHY, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it to the Video processing hardware or to memory.

The CSI1/CCP2B receiver video-port interface is connected to the Video processing hardware.

Figure 6-57. Camera ISP CSI1/CCP2B Receiver Block Diagram

6.4.2.2.2 Camera ISP CSI1/CCP2B Associated PHY

The CSI1/CCP2B receiver's selected PHY is controlled by 2 bits of the CCP2_CTRL register:

- The CCP2_CTRL[2] IO_OUT_SEL bit selects the output mode of the PHY which must be set to 1 for parallel.

CAUTION

CCP2_CTRL[2] IO_OUT_SEL bit must be set to 1(parallel mode) after reset and at normal work flow. If not set, it could cause ISP functional stall.

- The CCP2_CTRL[10] INV bit selects the clock edge used to sample data:
 - If CCP2_CTRL[10] INV = 0x0, use the rising edge.
 - If CCP2_CTRL[10] INV = 0x1, use the falling edge.

The CSI1/CCP2B receiver associated configured PHY is controlled by a SCM registers: SCM.CONTROL_CAMERA_PHY_CTRL

- SCM.CONTROL_CAMERA_PHY_CTRL[4] CSI1_RX_sel:
 - CSIPHY1 data is sent to ISP CSI1/ CCP2B if set to 0
 - CSIPHY2 data is sent to ISP CSI1/ CCP2B if set to 1

For information about initializing the CSIPHY associated with CSI1/CCP2B, see Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver.

See Section 6.2.3 for further connectivity schema details.

6.4.2.2.3 Camera ISP CSI1/CCP2B Physical Layer

The CSI1/CCP2B serial interface is a unidirectional differential serial interface with two options for the physical layer: data/clock or data/strobe signals. The physical layer of the CSI1/CCP2B is based on SubLVDS signaling.

CCP2B defines three classes for data transfer between the transmitter and the receiver. Table 6-22 summarizes the CSI1/CCP2B classifications. Class 1 and class 2 do not apply to the MIPI CSI1-compatible mode.

Table 6-22. Camera ISP CSI1/CCP2B Transmitter Classification

Class	Data Transfer Capacity	Signaling Method
Class 0 (CSI1/CCP2)	208 Mbps	Data/clock
Class 1 (CCP2 only)	208 Mbps to 416 Mbps	Data/strobe

Table 6-22. Camera ISP CSI1/CCP2B Transmitter Classification (continued)

Class	Data Transfer Capacity	Signaling Method
Class 2 (CCP2 only)	416 Mbps to 650 Mbps	Data/strobe

6.4.2.2.3.1 Camera ISP CSI1/CCP2B Data/Clock Signaling

Data/clock signaling consists of two parallel signals: data and clock.

- The data signal carries bit-serial data. The CSI1/CCP2B transmitter writes the data on each falling edge of the clock. The data are usually transmitted bytewise, LSB first.
- The data clock signal carries the clock signal. The CSI1/CCP2B transmitter writes the data on each falling edge of the clock. The CSI1/CCP2B receiver reads the data on the rising edge of the clock.

6.4.2.2.3.2 Camera ISP CSI1/CCP2B Data/Strobe Signaling (CCP2 only)

Data/strobe signaling consists of two parallel signals: data and strobe.

- The data signal carries the bit-serial data.
- The data strobe signal carries the strobe signal. It toggles when the data signal does not change state. Either the data signal or the strobe signal changes between two data bits. The data and strobe signals may not change simultaneously. The data and strobe signals are used in the receiver to reconstruct the transmission clock. Both fronts of the reconstructed clock are used to sample the data.

6.4.2.2.4 Camera ISP CSI1/CCP2B Protocol Layer

The CSI1/CCP2B protocol layer defines how image-sensor data are transported to the physical layer.

The CSI1/CCP2B protocol layer transports logical channels, which are composed of frames. A frame comprises embedded data and image-sensor data. Each frame is clearly identified by unique synchronization codes: frame start, frame end, line start, and line end. Image-sensor data can have multiple data types (select the data type in the [CCP2_LCx_CTRL](#) [7:2] FORMAT bit field [$x = 0$ to 3]). For details about data types, synchronization code, and FSP encoding/decoding, see [Section 6.2.4.4, Camera ISP CSI1/CCP2 Protocol and Data Formats](#).

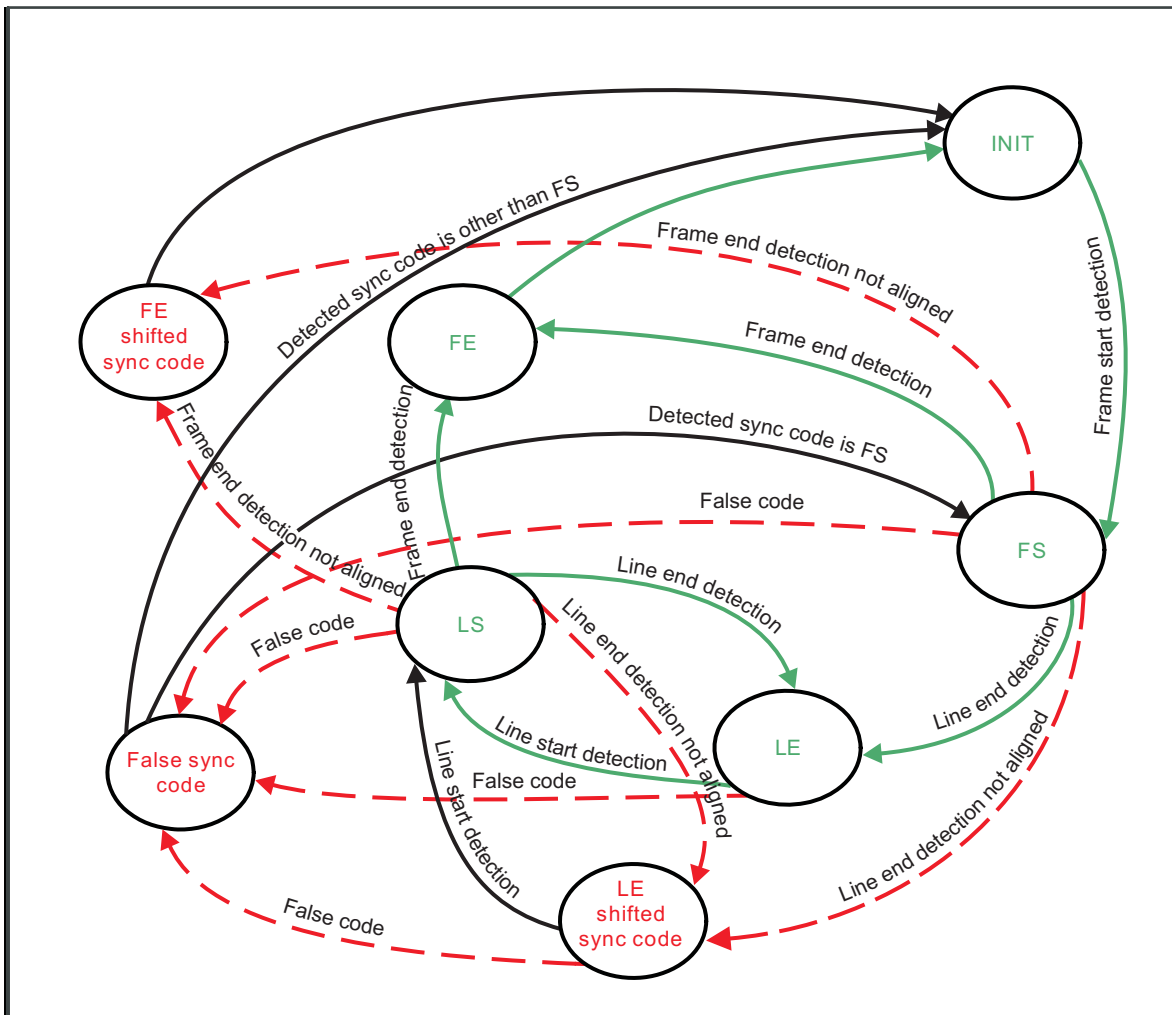

6.4.2.2.4.1 Camera ISP CSI1/CCP2B Synchronization Finite State-Machine

[Figure 6-58](#) shows the CSI1/CCP2B receiver finite state-machine (FSM). The CSI1/CCP2B receiver synchronization operates bitwise.

The expected synchronization code order is FSC, LEC, LSC, and LEC...etc., LSC, LEC, LSC, FEC for all data types except JPEG8. For JPEG8, the expected synchronization code order is FSC, FEC.

If the synchronization code order is not respected, the state-machine goes to FalseSyncCode state. Because line length is always a multiple of 32 bits, the LEC and FEC codes are always aligned on a 32-bit boundary. If LEC or FEC is not aligned on a 32-bit boundary, the state-machine goes to LShiftedSyncCode or FShiftedSyncCode state. [Figure 6-58](#) shows the synchronization state-machine.

Figure 6-58. Camera ISP CSI1/CCP2B Synchronization State-Machine

camisp-194

In case of synchronization code errors, the CSI1/CCP2B receiver can reinitialize itself. No software intervention is required for most synchronization-code errors:

- Line-end shifted code: The receiver either removes the additional bits or adds dummy bits. The next LS synchronization code resynchronizes the state-machine to normal behavior. A shifted line-end (LE) synchronization code triggers an LE_IRQ event.
- Frame-end shifted code: The receiver either removes the additional bits or adds dummy bits. The next FS synchronization code resynchronizes the state-machine to normal behavior. A shifted frame-end (FE) synchronization code triggers an FE_IRQ event.
- False synchronization code: The current frame is lost. The receiver stops acquiring data, flushes its internal FIFO, and asserts the FSC_IRQ event. The next FS synchronization code resynchronizes the state-machine to normal behavior.

6.4.2.2.4.1.1 Camera ISP CSI1/CCP2B Frames

Structure

Figure 6-59 shows the generic (non-JPEG) description of a CSI1/CCP2B frame with synchronization codes. Each CSI1/CCP2B frame line is composed of a finite number of 32-bit words.

Figure 6-59. Camera ISP CSI1/CCP2B Frame Structure: Non-JPEG Data Format

camisp-195

The period between LEC and new is called the line-blanking period. The time between FEC and new FSC is called the frame-blanking period. The CSI1/CCP2B receiver works with line-blanking periods set to 0 or longer.

Figure 6-60 shows CSI1/CCP2B frame structure for the JPEG8 case. The JPEG stream is composed of a finite number of 32-bit words. LSC and LEC synchronization codes are never used when the CSI1/CCP2B interface transports a JPEG bitstream; only FSC and FEC synchronization codes are used.

Figure 6-60. Camera ISP CSI1/CCP2B Frame Structure: JPEG8 Data Format

camisp-196

Data

A frame comprises embedded data and image-sensor data. Figure 6-61 shows the location of embedded data and image-sensor data in the frame. The following definitions apply:

- 0 or more start-of-frame (SOF) status lines can be embedded at the beginning of a CSI1/CCP2B frame.
- Image data comprises pixels of the same data formats. It may contain visible or nonvisible pixels.
- 0 or more end-of-frame (EOF) status line(s) can be embedded at the end of a CSI1/CCP2B frame.
- SOF lines, pixel data, and EOF lines do not overlap.

The CSI1/CCP2B receiver does not use the information contained in the status lines. However, it extracts it and stores it in memory for use by the software. Figure 6-61 shows the CSI1/CCP2B data structure.

Figure 6-61. Camera ISP CSI1/CCP2B Data Structure

FSC	Embedded data - SOF line(s)	LEC	CRC+pad	Line blanking
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC	Pixel data	LEC	CRC+pad	
LSC		LEC	CRC+pad	
[...]		[...]	[...]	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC	Embedded data - EOF line(s)	LEC	CRC+pad	
LSC		LEC	CRC+pad	
LSC		FEC	CRC+pad	
Frame blanking				

camisp-197

Embedded information (SOF and EOF lines):

- Embedded information is never compressed (no DPCM).
- Embedded information covers full lines.
- Embedded information is not encoded in the same data format as pixel data. The CSI1/CCP2B receiver extracts embedded information, but does not modify the data format.
- False-synchronization-code protection is implemented; the receiver ensures that the embedded data contains no synchronization codes.

Pixel data:

- Pixel data can be compressed.
- Pixel data comprises pixels of the same data format.
- False-synchronization-code protection is implemented; the receiver ensures that the pixel data contains no synchronization codes.

6.4.2.2.4.1.2 Camera ISP CSI1/CCP2B Logical Channels

Identification

The CCP2B protocol layer transports logical channels. The purpose of logical channels is to separate different data flows that are interleaved in the same data stream. Each logical channel is identified by a unique channel identification number.

The channel identification number is directly encoded in the 32-bit synchronization codes. Logical channels do apply to the MIPI CSI1 compatible mode; only one channel (channel 0) is used.

As shown in [Figure 6-57](#), the CCP2B receiver monitors the channel identification number and demultiplexes the interleaved data streams. The CCP2B receiver supports up to four concurrent logical channels.

The logical channel identifier is coded in the upper 4 bits (bits 4 to 7) of the last byte of the synchronization codes. [Table 6-23](#) summarizes the default logical channel values used for each channel. The CCP2B programming model allows these values to be overwritten.

Table 6-23. Camera ISP CSI1/CCP2B Logical Channel Values in Synchronization Codes

Logical Channel	Value
Logical channel 0	0x0
Logical channel 1	0x1
Logical channel 2	0x2
Logical channel 3	0x3
Logical channel 4	0x4
Logical channel 5	0x5
Logical channel 6	0x6
Logical channel 7	0x7

Muxing

The logical channels are interleaved at the line level or at the frame level. [Figure 6-62](#) shows the possible situations. Each logical channel can use different data formats.

Figure 6-62. Camera ISP CSI1/CCP2B Muxing

FSC_LC1	Data log chan 1	LEC_LC1	CRC+pad	} Muxing at line level
LSC_LC1	Data log chan 1	LEC_LC1	CRC+pad	
FSC_LC0	Data log chan 0	LEC_LC0	CRC+pad	} Muxing at frame level
FSC_LC2	Data log chan 2	LEC_LC2	CRC+pad	
LSC_LC2	Data log chan 2	LEC_LC2	CRC+pad	
LSC_LC2	Data log chan 2	FEC_LC2	CRC+pad

camisp-198

6.4.2.2.5 Camera ISP CSI1/CCP2B Memory Read Channel

The memory channel can perform the following operations:

- Reads data from memory. It is unpacked and DPCM decompressed if necessary.
- Can send the data to the Video processing hardware
- Can send the data back to memory. It can be DPCM compressed and packed before it is sent to memory.

It cannot receive its input data directly from the sensor, and the logical channels are disabled when the memory channel is enabled.

[Table 6-24](#) summarizes supported modes for memory-to-memory operations.

Table 6-24. Camera ISP CSI1/CCP2B Memory-to-Memory Supported Operations

6.4.2.5.1 Camera ISP CSI1/CCP2B Read Data From Memory

Figure 6-63 shows the data organization in memory.

Figure 6-63. Camera ISP CSI1/CCP2B Data Organization in Memory

The user chooses the start address and the line length using the [CCP2_LCM_SRC_ADDR](#) and [CCP2_LCM_SRC_OFST](#) registers. The image start address normally must point to the beginning of a line because of packing constraints. However it does not necessarily point to the first line of the frame in memory. The [CCP2_LCM_VSIZE](#) [27:16] COUNT bit field specifies the total line count to be read from memory.

It is also possible to skip a certain pixel count ([CCP2_LCM_HSIZE](#) [11:0] SKIP) from the start of the line. However, they are not sent to the video port or back to memory. The [CCP2_LCM_HSIZE](#) [27:16] COUNT bit field specifies the horizontal size of the image. The pixels after the right boundary of the image are not read from memory.

When data are sent to the video port, throughput is imposed by the selected video port clock. Otherwise, it is imposed by the selected interconnect read port clock. The interconnect read rate can be throttled (limiting the maximum data read speed for memory-to-memory operation) using the [CCP2_LCM_CTRL](#) [4:3] READ_THROTTLE bit field. Therefore, it is possible to read the unused data at a higher rate than the used video port data rate. This provides better performance than framing the image in the Video processing hardware.

The data storage format in memory is defined by the [CCP2_LCM_CTRL](#) [18:16] SRC_FORMAT, and [CCP2_LCM_CTRL](#) [23] SRC_PACK registers.

Not all IO format combinations are valid. See [Table 6-24](#) and [Table 6-25](#) for more information.

[Figure 6-64](#) shows how data are packed in memory. Pixel order (left to right in the image) is alphabetical (a,b,c). Therefore, data storage is little endian.

Figure 6-64. Camera ISP CSI1/CCP2B Data Organization in Memory Continued

camisp-206

Table 6-26 summarizes the storage reduction and image width restrictions when data packing is used.

Table 6-26. Camera ISP CSI1/CCP2B Data Packing Benefit and Constraints

	Bits Per Pixel		Storage Reduction	Width Multiple ⁽¹⁾
	Packed	Unpacked		
RAW6	6	8	25%	16
RAW7	7	8	13%	32
RAW8	8	8	0%	4
RAW10	10	16	38%	16
RAW12	12	16	25%	8

⁽¹⁾ In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

6.4.2.5.2 Camera ISP CSI1/CCP2B Memory Read Port Burst Generation

The hardware always uses the largest possible burst size according to the setup. The amount of data read from memory can be higher than what is actually used by the CCP2B receiver. Only full 64-bit words are read. Figure 6-65 shows the data organization in memory.

Figure 6-65. Camera ISP CSI1/CCP2B Data Organization in Memory 3

camisp-207

NOTE:

- A minimum burst size of 2 must be selected for correct operation.
- HWORDS must be paired for correct operation.

Figure 6-64 shows the relationship between the different parameters controlling the burst generation. The `CCP2_LCM_SRC_ADDR` register address of the first data to read is aligned to a 32-byte boundary. The read port fetches `CCP2_LCM_PREFETCH` [13:3] HWORDS of 64-bit words per line using the longest possible burst computed from the `CCP2_LCM_CTRL` [7:5] BURST register and the remaining data to be fetched. When the CCP2B receiver is configured to fetch more data than required, extra data are dropped internally.

6.4.2.2.5.3 Camera ISP CSI1/CCP2B Video Port

The video port always receives unpacked data. It can be enabled using the `CCP2_LCM_CTRL` [2] DST_PORT register. Its clock can be selected with the `CCP2_CTRL` [9:8] VP_OUT_CTRL register.

The data format used by the video port is defined by the `CCP2_LCM_CTRL` [26:24] DST_FORMAT register. See Table 6-25 for a list of supported modes.

6.4.2.2.5.4 Camera ISP CSI1/CCP2B Encode, Pack, and Store Data

This stage is used only when data are sent to memory. Memory destination is selected using the `CCP2_LCM_CTRL` [2] DST_PORT register. The output data format is defined by the `CCP2_LCM_CTRL` [26:24] DST_FORMAT, and `CCP2_LCM_CTRL` [31] DST_PACK registers. Not all possible combinations are supported. See Table 6-24 for details.

The destination address and offset for the output data of the memory channel are set by the `CCP2_LCM_DST_ADDR` and `CCP2_LCM_DST_OFST` registers.

Because of alignment constraints on the interconnect port, the output image width restrictions in Table 6-27 apply.

Table 6-27. Camera ISP CSI1/CCP2B Output Width Restrictions in Memory-to-Memory Operation

Format	Bits/pix	Width Multiple of ⁽¹⁾	Note
RAW6	8	1	Full 32-bit words are written at the end of the line. This last word can eventually include 0s.
RAW6 PACK	6	1	
RAW7	8	1	
RAW7 PACK	7	1	
RAW8	8	1	
RAW10	16	1	
RAW10 PACK	10	16	
RAW12	16	1	Same constraints as RAW8
RAW12 PACK	12	8	

⁽¹⁾ In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

For example, when RAW6 packed data are written to memory, any output width is allowed. However, only full 32-bit words are written to memory. This eventually overwrites some data in memory at the end of a line.

The supported output width is restricted for packed RAW10 and RAW12 data because of the particular bit ordering in those formats (see Figure 6-64).

When the DST_OFST is set to 0, start of lines will be aligned on 4-byte boundaries. When DST_OFST != 0, data are aligned on 32-byte boundaries.

NOTE: The RAW6 and RAW7 data formats do not apply to the MIPI CSI1 compatible mode.

6.4.2.2.6 Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

The CCP2B receiver interface has several image-data operating modes, summarized in [Table 6-28](#). The EXPx formats (x = 8, 16, or 32) are used to expand data up to 8, 16, or 32 bits by padding data with 0s. The Data Size Increase in the Memory column indicates memory overhead versus format without data expansion or/and DPCM compression.

Table 6-28. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints

CCP2_LCx_CT RL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Data Size Increase in Memory (when negative, data compression present)	2D Mode Availability (¹)	Comments
0x0	YUV422 big endian	16	0%	Yes	
0x1	YUV422 little endian	16	0%	Yes	
0x2	YUV420	12	0%	Yes	
0x3	YUV422 + VP	N/A, data are sent to VP, YUV422 + VP = RAW8 + VP	N/A	Yes	
0x3	RAW8 + VP	N/A, data are sent to VP, YUV422 + VP shall be used to output RAW8 +VP to memory	N/A	Yes	
0x4	RGB444 + EXP16	16	50%	Yes	
0x5	RGB565	16	0%	Yes	
0x6	RGB888	24	0%	Yes	
0x7	RGB888 + EXP32	32	33%	Yes	
0x8	RAW6 + EXP8	8	33%	Yes	
0x9	RAW6 + DPCM10 + EXP16	16	167%	Yes	DPCM decompression
0xA	RAW6 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0xB	RAW10 - RAW6 DPCM	6	-40%	Yes	DPCM compression
0xC	RAW7 + EXP8	8	14%	Yes	
0xD	RAW7 + DPCM10 + EXP16	16	128%	Yes	DPCM decompression
0xE	RAW7 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0xF	RAW10 - RAW6 DPCM + EXP8	8	-25%	Yes	DPCM compression
0x10	RAW8, this mode can be used to output RAW6 and RAW7	8	0%	Yes	
0x11	RAW8 + DPCM10 + EXP16	16	100%	Yes	DPCM decompression
0x12	RAW8 + DPCM10 + VP	N/A, data are sent to VP	N/A	Yes	DPCM decompression
0x13	RAW10 - RAW7 DPCM	7	-30%	Yes	DPCM compression
0x14	RAW10	10	0%	Yes	
0x15	RAW10 + EXP16	16	60%	Yes	
0x16	RAW10 + VP	N/A, data are sent to VP	N/A	Yes	
0x17	RAW10 - RAW7 DPCM + EXP8	8	-20%	Yes	
0x18	RAW12	12	0%	Yes	

⁽¹⁾ If 2D mode is available, there are no supplementary constraints on data width. 2D mode is not applicable when sending to video port (VP).

Table 6-28. Camera ISP CSI1/CCP2B Image Data Operating Modes and Alignment Constraints (continued)

CCP2_LCx_CTRL[7:2] Format	CCP2 Data Format	Bits per Pixel (bpp) (when sending data to memory, N/A when sending to VP)	Data Size Increase in Memory (when negative, data compression present)	2D Mode Availability (1)	Comments
0x19	RAW12 + EXP16	16	33%	Yes	
0x1A	RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x1B	RAW10 - RAW8 DPCM	8	-20%	Yes	DPCM decompression
0x1C	JPEG, 8-bit data	N/A	0%	Yes	
0x1D	JPEG, 8-bit data + FSP	N/A	0%	Yes	
0x1E	RAW10 - RAW8 DPCM	8	-20%	Yes	Data right shift
0x1F	RAW8 DPCM12- RAW12 + VP	N/A, data are sent to VP	N/A	Yes	
0x20	RAW10 - RAW8 ALAW	8	-20%	Yes	
0x21	RAW8 DPCM10 - ALAW	8	-20%	Yes	

NOTE:

- Padding data of a 32 bit pixel data stream is handled the same way regardless of the programmed format. Therefore, no storage increase/decrease because it is not compressed/decompressed.
- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros
[CCP2_LCx_CTRL\[15:8\]](#) ALPHA can be used to set an alpha value.
 For RGB444 + EXP16:
 - data_out[31:28] = ALPHA [3:0]
 - data_out[15:12] = ALPHA [3:0]
- EXP32 = Data expansion to 32 bits, padding with alpha
[CCP2_LCx_CTRL\[15:8\]](#) ALPHA can be used to set an alpha value.
 For RGB888 + EXP32: data_out [31:24] = ALPHA [7:0]
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the video-preprocessing hardware is enabled. The programmer must ensure that only one logical channel is enabled to the video preprocessing hardware. The behavior of the hardware is unpredictable if several logical channels to the video preprocessing hardware are enabled simultaneously.
- DPCM10 = Data decompression to 10 bits. Only applies to the RAW6, RAW7 and RAW8 data formats. Disabled if [CCP2_CTRL\[4\]](#) MODE = 0.
- Padding is handled the same way regardless of the programmed format.

6.4.3 Camera ISP CSI2 Receiver

NOTE: There are two CSI2 receivers in the ISP with same functionality. For reading ease, the following section applies to both CSI2A and CSI2C receivers.

6.4.3.1 Camera ISP CSI2 Receiver Features

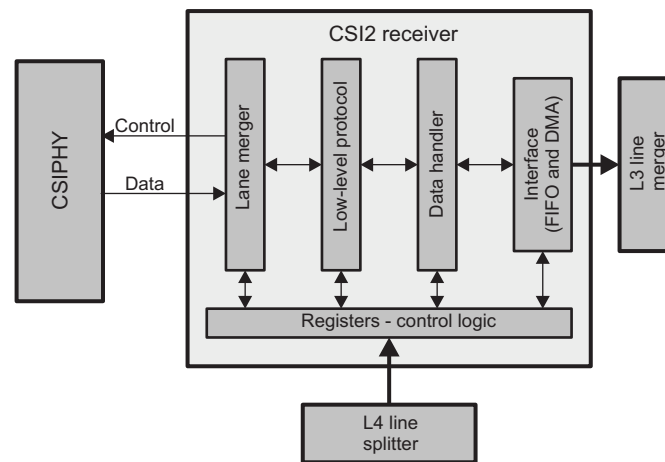

The CSI2 receiver module is a master on the L3 interconnect for storing data in memory and a slave on the L4 interconnect for register access.

The main features of the CSI2 receiver module are:

- Transfer pixels and data received by the PHY to the system memory
- Unidirectional data link
- Minimum of one and maximum of two configurable data links in addition to clock signaling
- Maximum data rate of 1000 Mbps per data pair
- Data merger for 2-data lane configuration
- Error detection and correction by the protocol engine
- DMA engine integrated with dedicated FIFO
- Streaming 1D and 2D addressing modes
- Up to eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- JPEG support for unknown length transfer (no extraction of the thumbnail)
- All primary and secondary MIPI-defined formats are supported (RGB, RAW, and YUV)
- Storage in progressive mode for interlaced stream (using line numbering)
- Conversion of the RGB formats
- Decompression of the RAW formats
- RAW frame transcoding. Including DPCM and A-law compression
- Configuration of PHY
- Fully configurable interface of the PHY: position of the clock and data and order of \pm differential signals for each pair
- Support of DPCM decompression

6.4.3.2 Camera ISP CSI2 Receiver Block Diagram

[Figure 6-66](#) is the block diagram of the CSI2 receiver connected to the PHY.

Figure 6-66. Camera ISP CSI2 Receiver Block Diagram

camisp-238

6.4.3.3 Camera ISP CSI2 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer. The CSI2 PHY is based on the MIPI DPHY Specification version 1.0.

The maximum CSI2 receiver data transfer capacity is 1000 Mbps per data lane.

Data-clock signaling consists of four to six signals: one or two data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the DDR clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 PHY receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or a clock lane. The clock/data lane must be configured before transmission to indicate the byte order while merging the received bytes into a byte stream.

Lanes are configured through the [CSI2_COMPLEXIO_CFG1](#) register for the associated and configured to the receiver PHY. The `CLOCK_POSITION` and `CLOCK_POL` fields configure which lane transmits the clock and define its polarity.

NOTE: If the parallel camera sensor and other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the `CONTROL_CAMERAx_PHY_CAMMOD` bit must be set for CCP2 or CSI2 mode, respectively, (even if only one pair is used as GPI for CPI mode). In that case, the corresponding `CSI2_COMPLEXIO_CFG1.DATAx_POSITION` bit must be set to 0x0 for the lane used in GPI mode.

The [CSI2_COMPLEXIO_CFG1](#) register also contain a bit field affecting PHY power management.

For information about initializing the CSIPHY associated with CSI2, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI2 Receiver](#).

6.4.3.4 Camera ISP CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

6.4.3.4.1 Camera ISP CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bit stream. If the ECC does not match, an interrupt is triggered to the host CPU.

For both long and short packets, the correction is always done if there is only one error per packet.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. [Table 6-29](#) describes the field where events are logged. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQENABLE](#) and [CSI2_CTX_IRQENABLE](#) registers to prevent event generation at a higher level.

Table 6-29. Camera ISP CSI2 ECC Event Logging

	Short Packet	Long Packet
With correction	Global CSI2_IRQSTATUS [12] ECC_CORRECTION_IRQ	Context CSI2_CTX_IRQSTATUS [8] ECC_CORRECTION_IRQ
Without correction	Global CSI2_IRQSTATUS [11] ECC_NO_CORRECTION_IRQ	Global CSI2_IRQSTATUS [11] ECC_NO_CORRECTION_IRQ

The ECC check can be disabled (short and long packet) by writing 0 in the [CSI2_CTRL](#)[2] ECC_EN bit field. Writing 1 enables the ECC check.

6.4.3.4.2 Camera ISP CSI2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an event is triggered to the host CPU.

CRC errors are logged in the CS_IRQ field of the corresponding context register, [CSI2_CTX_IRQSTATUS](#). Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_CTX_IRQENABLE](#) register to prevent event generation at a higher level.

The CRC check can be disabled for a specific context by writing 0 in the [CSI2_CTX_CTRL1](#)[5] CS_EN bit. Writing 1 enables the CRC check.

6.4.3.5 Camera ISP CSI2 RAW Image Transcoding with DPCM and A-law Compression

The CSI2 receiver has a functionality to have an image in raw format transcoded. Transcoding is mainly used to reduce memory footprint and bandwidth when:

- The sensor does not support DPCM compression. So by transcoding A-law and DPCM compressed pixels only occupy 6, 7 or 8-bits/pixel of storage.
- Digital zoom is used. In fact:
 - Data that is not going to be used by further processing does not need to be stored in system memory.
 - Pixels cannot be accessed from random locations in a DPCM compressed frame. Therefore, transcoding avoids memory to memory processing of unused pixels.

[Figure 6-67](#) shows the logical representation of the image transcoding operation. Basically, the steps are as follow:

- Data is extracted from the CSI2 stream
- It is DPCM decompressed if necessary. That's the case when the received stream is DPCM compressed and transcoding has been enabled using the [CSI2_CTX_CTRL1](#)[27:24] TRANSCODE register.
- Data send to the video port cannot be compressed: it is intended to be processed by an HW ISP. Data send to system memory could be optionally compressed.
- Internal data is aligned on MSB when the enter the cropping stage:

- 4 LSBs are 0s when RAW10 data is handled
- 2 LSBs are 0s when RAW12 data is handled
- etc...

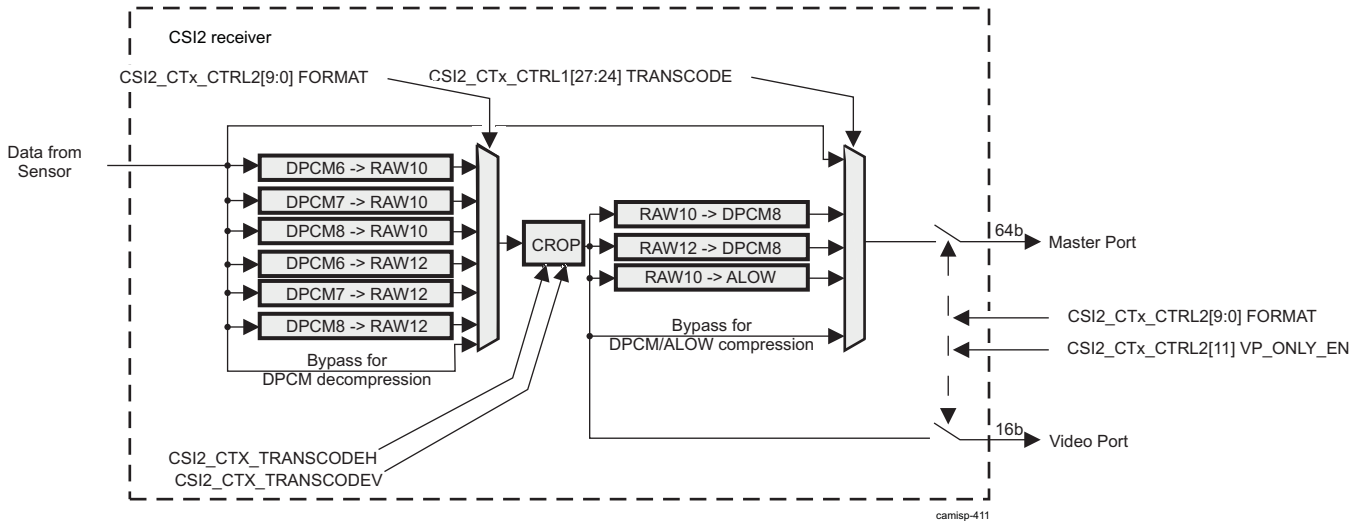

Figure 6-67. Camera ISP CSI2 RAW Image Transcoding Diagram

Table 6-30 shows the input format provided to the cropping engine for a given pixel format provided by the sensor. Formats not listed in the following table are not supported for transcoding.

Table 6-30. Camera ISP Pixel Format Modes

CSI2_CTX_CTRL2 [9:0] Format	CSI2 Data Format	Cropping Engine Input	DPCM Decomp Enabled	Video Port Enabled
0x028	RAW6	RAW6		
0x068	RAW6 + EXP8			
0x029	RAW7	RAW7		
0x069	RAW7 + EXP8			
0x02A	RAW8	RAW8		
0x12A	RAW8 + VP			Yes
0x02B	RAW10	RAW10		
0x0AB	RAW10 + EXP16			
0x0E8	RAW6 + DPCM10 + VP		Yes	Yes
0x12F	RAW10 + VP			Yes
0x229	RAW7 + DPCM10 + EXP16		Yes	
0x2A8	RAW6 + DPCM10 + EXP16		Yes	
0x2AA	RAW8 + DPCM10 + EXP16		Yes	
0x329	RAW7 + DPCM10 + VP		Yes	Yes
0x32A	RAW8 + DPCM10 + VP		Yes	Yes
0x2Cn	USER_DEFINED_BYTE_DATA + DPCM10 + EXP16		Yes	
0x34n	USER_DEFINED_BYTE_DATA + DPCM10 + VP		Yes	Yes

Table 6-30. Camera ISP Pixel Format Modes (continued)

CSI2_CTLx_CTRL2 [9:0] Format	CSI2 Data Format	Cropping Engine Input	DPCM Decomp Enabled	Video Port Enabled
0x02C	RAW12	RAW12		
0x0AC	RAW12 + EXP16			
0x12C	RAW12 + VP			
0x36A	RAW8 + DPCM12 + EXP16		Yes	
0x3AA	RAW8 + DPCM12 + VP		Yes	Yes
0x1Cn	USER_DEFINED_BYTE_D ATA + DPCM12 + EXP16		Yes	
0x14n	USER_DEFINED_BYTE_D ATA + DPCM12 + VP		Yes	
0x3A8	RAW6 + DPCM12 + EXP16		Yes	
0x368	RAW6 + DPCM12 + VP		Yes	Yes
0x369	RAW7 + DPCM12 + EXP16		Yes	
0x3A9	RAW7 + DPCM12 + VP		Yes	Yes
0x02D	RAW14	RAW14		
0x0AD	RAW14 + EXP16			
0x12D	RAW14 + VP			Yes

Image cropping parameters are controlled by software. Figure 6-68 provides a graphical representation of the cropping operation.

Figure 6-68. Camera ISP CSI2 Frame Cropping

NOTE: Hardware does not check for validity of the settings. The following rules must be respected:

- $CSI2_CTx_TRANSCODEH[12:0] HSKIP + CSI2_CTx_TRANSCODEH[28:16] HCOUNT = \text{image width}$
- $CSI2_CTx_TRANSCODEV[12:0] VSKIP + CSI2_CTx_TRANSCODEV[28:16] VCOUNT = \text{image height}$

Furthermore, $CSI2_CTx_TRANSCODEV[28:16] HCOUNT$ must comply with the following alignment constraints. Undefined behavior occurs otherwise. Table 6-31 shows the ranscode alignment constraints

Table 6-31. Camera ISP CSI2 Transcode Alignment Constraints

CSI2_CTLx_CTRL[27:24]] TRANSCODE value	Transcode	HCOUNT must be multiple of
0x0	Disabled	1
0x1	DPCM10 RAW8	1
0x2	DPCM12 RAW8	1
0x3	ALAW10 RAW8	1
0x4	RAW8	1
0x5	RAW10 + EXP16	1
0x6	RAW10	4
0x7	RAW12 + EXP16	1
0x8	RAW12	2
0x9	RAW10 + EXP16	4

Table 6-32 shows the possible combinations between input and output formats supported by the transcoding engine. The Transcode column corresponds to the CSI2_CTLx_CTRL1[27:24] TRANSCODE register of a context.

Table 6-32. Camera ISP CSI2 Supported Transcoding Output Formats

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported
RAW6	0	Disabled	Yes	RAW10	0	Disabled	Yes
	1	DPCM10 RAW8			1	DPCM10 RAW8	Yes
	2	DPCM12 RAW8			2	DPCM12 RAW8	
	3	ALAW10 RAW8			3	ALAW10 RAW8	Yes

	4	RAW8	Yes		4	RAW8	
	5	RAW10 + EXP16			5	RAW10 + EXP16	
	6	RAW10			6	RAW10	
	7	RAW12 + EXP16			7	RAW12 + EXP16	
8	RAW12		8		RAW12		

Table 6-32. Camera ISP CSI2 Supported Transcoding Output Formats (continued)

Cropping Engine Output	Transcode		Supported	Cropping Engine Output	Transcode		Supported
	9	RAW14			9	RAW14	Yes

For RAW10 and RAW12, Software could choose among packed and non packed storage. A-law and DPCM compressed pixels are stored as RAW8 data: each RAW8 container holds a compressed data point. Similarly, RAW data is send over the video port . Enabling of the OCP / video port is controlled as usual by the [CSI2_CTx_CTRL2\[9:0\] FORMAT](#) and [CSI2_CTRL\[11\] VP_ONLY_EN](#) and [CSI2_CTx_CTRL1\[2\] VPFORCE](#) registers.

In order to enable transcoding, The software configures the context normally and in addition, configures the framing using the [CSI2_CTx_TRANSCODEV](#) and [CSI2_CTx_TRANSCODEH](#) registers. The software defines the after transcoding with the [CSI2_CTx_CTRL1\[27:24\] TRANSCODE](#) register.

6.4.3.6 Camera ISP CSI2 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled (see [Section 6.4.3.4.1, ECC](#)). Then, the short packet is written in the [CSI2_SHORT_PACKET\[23:0\] SHORT_PACKET](#) bit field. The ECC field is deleted from the short packet. [Figure 6-69](#) shows the SHORT_PACKET field format.

Figure 6-69. Camera ISP CSI2 SHORT_PACKET Field Format

An event is logged when a short packet is stored in the SHORT_PACKET_IRQ bit in the [CSI2_IRQSTATUS\[13\]](#) register. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQENABLE](#) register to prevent event generation at a higher level.

The application reads the [CSI2_SHORT_PACKET](#) register before the next short packet with a code between 0x8 and 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

6.4.3.7 Camera ISP CSI2 Virtual Channel and Context

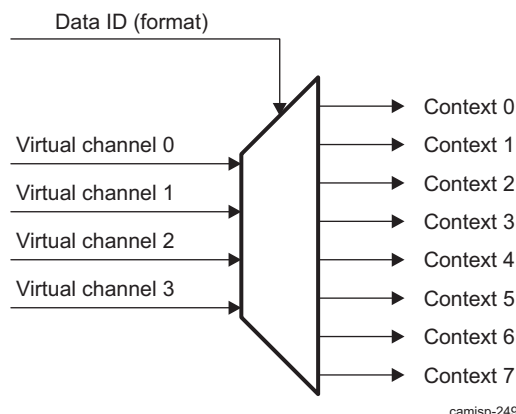

The CSI2 protocol layer transports virtual channels. The purpose of virtual channels is to separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following two bit fields permit configuration of a context:

- [CSI2_CTx_CTRL2\[12:11\] VIRTUAL_ID](#): Configures the virtual ID linked to the current context
- [CSI2_CTx_CTRL2\[9:0\] FORMAT](#): Configures the data format linked to the current context

[Figure 6-70](#) shows the relationships between virtual channels and contexts.

Figure 6-70. Camera ISP CSI2 Virtual Channel to Context

Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by writing 1 in the [CSI2_CT_x_CTRL1\[0\]](#) CTX_EN bit field; writing 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the [CSI2_CT_x_CTRL1\[15:8\]](#) COUNT bit field. Acceptable values are 0:255; 0 stands for infinite capture (no count). After each frame acquired, the count value is decremented by 1. When the count value reaches 0, the [CSI2_CT_x_IRQSTATUS\[6\]](#) FRAME_NUMBER_IRQ event is set and the CTX_EN bit is set to 0. To write a value in the COUNT bit field, the [CSI2_CT_x_CTRL1\[4\]](#) COUNT_UNLOCK bit must be set to 1. If the COUNT_UNLOCK value is 0, a write in the COUNT bit field has no effect.

The [CSI2_CT_x_CTRL3\[15:0\]](#) LINE_NUMBER bit field configures the generation of the [CSI2_CT_x_IRQSTATUS\[7\]](#) LINE_NUMBER_IRQ event. The [CSI2_CT_x_CTRL1\[1\]](#) LINE_MODULO bit configures how the LINE_NUMBER event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo LINE_NUMBER (the event can be generated more than once in a frame).

During a frame capture, the [CSI2_CT_x_CTRL2\[31:16\]](#) FRAME_NUMBER bit field shows the number that identifies the frame received.

6.4.3.8 Camera ISP CSI2 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration (single access, non-streaming and posted writes) is common to the eight channels and is defined in the [CSI2_CTRL](#) register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports the following requests:

- Single write

When an element (the size depends on the data type) is present in the FIFO, the DMA engine initiates a single write.

All single requests sent to the interconnect are back-to-back requests with no idle, if the FIFO has enough data to supply the DMA.

The DMA starts to write in memory using the [CSI2_CT_x_DAT_PING_ADDR\[31:5\]](#) ADDR bit field for the first frame to be transferred and then uses the [CSI2_CT_x_DAT_PONG_ADDR\[31:5\]](#) ADDR bit field and the ping address alternately. So, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The `CSI2_CTxDAT_CTRL1[3]` PING_PONG status bit indicates whether the ping address (`CSI2_CTxDAT_PING_ADDR`) or the pong address (`CSI2_CTxDAT_PONG_ADDR`) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the `CSI2_CTRL[0]` IF_EN register, the pixel data is written in the ping buffer and `CSI2_CTxDAT_CTRL1[3]` PING_PONG = PONG. When the number of FECs received equals the value programmed in the `CSI2_CTxDAT_CTRL1[23:16]` FEC_NUMBER bit field, the pixel data are written in the pong buffer and `CSI2_CTxDAT_CTRL1[3]` PING_PONG = PING. `CSI2_CTxDAT_CTRL1[3]` PING_PONG toggles after the `CSI2_CTxDAT_CTRL1[23:16]` FEC_NUMBER FEC sync code with the virtual channel ID defined is received in the `CSI2_CTxDAT_CTRL2[12:11]` VIRTUAL_ID bit field.

The `CSI2_CTxDAT_CTRL1[23:16]` FEC_NUMBER bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the PING_PONG buffer.

6.4.3.8.1 Camera ISP CSI2 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the `CSI2_CTxDAT_OFST[15:5]` OFST bit field:

- If OFST = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the OFST value sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

```
@Line0 = CSI2_CTxDAT_PING_ADDR @Line1 = @Line0 + CSI2_CTxDAT_OFST
```

```
@Line2 = @Line1 + CSI2_CTxDAT_OFST
```

For the pong frame:

```
@Line0 = CSI2_CTxDAT_PONG_ADDR @Line1 = @Line0 + CSI2_CTxDAT_OFST
```

```
@Line2 = @Line1 + CSI2_CTxDAT_OFST
```

6.4.3.8.2 Camera ISP CSI2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

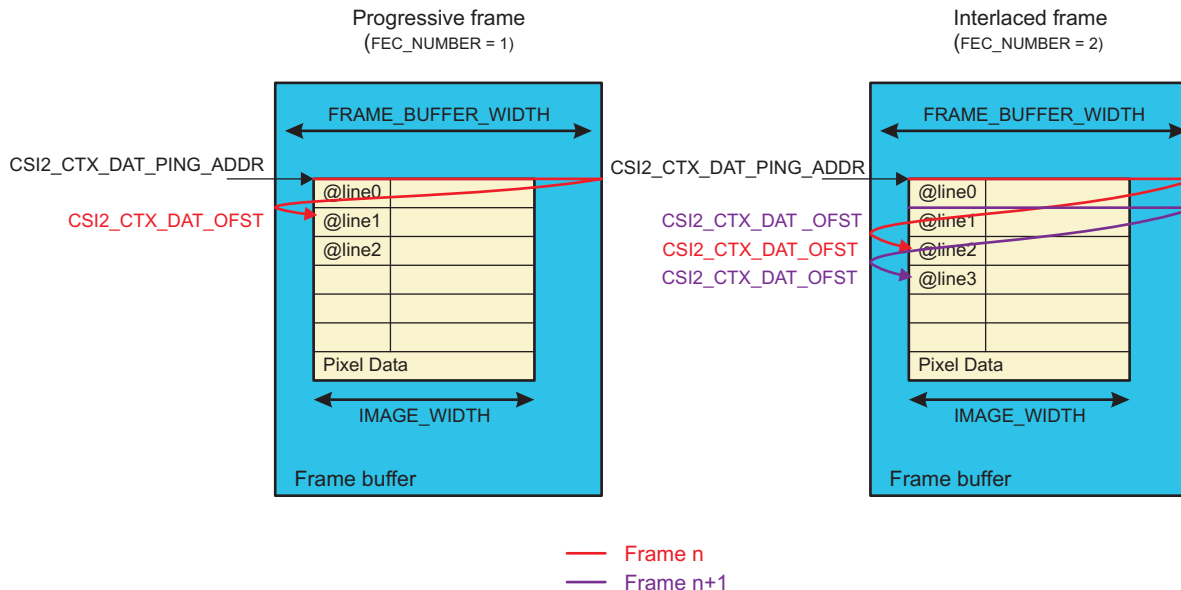

For the ping frame:

```
@LineX = CSI2_CTxDAT_PING_ADDR + CSI2_CTxDAT_OFST * Line_Number
```

For the pong frame:

```
@LineX = CSI2_CTxDAT_PONG_ADDR + CSI2_CTxDAT_OFST * Line_Number
```

Figure 6-71 shows how data are stored in memory regarding DMA configuration.

Figure 6-71. Camera ISP CSI2 Pixel Data Destination Setting in Progressive and Interlaced Mode

6.4.3.9 Camera ISP CSI2 PHYs

The two PHYs in the device act as the interface between the transmitter (camera sensor) and the receivers inside the camera ISP. The modules transform the bit stream divided into one or two serial data lanes into a bit stream compatible with the CSI2 receiver and one clock lane. The two CSIPHY1 and CSIPHY2 have identical functionality, only difference is that CSIPHY1 is limited to one data line. [Figure 6-72](#) shows the CSIPHY overview diagram.

Figure 6-72. Camera ISP CSI2 PHY Overview

The [CSI2_COMPLEXIO1_IRQSTATUS](#) register logs the CSIPHY event. The events that occur are:

- Line power state change (all lanes in ULPM, at least one lane exits ULPM, etc.)
- Error on one lane

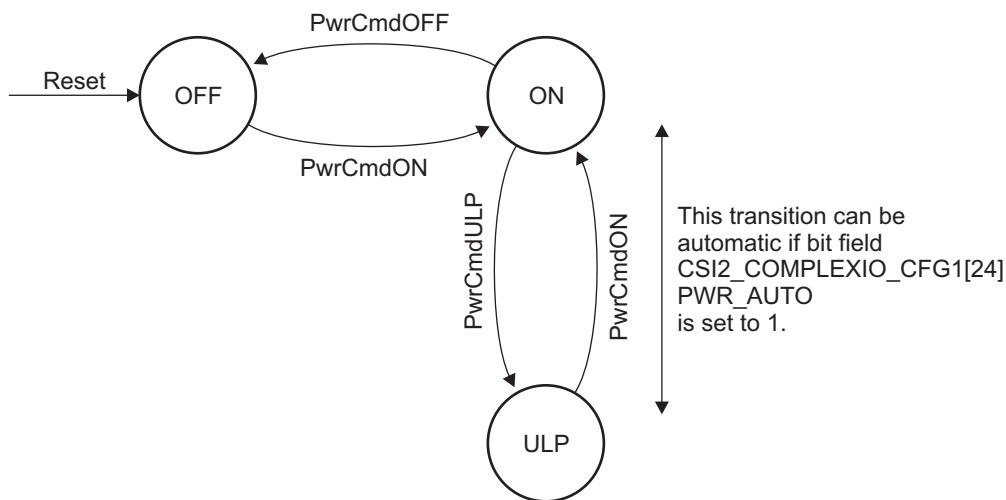

NOTE: For information about initializing the CSIPHY associated with CSI2, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI2 Receiver](#).

Both CSI2A and CSI2C receivers embed a registers to configure/read some PHY parameters:

- The [CSI2_COMPLEXIO_CFG1](#) register reports completion of reset on the different parts of the module and configures timing parameters.

The CSIPHYs have three power modes: on, off, and ULP (ultra-low power). These modes can reflect the ON or ULP power state of the three differential lines if the [CSI2_COMPLEXIO_CFG1\[24\]](#) PWR_AUTO bit is set to 1. If the PWR_AUTO bit is at reset value (0), the PHY power state is controlled by the [CSI2_COMPLEXIO_CFG1\[28:27\]](#) PWR_CMD bit field, which directly defines the power state. [Figure 6-73](#) shows the PHY power finite state machine (FSM).

Figure 6-73. Camera ISP CSIPHY Power FSM

camisp-253

Another register, [CSI2_TIMING](#), is used to control the power state of the CSIPHY module with regards to the differential line state. This register is used to control the mode of the CSIPHY (RxMode or NoRxMode) and the delay between all the differential lines on STOP state and CSIPHY on NoRxMode. The [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 bit field sets the CSIPHY in RxMode or in NoRxMode (stopped mode). The FORCE_RX_MODE_IO1 bit is automatically reset to 0 by hardware when the counter ends and the FSM returns to NoRxMode. Three bit fields ([CSI2_TIMING\[14\]](#) STOP_STATE_X16_IO1, [CSI2_TIMING\[13\]](#) STOP_STATE_X4_IO1, and [CSI2_TIMING\[12:0\]](#) STOP_STATE_COUNTER_IO1) configure the delay between line stop mode and CSIPHY stop mode. The delay represents the number of functional clock (CAM_FCLK) cycles and can be calculated as follows:

$$\text{Total delay in CAM_FCLK cycle} = \text{CSI2_TIMING.STOP_STATE_COUNTER_IO1} \times (1 + \text{CSI2_TIMING.STOP_STATE_X16_IO1} \times 15) \times (1 + \text{CSI2_TIMING.STOP_STATE_X4_IO1} \times 3).$$

[Table 6-33](#) lists the possible values of the delay, in terms of the CAM_FCLK cycles, depending on the values of the STOP_STATE_X16_IO1 and STOP_STATE_X4_IO1 bits.

Table 6-33. Camera ISP CSI2 Possible Time-Out Value for RxMode Counter

STOP_STATE_X16_IO1	STOP_STATE_X4_IO1	Possible Delay Value (in Functional Clock Cycles)
0x0	0x0	8191 (with step of 1)
0x0	0x1	32764 (with step of 4)
0x1	0x0	131056 (with step of 16)
0x1	0x1	524224 (with step of 64)

The state-machine controlling the RxMode is presented in [Figure 6-74](#).

Figure 6-74. Camera ISP CSI2 RxMode and StopState FSM

camisp-254

6.4.3.10 Camera ISP CSI2 Data Decompression

The data compression technique used is differential pulse code modulation (DPCM) and pulse code modulation (PCM).

The CSI2 receiver performs on-the-fly decompression. The decompressed data is either passed to the Video processing hardware or stored in memory.

The data compression method is lossy and does not require any information outside the current encoded/decoded line. This means that all the image lines can be encoded/decoded separately.

There are two different predictors used:

- The simple predictor
This predictor uses only the previous same color component value as a prediction value. Therefore, only two-pixel memory is required.
- The advanced predictor
This predictor uses four previous pixel values, when the prediction value is evaluated. This means that also the other color component values are used, when the prediction value has been defined.

The preferable usage is that simple predictor is used with 10 bits to 8 bits conversion (10 8 10) and the advanced predictor is used with 10 bits to 7 bits and 10 bits to 6 bits conversions (10 7- 10 and 10 6 10). The advanced predictor gives slightly better prediction for pixel value and so the image quality can be improved with it. The simple predictor is very simple and so the processing power and the memory requirements are reduced with it, when the image quality anyway is high enough.

To select DPCM decompression predictor for CSI2 Interface, set the [CSI2_CTx_CTRL2\[10\]](#) DPCM_PRED to 1 for simple predictor or to 0 for advanced predictor.

6.4.3.11 Camera ISP CSI2 EndOfFrame and EndOfLine Pulses

The CSI2 receiver generates two signals to qualify the last pixel of a frame and the last pixel of a line. Software can enable/disable generation of those signals for each context using the [CSI2_CTx_CTRL1\[7\]](#) EOF_EN and [CSI2_CTx_CTRL1\[6\]](#) EOL_EN registers.

6.4.4 Camera ISP Timing Control

6.4.4.1 Camera ISP Timing Control Features

The timing-control module provides two clocks (cam_xclka and cam_xclkb) that can be used by external camera modules. It also generates the control signals (cam_strobe and cam_shutter) for the flash prestrobe, flash strobe, and mechanical shutters.

The timing-control module includes a timing generator and a control-signal generator.

6.4.4.2 Camera ISP Timing Control Overview

Figure 6-75 shows a block diagram of the timing-control module.

Figure 6-75. Camera ISP Timing Control block diagram

camisp-102

6.4.4.2.1 Camera ISP Timing Control Generator

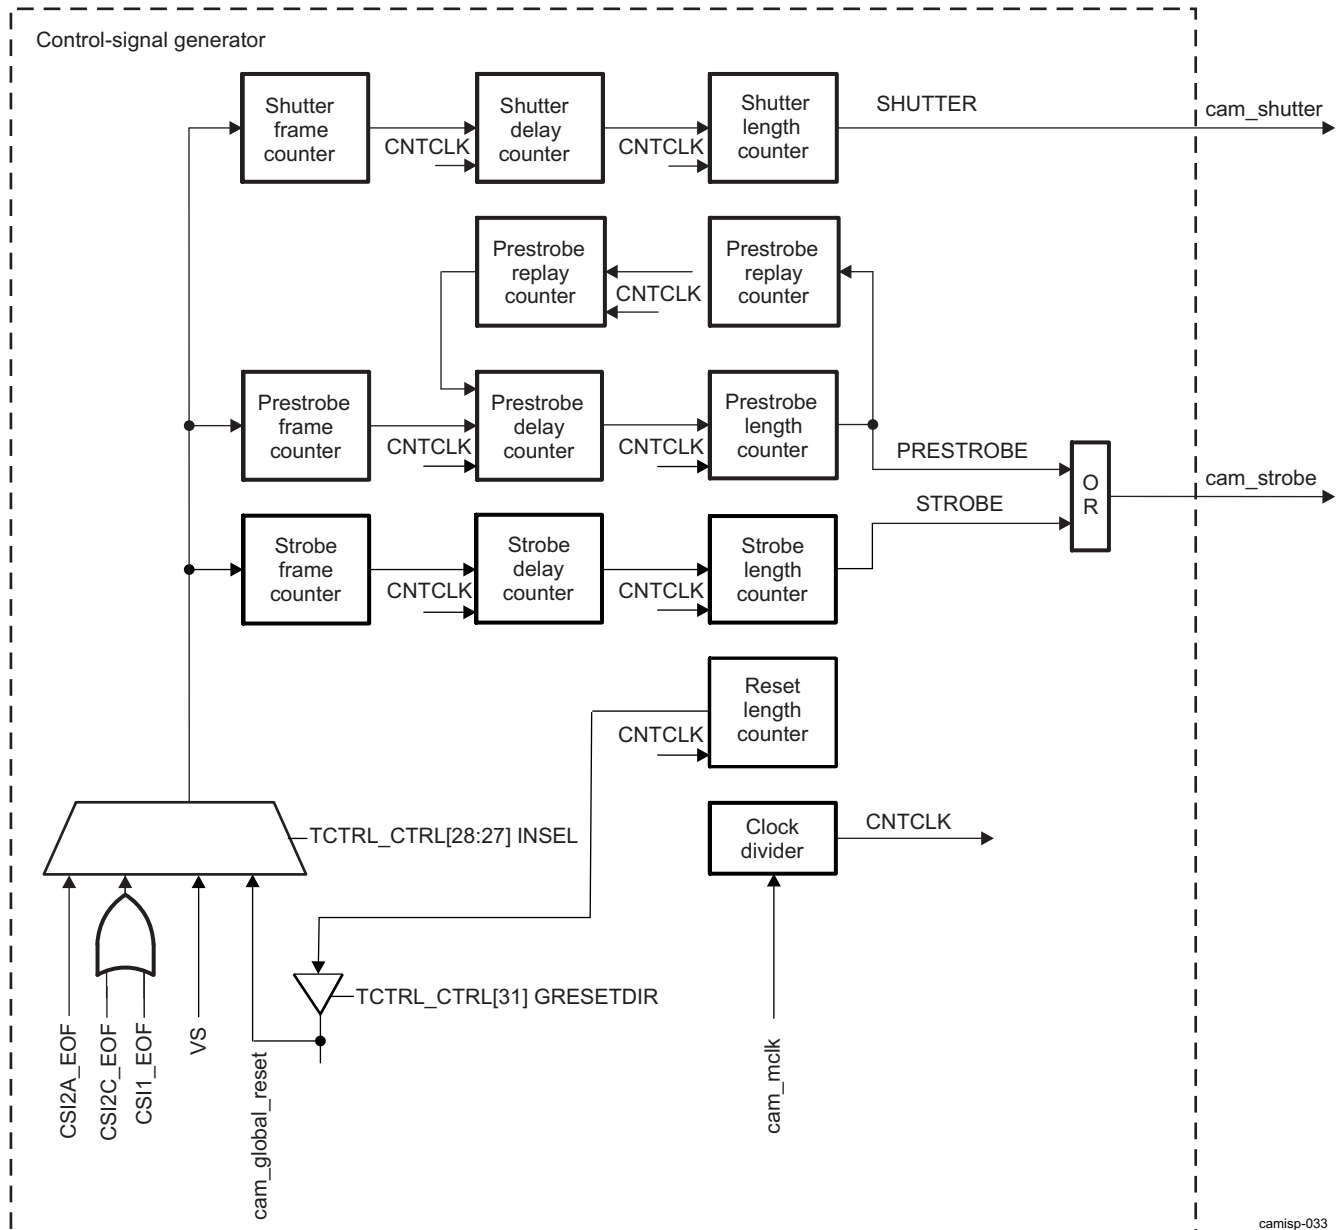

The timing control generates the cam_xclka and cam_xclkb clocks based on the CAM_MCLK frequency, which can be up to 216 MHz. The cam_mclk is used only by the clock generator; the cam_xclka and cam_xclkb clocks are not used internally by the camera ISP. The clock divider is programmable.

The possible frequencies of cam_xclka and cam_xclkb and their respective configurations are described in Section 6.3.1.1.3, *Clock Configuration*.

Table 6-34 summarizes the possible frequencies as a function of the divisor values.

6.4.4.2.2 Camera ISP Timing Control Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam_strobe and cam_shutter. Figure 6-76 shows the principle of control-signal generation.

Figure 6-76. Camera ISP Timing Control Control-Signal Generation

The control-signal generator gathers precise timings for the `cam_strobe` and `cam_shutter` signals, to assert and deassert the signals at known times. The timing-control-signal generator can be synchronized either on the vertical synchronization signal coming from the CSI2A (VP_VS from CSI2A), CSI2C (VP_VS from CSI2C), CSI1/CCP2B (VP_VS from CSI1/CCP2B), or PARALLEL interface (`cam_vs`), or on an externally-generated `cam_global_reset` signal.

A multiplexer controls which of the CSI2A, CSI1/CCP2B or CSI2C, and PARALLEL interface drives control-signal generation. This multiplexer can also select the externally-generated `cam_global_reset` signal as the trigger event. The `TCTRL_CTRL` [31] GRESETDIR register defines the direction of the `cam_global_reset` signal.

- The external generated `cam_global_reset` is used as a trigger when `TCTRL_CTRL` [31] GRESETDIR = 0 and `TCTRL_CTRL` [27:28] INSEL = 3.
- The internally generated `cam_global_reset` is used as a trigger when `TCTRL_CTRL` [31] GRESETDIR = 1 and `TCTRL_CTRL` [27:28] INSEL = 3.

- If the PARALLEL interface is selected, control-signal generation works for both ITU and SYNC modes and on both output ports: video port and shared-buffer-logic (SBL) port.
- If the CSI2A or CSI1/CCP2B/CSI2C interface is selected, control-signal generation works on both output ports: video port and interconnect port.

The cam_global_reset signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on the internally generated cam_global_reset signal. The multiplexer controls whether control-signal generation must be triggered by the internal or external cam_global_reset signal.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the cam_mclk clock. The clock divider is programmable. [Table 6-34](#) summarizes the possible frequencies as a function of the divisor values.

Table 6-34. Camera ISP Timing Control Control-Signal Generator: CNTCLK Frequencies

Divisor Value TCTRL_CTRL [18:10] DIVC	CNTCLK Clock
0 (default)	Clock gated. No clock.
1	216 MHz, free-running.
2	108 MHz
3	72 MHz
4	54 MHz
...	...
510	0.424 MHz
511	0.423 MHz

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

- The frame counter is decreased each time a full new frame is received, based on the EOF events from the CCDC or from receiver modules.
 - A new frame is detected in the CSI2A, CSI1/CCP2B, CSI2C receivers on detection of a frame-start code (FSC) followed by a frame-end code (FEC).
 - A new frame is detected in the CCDC module by using the falling edge of the vertical synchronization signal at the input of the CCDC module.

NOTE: The rising edge of the vertical synchronization signal and the vertical synchronization polarity settings inside the CCDC cannot be used. The modules have no effect on this detection.

- The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass them.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the control-signal assertion length. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

The polarity of the following signals can be individually selected:

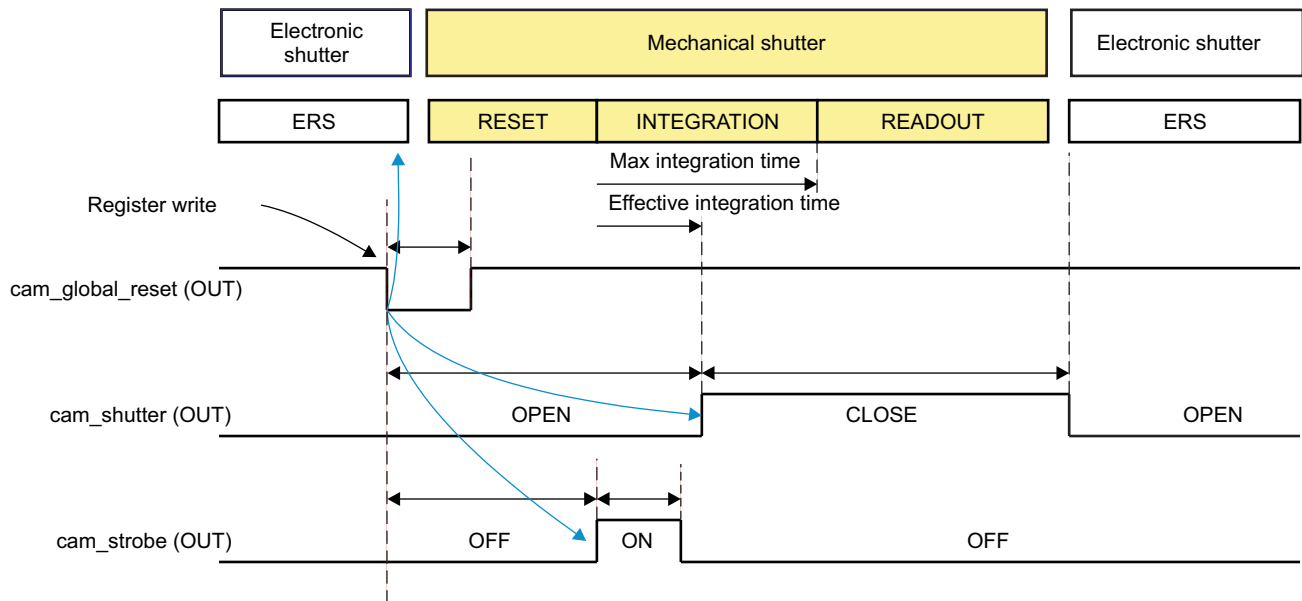

- **TCTRL_CTRL** [26] STRBPSTRBPOL for the prestrobe and strobe signals
- **TCTRL_CTRL** [24] SHUTPOL for the shutter signal
- **TCTRL_CTRL** [30] GRESETPOL for the cam_global_reset signal

The software can trigger the generation of the `cam_global_reset` signal to the camera module. The signal-activation length is programmable. The counter is decreased at every `CNTCLK` clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (`TCTRL_CTRL` [29] `GRESETEN` bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of the `cam_global_reset` signal can be selected (`TCTRL_CTRL` [30] `GRESETPOL` bit).

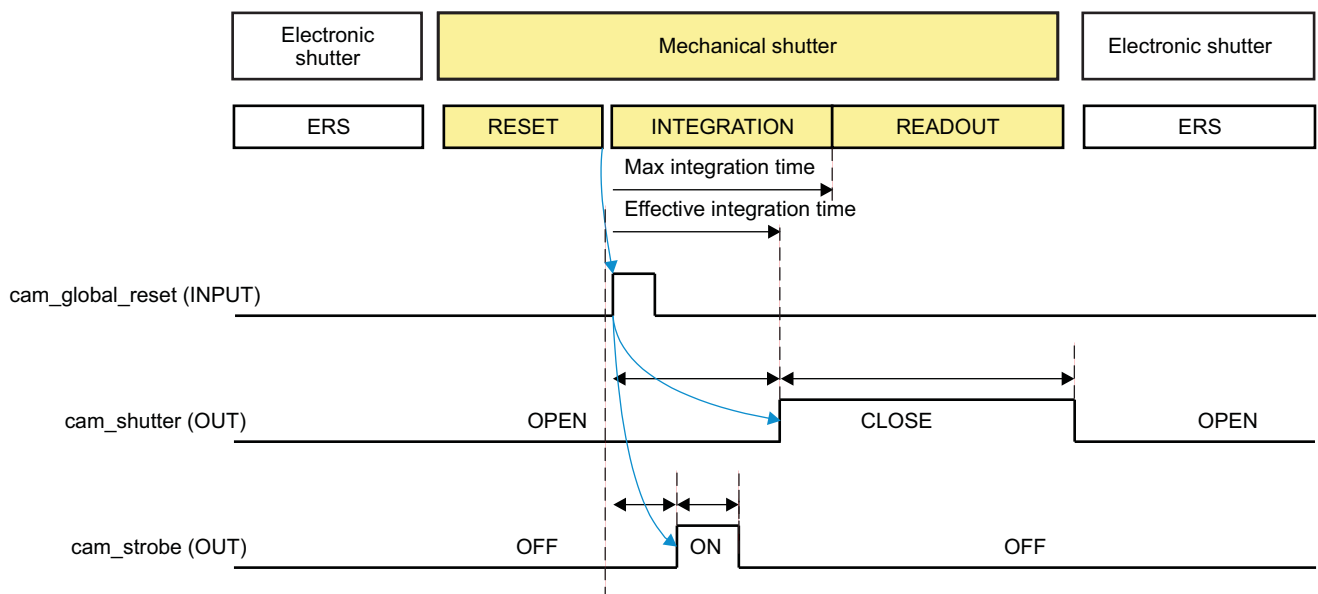

Figure 6-77 shows the use of the `cam_global_reset` signal set as an input or output signal. `cam_global_reset` is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle

Figure 6-77. Camera ISP Timing Control Use of `cam_global_reset` With Global Reset Release Camera Modules

A. `cam_global_reset` is set as a camera ISP output signal

B. `cam_global_reset` is set as a camera ISP input signal

camisp-034

There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (`cam_global_reset`, `cam_shutter`, and `cam_strobe`) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

Mechanical shutter mechanism:

- **Reset:** All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
- **Integration:** The light received by the sensor is transformed into electrical charges that are stored inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is defined by the time between reset release and shutter close.
- **Readout:** The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.

Electronic rolling shutter mechanism (ERS):

- Each line of the sensor is reset separately and read after a fixed amount of time. Expose time is defined by the time between reset and read.

6.4.5 Camera ISP Bridge-Lane Shifter

The bridge-lane shifter module contains a data-lane shifter and an optional bridge:

- The data-lane shifter routes data sent to physical pins to the proper inputs of the CCDC module. It is controlled by the `ISP_CTRL` [7:6] SHIFT register. [Table 6-35](#) describes the different configurations.

Table 6-35. Camera ISP Bridge-Lane Shifter

Sensor	Connected to	Data Lane Shifter 0	Data Lane Shifter 1	Data Lane Shifter 2	Data Lane Shifter 3	Note
8 bits	[7:0]	8 bits	6 bits	4 bits	2 bits	
	[9:2]	10 bits	8 bits	6 bits	4 bits	
	[11:4]	12 bits	10 bits	8 bits	6 bits	
	[13:6]	14 bits	12 bits	10 bits	8 bits	CSI2 only
10 bits	[9:0]	10 bits	8 bits	6 bits	4 bits	
	[11:2]	12 bits	10 bits	8 bits	6 bits	
	[13:4]	14 bits	12 bits	10 bits	8 bits	CSI2 only
12 bits	[11:0]	12 bits	10 bits	8 bits	6 bits	
	[13:2]	14 bits	12 bits	10 bits	8 bits	CSI2 only
14 bits	[13:0]	14 bits	12 bits	10 bits	8 bits	CSI2 only

Blue shading means that the data is too wide for the Video processing hardware: use IVA2.2.

Green shading means that precision is increased for intermediate results.

Orange shading means that precision is reduced.

Unshaded cells imply normal precision.

- An optional bridge allows the packing of bytes into 16-bit words. When it is used, the maximum data rate allowed is increased. The placement of 8-bit data inside 16-bit words is configurable through the `ISP_CTRL` [3:2] PAR_BRIDGE register. This mode can be useful to transfer an YCbCr data stream or compressed stream to memory at very high speed:
 - A minimum line-blanking period of 2 pixels must be obeyed when the bridge is enabled.
 - Some CCDC modules cannot work with the bridge. For details, see [Figure 6-79](#).

6.4.6 Camera ISP Video-Processing Front End

The video-processing front end (VPFE) comprises the CCDC and the lens-shading compensation.

6.4.6.1 Camera ISP CCDC

6.4.6.1.1 Camera ISP CCDC Features

The CCDC is responsible for accepting RAW (unprocessed) image/video data from a sensor. It can also accept YUV video data in numerous formats. For RAW inputs, the CCDC output requires additional image processing to transform the input image to a final processed image. This processing can be performed either on-the-fly in the preview engine, or in software on the IVA2.2 subsystem. In parallel, RAW data input to the CCDC can be used for computing statistics (H3A, histogram) to eventually control image/video tuning parameters. The CCDC module supports the following features:

- **Image sensors:** Supports most image sensors (resolutions up to 4096 x 4096).
- **CCDC interface:** The camera ISP module interface comes either from the external parallel interface or from the output of the CSI2A, CSI2C, CSI1/CCP2B receivers (through the video-port interface). It is a 16-bit interface. To raise this maximum 16-bit interface, the bridge data-lane shifter before the CCDC module allows the packing of 8-bit data into 16 bits (not supported with ITU mode):
 - Supports two synchronization modes:
 - **SYNC mode:** In this mode, the cam_hs and cam_vs signals use dedicated wires. Synchronization signals are provided by either the sensor or the camera ISP. This mode works with 8-, 10-, 11-, 12-, and 14-bit data. It supports both progressive and interlaced image-sensor modules.

NOTE: Input from CSI1/CCP2B is limited to 12 bits, and input from CSI2 is limited to 14 bits.

- **ITU mode:** In this mode, the image-sensor module provides an ITU-R BT 656-compatible data stream. Horizontal and vertical synchronization signals are not provided to the interface. Instead, the data stream embeds SAV and EAV synchronization code. This mode works in 8- and 10-bit configurations.
- **RAW data processing:** Output data can go directly to memory for software processing, or to the PREVIEW module for further processing. The operations include:
 - Optical clamp
 - Black-level compensation
 - Faulty-pixel correction
 - 2D map based lens-shading compensation (LSC)
 - Data formatter and video port
 - Output formatter and Culling
 - DC subtract
- **YUV data processing:** The output data can go directly to memory for software processing or to the Resizer module for further processing. The operations include:
 - Output formatter and Culling
 - DC subtract
- **Memory ports:** The CCDC module can access memory as a master through the CRSBL, so it does not require the assistance of the system DMA.

6.4.6.1.2 Camera ISP CCDC Block Diagram

Figure 6-78 shows the top-level block diagram of the CCDC module.

Figure 6-78. Camera ISP CCDC Block Diagram

camisp-038

The data flow through the module differs, depending on whether the input is RAW data or YUV data. It also depends on the application scenario. See [Table 6-21](#) for ISP and CCDC allowed data flows.

For RAW8/10 data ([CCDC_SYN_MODE](#) [13:12] INPMODE = 0 [CCDC_REC656IF](#) [0] REC656ON = 0), the following functions apply:

- Video-preview and video-capture data flows can pass through the optical-clamp, black-level compensation, faulty-pixel correction, lens-shading compensator, and data-reformatter submodules. Output is transmitted to the computing statistics (H3A, histogram) modules for further processing.
- JPEG still image capture data is not processed by the internal CCDC modules. The data flow is sent to memory through the SBL, Circular buffer, and MMU to be read by the external JPEG CODEC.
- RAW still-image-capture data flow typically passes through the optical clamp, black-level compensation, faulty-pixel correction, lens-shading compensator and output-formatter submodules.

For YUV data ([CCDC_SYN_MODE](#) [13:12] INPMODE = 1 or 2 [CCDC_REC656IF](#) [0] REC656ON = 1), the following functions apply:

- Data can be written to memory directly through the central-resource SBL module or sent to the Resizer module for upscaling or downscaling.

For JPEG data coming from the camera parallel interface (CPI), the following settings apply for proper CCDC configuration:

- [ISP_CTRL](#)[29] [CCDC_WEN_POL](#) = Depending on the JPEG sensor
- [CCDC_SYN_MODE](#)[5] [EXWEN](#) = 1
- [CCDC_SYN_MODE](#)[13:12] [INPMOD](#) = 0
- [CCDC_SYN_MODE](#)[11] [PACK8](#) = 1
- [CCDC_SYN_MODE](#)[10:8] [DATSIZ](#) = 7

- `CCDC_CFG[8] WENLOG = 1`
- `CCDC_VERT_LINES[14:0] NLV = 0`
- `CCDC_HSIZE_OFF[15:0] LNOFST = 0`

6.4.6.1.3 Camera ISP CCDC Functional Operations

6.4.6.1.3.1 Camera ISP CCDC SYNC CTRL Module

The SYNC CTRL module receives the pixel-clock signal from the image sensor (PCLK). The module can be slave or master of the horizontal and vertical synchronization signals (HS and VS) and of the field-identification signal (FIELD).

The HS, VS, and FLD signals can be set as inputs or outputs. The polarity of the HS, VS, and FLD signals can be set as positive or negative. If the HS, VS, and FLD signals are output, the signal length can be set.

6.4.6.1.3.2 Camera ISP CCDC Input Sampling and Formatting

- Data is latched by the pixel clock.
- Pixel-clock polarity can be either rising- or falling-edge. This is set through `ISP_CTRL [4] PAR_CLK_POL`.
- Data can be interpreted as normal or inverted (`CCDC_SYN_MODE[6] DATAPOL`).
- For RAW data:
 - Data is clipped to the number of LSBs specified in the `CCDC_SYN_MODE [10:8] DATSIZ` field. This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment if data is written to memory.
- For YUV data (BT656 or SYNC mode):
 - The MSB of the chroma signal can also be inverted (`CCDC_CFG [13] MSBINVI`). It adds 128 to chrominance signals, to be compatible with several sensors.
- BT656 decoder: Separates data and synchronization signals. This module outputs HS, VS, and FIELD signals.

6.4.6.1.3.3 Camera ISP CCDC Initial Processing

Optical Clamp

The optical black clamping function provides a means of averaging the optically black pixels and subtracting that value from each input pixel as a first step. The goal is to remove an offset caused by the sensor technology.

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (`CCDC_CLAMP [24:10] OBST`) of each line (`CCDC_CLAMP [30:28] OBSLEN`) and for the number of indicated lines (`CCDC_CLAMP [27:25] OBSLN`), plus an optional gain adjustment (`CCDC_CLAMP [4:0] OBGAIN`), and subtracting this value from the image data at the succeeding line. Users can control the position of the black pixels, the number of pixels (1, 2, 4, 8, or 16) in each line averaged, and the averaged number of lines (1, 2, 4, 8, or 16).

Alternately, users can disable black clamp averaging (`CCDC_CLAMP [31] CLAMPEN`) and select a constant black value for subtraction (`CCDC_DCSUB [13:0] DCSUB`), instead of using the calculated average value.

NOTE: For YUV data, this operation subtracts a fixed value (`CCDC_DCSUB [13:0] DCSUB`) from the luminance sample. To disable this operation, set the subtraction value to zero. This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes (`CCDC_SYN_MODE [13:12] INPMOD == 2 || CCDC_REC656IF [0] REC656ON == 1`).

This function does not clip negative results to 0 for YUV 8 bit input or REC656 input modes (`CCDC_SYN_MODE [13:12] INPMOD == 2 || CCDC_REC656IF [0] REC656ON == 1`).

Figure 6-79 shows an optical clamp representation.

Figure 6-79. Camera ISP CCDC Optical Clamp Representation

camisp-106

Black-Level Compensation

After the optical clamp, black-level compensation is applied to the data. In this operation, a fixed value, depending on the color (R/Ye, Gr/Cy, Gb/G, and B/Mg), can be subtracted from the data. The offset ([CCDC_BLKCOMP](#) register, fields R_YE, GR_CY, GB_G, B_MG) applied to each data sample is selected according to the pixel position (0/1/2/3) and the color (0/1/2/3) specified for each pixel position ([CCDC_COLPTN](#)). The color pattern definition is flexible to accommodate different sensor types (such as Bayer CFA sampling, VGA Movie Mode).

Faulty-Pixel Correction

Faulty-pixel correction in the CCDC module requires the camera driver to have information about the image-sensor faulty-pixel number and positions. This method leads to the best image quality. However, if the position of the faulty pixels is unavailable to the camera driver, it can apply another faulty-pixel correction algorithm in the preview module. This algorithm leads to lower-quality images.

The CCDC module implements an optional ([CCDC_FPC](#) [15] FPCEN) faulty-pixel correction operation using a look-up table stored in external memory, which contains information about the horizontal and vertical positions of the pixels to be corrected, as well as the type of operation to be performed on the pixels. The [CCDC_FPC_ADDR](#) register specifies the starting address in memory for the faulty-pixel correction table.

NOTE: The memory address must be 64-byte-aligned (6 LSBs are ignored).

NOTE: For YUV data, the faulty-pixel correction operation is not applicable and must be disabled/bypassed ([CCDC_FPC](#) [15] FPCEN).

6.4.6.1.3.4 Camera ISP CCDC Data Formatter, Lens-Shading Compensation, and Video-Port Interface

NOTE: For YUV data, the data formatter, lens-shading compensation, and video-port interface must be bypassed ([CCDC_FMTCFG](#) [15] VPEN = 0x0 and [CCDC_SYN_MODE](#) [18] VP2SDR = 0x0).

The data-formatter module can be enabled to rearrange data after the faulty-pixel correction operation. It is intended to be used:

- When output data lines from the CCDC include pixels from multiple resolution lines. Internally, these sensors combine pixels from multiple horizontal lines into one output pseudoline.
- To smooth bandwidth. This helps reduce peak bandwidth when image cropping is used with the Resizer.

The reformatter module performs the decomposition before the remainder of the normal CCDC processing stages.

The lens-shading compensation (LSC) module can be placed at two different locations:

- Before the data reformatter. It can only be used for Bayer sensors. The H3A video port gets the shading corrected image.
- After the data reformatter. This setup is required for non-Bayer sensors. Histogram and preview modules get the shading corrected image; however, H3A receives a non-corrected image.

Video-port/data-formatter output can also be saved to memory (instead of the RAW data). When [CCDC_SYN_MODE](#) [18] VP2SDR is set to 1, video-port data is sent to the output formatter. In addition, the [CCDC_SYN_MODE](#) [17] WEN bit must be enabled to store the output to memory.

The data-formatter and video-port interfaces are only 10 bits wide; therefore, the input data must be adjusted as it enters these modules. For flexibility, the bits to be retained can be selected by [CCDC_FMTCFG](#) [14:12] VPIN.

The reformatter decomposes each input line into multiple output lines with new, internally generated HS/VS signals. The reformatter sends it to memory or to other camera ISP modules. These new HS/VS signals, rather than the original sensor HS/VS signals, then gate the downstream processing.

Conversion Area Select Parameters

When the data formatter is enabled, HS/VS signals are still generated as output ([CCDC_SYN_MODE](#) [16] VDHDEN = 0x1). The settings for these output signals are in the following fields:

- [CCDC_HD_VD_WID](#)[27:16] HDW
- [CCDC_HD_VD_WID](#)[11:0] VDW
- [CCDC_PIX_LINES](#)[31:16] PPLN
- [CCDC_PIX_LINES](#)[15:0] HLPRF

NOTE: These four registers are not used when HS/VS signals are input signals ([CCDC_SYN_MODE](#) [16] VDHDEN = 0x0).

NOTE: The settings reflect those for the sensor readout frame, not the resultant reformatted frame.

Registers [CCDC_FMT_HORZ](#) and [CCDC_FMT_VERT](#) affect the input framing even if data formatter is disabled.

Registers [CCDC_HORZ_INFO](#), [CCDC_VERT_START](#), and [CCDC_VERT_LINES](#) control the output formatter framing. It is used only when the CCDC output is sent to memory.

[Figure 6-80](#) shows the data formatter conversion area selection.

Figure 6-80. Camera ISP CCDC Data Formatter Conversion Area Selection

camisp-045

Line Decomposition

When enabled, the reformatter can be configured to operate in line-alternating mode or program mode ([CCDC_FMTCFG](#) [1] LNALT).

When line-alternating mode is enabled, the reformatter swaps even and odd lines. Basically, the 0th input line is output as the first line, the first input line is output as the 0th line, and so on. If this option is set, the start and number of lines for the formatter ([CCDC_VERT_START](#) and [CCDC_VERT_LINES](#)) must be even.

In program mode, or normal reformatter mode, the goal is to convert a single line of movie mode data to 1, 2, 3, or 4 lines of Bayer data. Each incoming line is decomposed according to the data-formatter settings and buffered into an internal line memory. The readout of the resultant multiple reformatted lines occurs as the next input line is being read from the sensor (and reformatted) to ensure that all output lines are fully constructed. The reformatter is subject to the restrictions listed in [Table 6-36](#).

Table 6-36. Camera ISP CCDC Reformatter Output Limitations

Number of Output Lines/Input Line	Max Pixels/Output Line
1	4 * 1376
2	2 * 1376
3	1 * 1376
4	1 * 1376

The reformatter derives its flexibility from supporting up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. Each of the 8 addresses supports either auto increment or auto decrement. This capability is the key for supporting a multitude of readout patterns. The following examples show the programmability of the reformatter. Decomposition is controlled by defining the following parameters:

- [CCDC_FMTCFG](#) [3:2] LNUM
Number of lines into which each input line is to be decomposed
- [CCDC_FMTCFG](#) [11:8] PLEN_EVEN
Number of program entries on even line
- [CCDC_FMTCFG](#) [7:4] PLEN_ODD
Number of program entries on odd line
- [CCDC_FMT_ADDRx](#) (x = 0:7)
Output line in which the original pixel is to be placed, and initial address on the output line
- [CCDC_PRGEVEN0](#) or [CCDC_PRGEVEN1](#)
Program to be run on the even input lines
- [CCDC_PRGODD0](#) or [CCDC_PRGODD1](#)
Program to be run on the odd input lines

The CCDC_FMT_ADDRx registers define 8 address pointers (ADDR0 to ADDR7) that define which output line the input pixel belongs to, and the starting address (position) on that output line. Users can use up to 8 address pointers. The address pointer can be incremented or decremented, depending on the input pixel pattern. The address value computed should always follow the reformatter rules as formerly stated and should never be negative.

Lens-Shading Compensation

- Overview

The purpose of the LSC function is lens-shading correction by multiplying an image with a gain factor 2-D map, pixel by pixel. The image must be in Bayer CFA format having a 2x2 color pattern. The gain factor map is stored in external memory downsampled, and is accessed and upsampled by the LSC module before being applied to the pixel data.

The LSC function is useful for lens-shading compensation and for scene- and image-dependent lighting adjustment. Downsampled gain map reduces memory requirements for storage and bandwidth requirements for access of the gain maps in external memory.

- Features supported

- The memory stored gain map is MxN downsampled, M being the horizontal sampling factor, N being the vertical sampling factor, M and N being {4, 8, 16, 32, 64} independently and N M
- 8-bit entries in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0)
- Up to 10-bit unsigned image data input/output
- Up to 4096 x 3072 image dimension

- Functional description

The lens-shading correction module multiplies an image by a gain map that is stored downsampled in memory. The gain map can be dependent on aperture, lens-shading characteristics, and other photographic settings. It is generally used to correct the dim corner effect, but can also be used to implement adaptive lighting adjustment.

Separate horizontal and vertical sampling factors allow the lens-shading correction to work with the normal 1:1 aspect ratio image pixels, as well as tall-and-skinny pixels typical in the sensors preview mode image data.

6.4.6.1.3.5 Output Formatter

The output formatter starts with a framing selection to limit the processing area by setting [CCDC_HORZ_INFO](#), [CCDC_VERT_START](#), and [CCDC_VERT_LINES](#) registers. This framing selection is applied in addition to the framing applied at the beginning and at the end of the data formatter operation if the video-port path to memory is selected ([CCDC_SYN_MODE](#) [18] VP2SDR).

The option to send the CCDC output to the Resizer module ([CCDC_SYN_MODE](#) [19] SDR2RSZ) should not be used when in RAW data mode, because the Resizer operates only on YUV format data. Use the preview module when resizing is desired in RAW data mode.

Low-Pass Filter (LPF)

An optional horizontal low-pass antialiasing filter can be applied ([CCDC_SYN_MODE](#) [14] LPF) after reframing. The low-pass filter consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

NOTE: For YUV data, the LPF must be disabled ([CCDC_SYN_MODE](#) [14] LPF = 0x0).

Culling

An optional culling operation can be enabled ([CCDC_CULLING](#) register). This operation allows selected pixel data to be culled (deleted) from a line ([CCDC_CULLING](#) [31:24] CULHEVN, [CCDC_CULLING](#) [23:16] CULHODD – 8-bit repeating mask, one per field) and selected lines to be culled from a frame ([CCDC_CULLING](#) [7:0] CULV).

[Figure 6-81](#) is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, [CCDC_CULLING](#) = 0x239A0066:

- [CCDC_CULLING](#) [31:24] CULHEVN = 0x23
- [CCDC_CULLING](#) [23:16] CULHODD = 0x9A
- [CCDC_CULLING](#) [7:0] CULV = 0x66

NOTE: Culling can be used with YUV data, but care must be taken to preserve the YUV422 output format.

Figure 6-81. Camera ISP CCDC/Culling: Example for Decimation Pattern

	LSB						MSB	
CCDC_CULLING [31:24] CULHEVEN	0	0	1	0	0	0	1	1
CCDC_CULLING [23:16] CULHODD	1	0	0	1	1	0	1	0

2 nd line									1
3 rd line									0
4 th line									0
5 th line									1
6 th line									1
7 th line									0

CCDC_CULLING[7:0]
CULV

camisp-048

A-Law Compression

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied ([CCDC_ALAW](#) [3] CCDTBL) as the final processing stage. Using this causes data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected ([CCDC_ALAW](#) [2:0] GWDI).

The preview module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

NOTE: A-Law compression must not be used ([CCDC_ALAW](#) [3] CCDTBL = 0) with YUV data.

Figure 6-82 show the A-Law table.

Figure 6-82. Camera ISP CCDC A-Law Table

Line-Output Control

NOTE: Line-output control can be used with YUV data.

The CCDC final stage is line-output control, which controls how the input sensor lines are written to memory. The value of `CCDC_SDR_ADDR` [31:0] ADDR defines the starting address where the frame should be written in memory. The value of `CCDC_HSIZE_OFF` [15:0] LNOFST defines the distance between two lines for each output line to memory. The starting address and line-offset values should be aligned to 32-byte boundaries; that is, either 16 or 32 pixels, depending on the `CCDC_SYN_MODE` [11] PACK8 setting. Register `CCDC_SDOFST` can be used to define additional offsets, depending on the field ID and even/odd line numbers. This provides a means to deinterlace an interlaced 2-field input and to invert an input image vertically. See [Table 6-37](#).

Table 6-37. Camera ISP CCDC `CCDC_SDOFST` Description

Register	Description
<code>CCDC_SDOFST</code> [14] FIINV	Invert interpretation of the field ID signal
<code>CCDC_SDOFST</code> [13:12] FOFST	Offset, in lines, of field = 1
<code>CCDC_SDOFST</code> [11:9] LOFST0	Offset, in lines, between even lines on even fields (field 0)
<code>CCDC_SDOFST</code> [8:6] LOFST1	Offset, in lines, between odd lines on even fields (field 0)
<code>CCDC_SDOFST</code> [5:3] LOFST2	Offset, in lines, between even lines on odd fields (field 1)
<code>CCDC_SDOFST</code> [2:0] LOFST3	Offset, in lines, between odd lines on odd fields (field 1)

Line Output Control: 2D Addressing Example

The CCDC memory port can be configured to write a subimage into a bigger image buffer. This feature is useful for overlaying a video preview flow with the rest of the display. To use this feature, the `CCDC_SDR_ADDR` [31:0] ADDR register points to the first pixel to write and the `CCDC_SDOFST` [13:12] FOFST is set to the size of one line of the destination buffer.

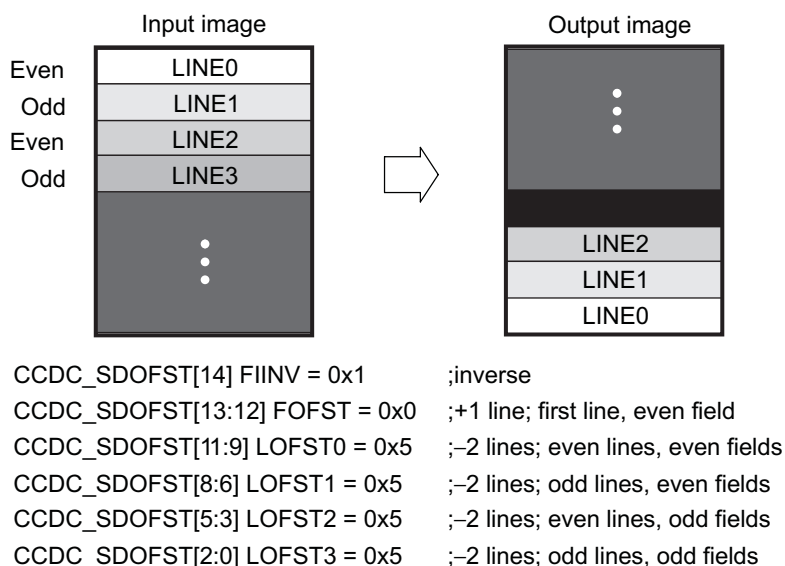

NOTE:

- This mode can be used only when the source and destination buffers use the same image format.
- 2D addressing is also supported by other camera ISP modules.

Line-Output Control: Examples

Figure 6-83 shows an example of sample formats of input and output images.

Figure 6-83. Camera ISP CCDC/Line-Output Control: Sample Formats of Input and Output Images

camisp-051

Output Format

The data bits comprising each pixel are stored in the lower bits of a 16-bit memory word and the unused bits are zero-filled. The memory data format is shown in Table 6-38. The format is determined by the [CCDC_SYN_MODE](#) [10:8] DATSIZ field.

If 8-bit data is input, or if A-Law compression is applied, the data can be packed through the [CCDC_SYN_MODE](#) [11] PACK8 setting so that a pixel occupies only 8 bits.

Data is output to memory only when enabled through the [CCDC_SYN_MODE](#) [17] WEN setting. The pixels are ordered in little-endian format.

Table 6-38. Camera ISP CCDC Memory Output Format for RAW Data

	Upper word		Lower word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
16 bit	Pixel 1		Pixel 0	
15 bit	0	Pixel 1	0	Pixel 0
14 bit	0	Pixel 1	0	Pixel 0
13 bit	0	Pixel 1	0	Pixel 0
12 bit	0	Pixel 1	0	Pixel 0
11 bit	0	Pixel 1	0	Pixel 0
10 bit	0	Pixel 1	0	Pixel 0
9 bit	0	Pixel 1	0	Pixel 0
8 bit	0	Pixel 1	0	Pixel 0
8-bit packed	Pixel 3	Pixel 2	Pixel 1	Pixel 0

NOTE: YUV data is stored in memory in packed YUV422 mode, using two pixels per 32 bits, as shown in [Table 6-39](#).

Table 6-39. Camera ISP CCDC Memory Output Format for YUV Data

Memory Address	Upper Word		Lower Word	
	MSB(31)	LSB(16)	MSB(15)	LSB(0)
N	Y1	Cr0	Y0	Cb0
N + 1	Y3	Cr1	Y2	Cb1
N + 2	Y5	Cr2	Y4	Cb2

6.4.6.1.4 Camera ISP CCDC DMA

The CCDC module is a master. It has its own address generator and sends addresses and data to the central-resource shared-buffer logic. The central-resource shared-buffer logic arbitrates the data requests and generates the bursts to memory.

6.4.6.1.5 Camera ISP CCDC Memories

The CCDC module has one memory:

- REFORMATTER BUFFER: 3 x 1376 x 40 bits
- LSC PREFETCH BUFFER: 1536 x 32 bits

6.4.7 Camera ISP Video-Processing Back End

The video-processing back end (VPBE) comprises the preview and Resizer modules.

6.4.7.1 Camera ISP VPBE Preview Engine Features

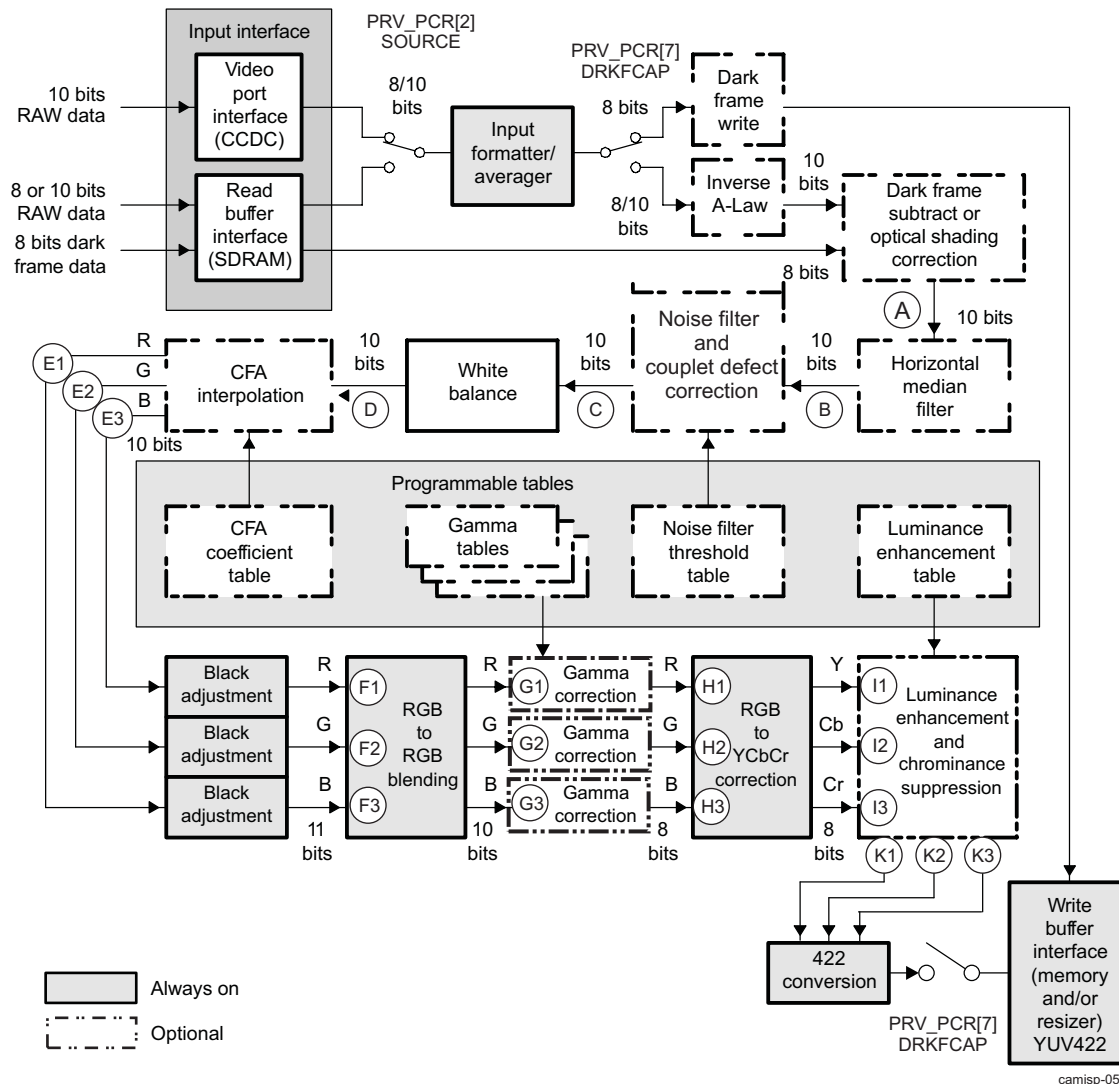

The preview module is responsible for transforming data from a RAW image sensor into YUV422 data that is amenable to still-image encoding, video encoding, or display. It supports the following features:

- Flexible input: Module input data can come from the RAW image sensor (10 bits) or from memory (8 or 10 bits).
- Flexible input formats: Bayer RGB color filter array, complementary-color filter array, Super CCD Honeycom® sensors
- Horizontal averaging by a factor of 1, 2, 4, or 8 in the horizontal direction. The preview module can output a maximum of only 4096 pixels horizontally due to fixed memory-line sizes.
- A-Law decompression: Transforms nonlinear 8-bit data to 10-bit linear data. The CCDC module can perform A-Law compression.
- Noise reduction and faulty-pixel correction:
 - Dark-frame capture and subtraction
 - Horizontal median filter
 - Programmable noise filter: 3x3 kernel of same color pixels
 - Couplet faulty-pixel correction
- Digital gain and white balance
- Programmable CFA interpolation that operates on a 5x5 grid
- Programmable RGB-to-RGB blending matrix: 9 coefficients for the 3x3 matrix
- Programmable gamma correction: 1024 entries for each color held in local memory
- Programmable RGB-to-YUV color conversion: 9 coefficients for the 3x3 matrix
- Luminance enhancement (nonlinear), chrominance suppression and offset

6.4.7.1.1 Camera ISP VPBE Preview Block Diagram

Figure 6-84 shows the preview engine block diagram.

Figure 6-84. Camera ISP VPBE Preview Engine Block Diagram

6.4.7.1.2 Camera ISP VPBE Preview Input Interface

The preview engine receives RAW image/video data from the video port interface through the CCDC or from the read buffer interface through the memory ([PRV_PCR \[2\] SOURCE](#)). When the source of input data is the CCDC, the input data is always 10 bits wide. When the source of input data is memory (read buffer interface), the data can be 8 or 10 bits wide. Use the [PRV_PCR\[4\] WIDTH](#) field to set the input data width. The 8 bits can be linear or nonlinear (A-Law compressed).

In addition, the preview engine can fetch a dark frame from memory, with each pixel 8 bits wide.

The frame-input size is configured using the [PRV_HORZ_INFO](#) and [PRV_VERT_INFO](#) registers.

If the input source is the CCDC, the input height set in the preview engine must be less than or equal to the output height of the video-port output of the CCDC. The input width must be at least 4 pixels smaller than the CCDC output width ($SPH = 2$; $EPH = 2$ pixels before the last pixel sent from the CCDC).

The input memory address ([PRV_RSDR_ADDR](#)) and line offset ([PRV_RADR_OFFSET](#)) registers should be aligned on 32-byte boundaries when the input source is set to memory. The dark-frame input address ([PRV_DSDR_ADDR](#)) and line offset ([PRV_DRKF_OFFSET](#)) should also be aligned on 32-byte boundaries when the dark-frame subtract function is enabled.

When the input source is memory, the preview engine always operates in one-shot mode. After enabling the preview engine and processing a frame, the enable bit is turned off and it is up to firmware to reenable it to process the next frame from memory.

When the input source is the CCDC, the preview engine can be configured to operate in one-shot mode or continuous mode ([PRV_PCR \[3\] ONESHOT](#)).

The SBL image data read port is shared between the preview and CSI1/CCP2B receiver module. When the image is read from memory, the read port must be affected to the preview receiver module by writing 0 into the [ISP_CTRL\[27\] SBL_SHARED_RPORTA](#). Programmers must ensure that the CSI1/CCP2B module does not use this port before switching to the preview module.

6.4.7.1.3 Camera ISP VPBE Preview Input Formatter/Averager

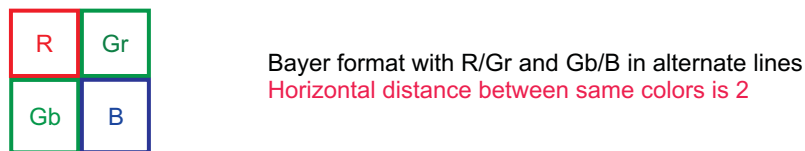

Preview-engine output is limited to 4096 pixels per horizontal line to support 12 Mpix, due to line memory-width restrictions in the noise filter and CFA interpolation blocks. To support sensors that output more than 4096 pixels per line, an averager is incorporated to downsample by factors of 1 (no averaging), 2, 4, or 8 in the horizontal direction ([PRV_AVE \[1:0\] COUNT](#)). The horizontal distance between two consecutive pixels of the same color to be averaged is selectable from among 1, 2, 3, or 4 for both even ([PRV_AVE \[3:2\] EVENDIST](#)) and odd ([PRV_AVE \[5:4\] ODDDIST](#)) lines. This must be configured to match the input pattern type.

For example, a Bayer pattern has a horizontal distance of two pixels of the same color for both even and odd lines.

Valid output of the input formatter/averager is either 8 or 10 bits wide.

[Figure 6-85](#) shows the horizontal distances for different patterns.

Figure 6-85. Camera ISP VPBE Preview Horizontal Distances for Different Patterns

camisp-308

6.4.7.1.4 Camera ISP VPBE Preview Dark-Frame Write

The preview engine is capable of capturing and saving a dark frame to memory instead of performing conventional processing steps ([PRV_PCR \[7\] DRKFCAP](#)).

This dark frame can later be subtracted from the RAW image data to eliminate the repeatable baseline noise level in the frame.

Each input pixel is written as an 8-bit value; if the input pixel value is greater than 255, it is saturated to 255. If a dark pixel is greater than 255, it is more likely to be faulty, and can be corrected by the faulty-pixel correction module in the CCDC. If properly corrected, the value must be less than 255 when it reaches the preview engine.

The [PRV_WSDR_ADDR](#) and [PRV_WADD_OFFSET](#) registers must be used to indicate the output address and line offset, respectively, of the dark-frame output in memory.

6.4.7.1.5 Camera ISP VPBE Preview Inverse A-Law

To save memory capacity and bandwidth, the CCDC includes an option to apply 10-bit to 8-bit A-Law compression and to pack the sensor data to 1 byte per pixel. To process this data correctly, the inverse A-Law block is provided to decompress the 8-bit nonlinear data back to 10-bit linear data if enabled ([PRV_PCR \[5\] INVALAW](#)). Even if the inverse A-Law block is not enabled, but the input is still 8 bits ([PRV_PCR \[4\] WIDTH](#)), the data is-left shifted by 2 to make it 10-bit data. If the input is 10 bits wide, no operation is performed on the data.

NOTE: When A-Law compression in CCDC is enabled during dark-frame write, it must be enabled when the stored dark frame is used.

6.4.7.1.6 Camera ISP VPBE Preview Dark-Frame Subtract or Shading Compensation

The preview engine can fetch a dark frame containing 8-bit values from memory (8 bits in input are converted internally to 10 bits by adding two zeros to the left) and subtracting it, pixel by pixel, from the incoming input frame ([PRV_PCR](#) [6] DRKFEN). This function removes pattern noise in the sensor. The output of the dark-frame subtract operation is 10 bits wide (U10Q0).

There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the [PRV_PCR](#) [31] DRK_FAIL status bit is set to indicate a fail.

Instead of performing the dark-frame subtract, the preview engine can perform lens-shading compensation (if [PRV_PCR](#) [21] SCOMP_EN is set along with [PRV_PCR](#) [6] DRKFEN). In this case, the 8-bit unsigned value fetched from memory is multiplied by the incoming pixel, and the result is right-shifted by the number of bits specified by the [PRV_PCR](#) [24:22] SCOMP_SFT parameter (0-7 bits).

The SBL data read port is shared between the CCDC and preview module. The read port must be affected to the preview module by writing 0 into the [ISP_CTRL](#) [28] SBL_SHARED_RPORTB. Programmers must ensure that the CCDC module does not use this port before switching to the preview module.

6.4.7.1.7 Camera ISP VPBE Preview Horizontal Median Filter

The preview engine contains a horizontal median filter that can help reduce temperature-induced noise effects. The input and output of the horizontal median filter are 10 bits wide (U10Q0).

NOTE: Line-width reduction: If the horizontal median filter is enabled, the preview engine reduces the length of the output line of this stage by 4 pixels (2 starting pixels -left edge and 2 ending pixels -right edge). For example, if the input size is 656 × 490 pixels, the output is 652 × 490 pixels. There is no truncation of input data line if this block is disabled.

6.4.7.1.8 Camera ISP VPBE Preview Noise Filter and Faulty Pixel Correction

The noise filter and couplet defect correction (CDC) operate on the same 33 matrix of same color pixels. Both functions can be enabled separately using the [PRV_PCR](#) [27] DCOREN and [PRV_PCR](#) [9] NFEN bits.

The faulty pixel correction function replaces the central pixel (x0) with one of the neighbors (x1-x8) in the following cases:

- When it has been identified as faulty.
- When the feature is enabled.

The noise filter modifies the central pixel when it is enabled.

NOTE: Some details of these features are not available in public domain

6.4.7.1.9 Camera ISP VPBE Preview White Balance

The white-balance module has a digital gain adjuster and a white-balance adjuster. In the digital gain adjuster ([PRV_WB_DGAIN](#) [9:0] DGAIN), RAW data is multiplied by a fixed-value gain, regardless of the color of the pixel to be processed.

In the white-balance gain adjuster ([PRV_WBGAIN](#)), RAW data is multiplied by a selected gain corresponding to the color of the processed pixel.

NOTE: Some details of this feature are not available in public domain

6.4.7.1.10 Camera ISP VPBE Preview CFA Interpolation

The CFA function is responsible for providing full RGB data for each pixel. Depending on sensor type and configuration, interpolation and/or rephasing are required.

The CFA function can be enabled ([PRV_PCR](#) [10] CFAEN) and configured to different interpolation modes ([PRV_PCR](#) [14:11] CFAFMT).

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.10.1 Camera ISP VPBE Preview CFA for Bayer Modes

In Bayer modes, the CFA interpolation block is responsible for populating the missing color pixels at a given location, resulting in a 3-color RGB pixel. It does this by interpolating data from neighboring pixels of the same color.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.10.2 Camera ISP VPBE Preview CFA Options

If the CFA interpolation block is disabled, the same input pixel is broadcast to all three output pixels.

NOTE: Image-size reduction: If CFA interpolation is enabled, the preview engine reduces the output of this stage. Two pixels/line in the left, right, top, and bottom edges are truncated in the Bayer/conventional and other modes.

If the CFA format is 2 downsampling in both horizontal and vertical directions, only 2 lines at the top and bottom of the image are truncated. The two left- and right-most pixels are processed.

6.4.7.1.11 Camera ISP VPBE Preview Black Adjustment

The CFA interpolation output is three pixels (red, blue, and green values) and this is fed as input to the black-adjustment module, which performs the following calculation for an adjustment of each color level:

$$data_out = data_in + bl_offset$$

The `bl_offset` values for each color are programmable in the [PRV_BLKADJOFF](#) register and coded in S8Q0 format (-128..+127). A simple one addition and clip operation are processed in this module. The output `data_out` [10..0] is signed.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.12 Camera ISP VPBE Preview RGB Blending

The RGB2RGB blending module has a general 3x3 square matrix and redefines the RGB data from the CFA interpolation module, which can be used as a function of a color correction. This is programmable ([PRV_RGB_MAT1](#), [PRV_RGB_MAT2](#), [PRV_RGB_MAT3](#), [PRV_RGB_MAT4](#), [PRV_RGB_MAT5](#), [PRV_RGB_OFF1](#), [PRV_RGB_OFF2](#)) so that the color spectrum of the sensor can be adjusted to the human color spectrum. The input is signed 11 bits and the output is unsigned 10 bits. The following calculation is performed in this module:

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} MTX_RR & MTX_GR & MTX_BR \\ MTX_RG & MTX_GG & MTX_BG \\ MTX_RB & MTX_GB & MTX_BB \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} MTX_OFFR \\ MTX_OFFG \\ MTX_OFFB \end{bmatrix}$$

camisp-E094

Gains are in S12Q8 format, and offsets are in S10Q0 format.

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

camisp-E161

That leads to:

$$\begin{aligned} MTX_RR &= MTX_GG = MTX_BB = 256 \\ others &= 0 \end{aligned}$$

camisp-E162

6.4.7.1.13 Camera ISP VPBE Preview Gamma Correction

Gamma correction is performed on each of the R, G, and B pixels separately by indexing programmable gamma look-up tables. Each table has 1024 8-bit entries. The input data value is used to index into the table and the table content is the output.

The gamma table can be bypassed ([PRV_PCR](#) [26] [GAMMA_BYPASS](#)). In this case, the output of the gamma correction is the 8 MSB of the 10-bit input. The gamma table can be written only while the preview engine is disabled.

6.4.7.1.14 Camera ISP VPBE Preview RGB to YCbCr Conversion, Luminance Enhancement, Chrominance Suppression, Contrast and Brightness, and 4:2:2 Downsampling and Output Clipping

6.4.7.1.14.1 RGB-to-YCbCr Conversion

The RGB-to-YCbCr conversion module has a 3x3 square matrix and converts the RGB color space of the image data into the YCbCr color space. In this module, the following calculation is performed using the contents of the [PRV_CSC0](#), [PRV_CSC1](#), [PRV_CSC2](#), and [PRV_CSC_OFFSET](#) registers:

$$\begin{bmatrix} Y \\ Cb \\ Cr \end{bmatrix} = \begin{bmatrix} CSCRY & CSCGY & CSCBY \\ CSCRCB & CSCGCB & CSCBCB \\ CSCRCR & CSCGCR & CSCBCR \end{bmatrix} \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} + \begin{bmatrix} YOFST \\ OFSTCB \\ OFSTCR \end{bmatrix}$$

camisp-E095

Gains are in S10Q8 format, and offsets are in S8Q0 format for chroma and U10Q0 for luma.

NOTE: Program the following values after reset for correct color conversion:

- [PRV_CSC2](#) [19:10] CSCGCR = 0x39E
 - [PRV_CSC2](#) [9:0] CSCRCR = 0x080
-

6.4.7.1.14.2 Nonlinear Luminance Enhancement

Nonlinear luminance enhancement functions as an edge enhancer (crossed in the horizontal direction). It can be enabled or disabled using the [PRV_PCR](#) [15] [YNENHEN](#) parameter. If it is enabled, a look-up table with 127 20-bit entries must be programmed. Each entry contains a 10-bit signed offset value in the MSBs, and a 10-bit signed slope in the LSBs.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.14.2.1 Chrominance Suppression

Occasionally, in very bright portions of an image, only one or two of the color channels are saturated, while the remaining channel(s) are not. This can lead to a false-color effect. One common example is the appearance of pink where white should be. Chrominance suppression can be used to correct this issue.

Chrominance suppression can be enabled or disabled using the [PRV_PCR](#) [16] SUPEN parameter.

NOTE: Some details of this feature are not available in the public domain.

6.4.7.1.14.2.2 Contrast and Brightness

The luminance component can be adjusted for contrast (scaling/multiplication) and brightness (offset/addition). Contrast is set in the [PRV_CNT_BRT](#) [15:8] CNT field (U8Q4 precision), and brightness is set in the [PRV_CNT_BRT](#) [7:0] BRT field (U8Q0 precision).

6.4.7.1.14.2.3 Downsampling and Output Clipping

The 4:2:2 conversion module converts image data to YCbCr-4:2:2 format by averaging every other Cb and Cr component in the horizontal direction. Before outputting the data, the preview engine performs clipping on the YCC components separately. The minimum and maximum threshold values for the Y and C values are specified using the [PRV_SETUP_YC](#) register. If no clipping is required, the register must be set to its reset values of 0xFF for the maximum Y and C values, and 0 for the minimum Y and C values.

6.4.7.1.15 Camera ISP VPBE Preview Write-Buffer Interface

The output of the preview engine may be passed directly to the Resizer ([PRV_PCR](#) [19] RSZPORT) and/or written to memory ([PRV_PCR](#) [20] SDRPORT).

If the output is written to memory, the write address ([PRV_WSDR_ADDR](#)) and line offset ([PRV_WADD_OFFSET](#)) must be on 32-byte boundaries. The output format of the YCC data is programmable by setting the [PRV_PCR](#) [18:17] YCPOS parameter.

The final width and height of the output vary depending on which processing functions are enabled. [Table 6-40](#) indicates how many edge pixels/lines are truncated by enabling certain modules in the preview engine. These values must be subtracted from the input height and width after the averager to determine the size of preview-engine output.

Table 6-40. Camera ISP VPBE Preview Image Cropping by Preview Functions

Image Cropping by Preview Functions		
Function	Pix/Line	Lines
Horizontal median filter	4	0
Noise filter	4	4
CFA (Bayer, Super CCD Honeycom or RGBE)	4	4
Color suppression OR luminance enhancement	2	0
Maximum total	14	8

NOTE: Different CFA modes are mutually exclusive.

6.4.7.2 Camera ISP VPBE Resizer

6.4.7.2.1 Camera ISP VPBE Resizer Features

The Resizer module enables image upsampling and downsampling, see [Table 6-41](#). The following features are supported:

- Flexible input sources:
 - Preview module: Enables on-the-fly processing

- Memory: Enables differenced processing
- Memory: CCDC module: Enables on-the-fly processing
- Flexible input format:
 - YUV422 packed data (16 bits)
 - Color-separate data (8 bits). The data must be contiguous in memory. The input source for the data must be the memory; not available for on-the-fly processing.
 - Same output format as input
- Upsampling: Up to 4. Enables digital zoom:
 - General polyphase filter:
 - Ratio of 1 to 4: 4 taps (horizontal and vertical) and 8 phases
- Downsampling: Down to 0.25:
 - General polyphase filter:
 - Ratio of 0.25 to 0.5: 7 taps (horizontal and vertical) and 4 phases
 - Ratio of 0.5 to 1: 4 taps (horizontal and vertical) and 8 phases
- Constraints:
 - The following input width (IW) and output width (OW) constraints must be obeyed due to limited on-chip memory resources.

Table 6-41. Camera ISP VPBE Resizer Use Constraints

Resizer Use Constraints			Horizontal Resizer Ratio	
			0.25 to 0.5	0.5 to 4
			7 taps	4 taps
Vertical Resizer ratio	0.25 to 0.5	7 taps	OW=2048	OW=2048
	0.5 to 4	4 taps	OW=4096	OW=4096

- The horizontal resizer output rate must not exceed half the functional clock; Moreover, the horizontal resizer output rate must not exceed 100M pixels/s. This limitation applies only for the on-the-fly processing input source.
- Flexible resizing ratios: Independent resizing factors for the horizontal and vertical directions. The applicable ratio is $256/N$, with N ranging from 64 to 1024.
- Programmable luminance enhancer
- Continuous and one-shot operation

6.4.7.2.2 Camera ISP VPBE Resizer Block Diagram

The resizer module performs either upsampling (digital zoom) or downsampling on image/video data within a range of 0.25 to 4 resizing. The input source can be sent to either the preview engine/CCDC or memory, and the output is sent to memory.

The resizer module performs horizontal resizing, then vertical resizing, independently. Between them there is an optional edge-enhancement feature. This process is shown in [Figure 6-86](#).

Figure 6-86. Camera ISP VPBE Resizer Process

camisp-063

6.4.7.2.3 Camera ISP VPBE Resizer Input and Output Interfaces

The input source can be sent to either the preview engine/CCDC or memory ([RSZ_CNT](#) [28] INPSRC). The input width ([RSZ_IN_SIZE](#) [12:0] HORZ) must be at least 32 pixels.

6.4.7.2.3.1 Camera ISP VPBE Resizer Preview Engine/CCDC Input Mode

In the preview engine/CCDC input mode, internal hardware synchronization signals define input frames. The horizontal starting byte ([RSZ_IN_START](#) [12:0] HORZ_ST) and vertical starting line ([RSZ_IN_START](#) [28:16] VERT_ST) define a starting pixel with respect to the upper-left corner of an input image (signaled through horizontal and vertical synchronization signals). The input width and height in the [RSZ_IN_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

NOTE: Care must be taken to ensure that the input sizes specified by the [RSZ_IN_START](#) and [RSZ_IN_SIZE](#) registers are less than or equal to the output from the preview engine or CCDC; otherwise, incorrect hardware operation may occur.

[RSZ_SDR_INADD](#) and [RSZ_SDR_INOFF](#) must be programmed to be 0x0 in this mode.

Also, the output ports of the CCDC ([CCDC_SYN_MODE](#) [19] SDR2RSZ) and preview engine ([PRV_PCR](#) [19] RSZPORT) to the resizer must be configured so that only one of them is enabled. If both are enabled, the CCDC gains control of this interface.

If input is from the CCDC, the output of the CCDC must be in YUV422 format (the resizer does not support resizing RAW data from the CCDC).

6.4.7.2.3.2 Camera ISP VPBE Resizer Memory-Input Mode

In memory-input mode, the memory address in [RSZ_SDR_INADD](#) points to the 32-byte-aligned memory address where the starting pixel resides.

The horizontal starting pixel ([RSZ_IN_START](#) [12:0] HORZ_ST) defines a starting pixel within that 32-byte alignment; HORZ_ST is constrained to 0...15 for the YUV 422 format, and 0...31 for the color-separated format.

The vertical starting pixel ([RSZ_IN_START](#) [28:16] VERT_ST) must be zero in memory-input mode. The [RSZ_SDR_INOFF](#) register specifies the address offset between rows of input data. The input width and height in the [RSZ_IN_SIZE](#) register specify the exact input range (relative to the starting pixel) necessary to generate an output frame of specified width/height.

Figure 6-87 shows the resizer in memory-input mode.

Figure 6-87. Camera ISP VPBE Resizer Resizer in Memory-Input Mode

camisp-115

6.4.7.2.3.3 Camera ISP VPBE Resizer Output Interface

In both input modes, the [RSZ_OUT_SIZE](#) register specifies output width/height, the [RSZ_SDR_OUTADD](#) register specifies output starting pixel (upper-left corner) memory address, and the [RSZ_SDR_OUTOFF](#) register specifies memory address offset between the beginning of output rows. The resizer output always goes to memory.

NOTE: [RSZ_SDR_INADD](#), [RSZ_SDR_OUTADD](#), [RSZ_SDR_INOFF](#), and [RSZ_SDR_OUTOFF](#) must be 32-byte-aligned; the lower 5 bits of the byte address are assumed to be zero.

Output-width constraints: The output width ([RSZ_OUT_SIZE](#) [11:0] HORZ) must be at least 16 pixels, and be even (so that the same number of Cb and Cr components is outputted). Due to the vertical memory size constraint, the output width ([RSZ_OUT_SIZE](#) [11:0] HORZ) cannot be greater than:

- 4096 pixels if the vertical resizing ratio is between 1/2 and 4 (([RSZ_CNT](#) [19:10] VRSZ + 1) = 512)
- 1650 pixels wide if the vertical resizing ratio is between 1/2 and 1/4 (([RSZ_CNT](#) [19:10] VRSZ + 1) 512)

6.4.7.2.4 Camera ISP VPBE Resizer Horizontal and Vertical Resizing

In the rest of this section:

- HRSZ is used for [RSZ_CNT](#) [9:0] HRSZ + 1.
- VRSZ is used for [RSZ_CNT](#) [19:10] VRSZ + 1.

The resizer module can upsample or downsample image data with independent resizing factors in the horizontal and vertical directions. The HRSZ and VRSZ parameters can range from 64 to 1024 to give a resampling range from 4 to 0.25 (256/HRSZ or 256/VRSZ).

The resizer module uses the same resampling algorithm for the horizontal and vertical directions.

The resizing/resampling algorithm uses a programmable polyphase sample rate converter (resampler). The polyphase filter coefficients are programmable so that any user-specified filter can be implemented.

Figure 6-88 shows a general sample-rate converter where the resampling rate is equal to L/M.

Figure 6-88. Camera ISP VPBE Resizer Typical Sample-Rate Converter

L phases are used in a typical polyphase implementation. The resizer module, however, fixes the number of phases to 8 for a resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 4 for a resizing range of 1/4 ~ 1/2 (RSZ = 513 ~ 1024). In this way, the upsampling value (L) is fixed to either 8 or 4, and the downsampling value (M) is based on RSZ. To achieve a resizing ratio of 256/RSZ, the downsampling value (M) is equal to (P×RSZ)/256, where P is the number of phases. Figure 6-89 shows the resizer functionality.

Figure 6-89. Camera ISP VPBE Resizer Functionality

Figure 6-90 shows a model of the resolution of the noninteger downsampling ratio. The interpolated output from the filter is upsampled and replicated 256/P times before it is downsampled by the RSZ factor.

Figure 6-90. Camera ISP VPBE Resizer Approximation Scheme

This implementation means that a resizing ratio with 256/RSZ times the input size can be obtained. However, each output pixel is rounded to the nearest interpolated output of 1/P input-pixel precision. The polyphase filter coefficients are programmable so that any user-specified filter can be implemented. It is recommended that coefficient sets be chosen to implement a sample rate converter where a low-pass filter is used, with a cutoff frequency as shown in Figure 6-91.

Figure 6-91. Camera ISP VPBE Resizer Cutoff Frequency for Low-Pass Filter

$$\omega_c = \min\left(\frac{\pi}{P}, \frac{\pi}{\left(\frac{P \times RSZ}{256}\right)}\right)$$

camisp-E126

If polyphase resampling is used, all upsampling factors can share the same set of coefficients. However, a different coefficient set is required when changing between 8-phase and 4-phase modes, and with different downsampling factors.

32 programmable coefficients are available for the horizontal direction (registers [RSZ_HFILT10](#) to [RSZ_HFILT3130](#)) and another 32 programmable coefficients are available for the vertical direction (registers [RSZ_VFILT10](#) to [RSZ_VFILT3130](#)). The 32 programmable coefficients are arranged as either 4 taps and 8 phases for the resizing range of 1/2 ~ 4 (RSZ = 64 ~ 512), or 7 taps and 4 phases for a resizing range of 1/4 ~ 1/2 (RSZ = 513 ~ 1024)(RSZ is either HRSZ or VRSZ). [Table 6-42](#) shows the arrangement of the 32 filter coefficients. Each tap is arranged in S10Q8 format.

Table 6-42. Camera ISP VPBE Resizer Arrangement of the Filter Coefficients

Filter Coefficient	0.5x to 4x		0.24x to ~0.5x		
	Phase	Tap	Phase	Tap	
0	0	0	0	0	
1		1		1	
2		2		2	
3		3		3	
4	1	0		4	
5		1		5	
6		2		6	
7		3	Not used		
8	2	0	1	0	
9		1		1	
10		2		2	
11		3		3	
12	3	0		4	
13		1		5	
14		2		6	
15		3	Not used		
16	4	0			
17		1			
18		2			
19		3			
20	5	0			
21		1			
22		2			
23		3	Not used		
24	6	0	3		0
25		1			1
26		2			2
27		3		3	
28	7	0		4	
29		1		5	
30		2		6	
31		3	Not used		

The indexing scheme of coefficients is oriented for dot-product (or inner product), rather than for impulse response. In other words, the first data point contributing to a particular output is multiplied by the coefficient associated with tap 0, and the last data point is multiplied by the coefficient associated with tap 3 or tap 6 (depending on whether it is 4-tap or 7-tap mode). The normal raster-scan order is used where the upper-left corner gets the (0, 0) coordinate. Pixel 0 is the left-most column of pixels for horizontal resizing, and the top-most row of pixels for vertical resizing. [Figure 6-92](#) shows an example of the alignment of input pixels to tap coefficients using a simple 1:1 resize case (4-tap mode). In this example, only one phase output is necessary.

[Figure 6-92](#) shows the alignment of input pixels to tap coefficients.

Figure 6-92. Camera ISP VPBE Resizer Alignment of Input Pixels to Tap Coefficients

camisp-116

Figure 6-92 also shows how the first output is computed when all taps are aligned with input pixels. To compute the last several pixels in each line/column, the filter requires more input pixels than the following equation calculates:

$$\text{input size} = \text{output size} * \text{RSZ} / 256$$

In the former example, where the input size is X and the output size is Y, three extra input pixels are required to generate the correct number of output pixels:

$$X = Y * 256 / 256 + 3 \text{ (to account for the extra pixels required for filtering)}$$

The input size calculation depends on the starting phase and rounding issues in the algorithm. Table 6-43 lists the input size calculations derived from the algorithm description in Section 6.4.7.2.5. The input width and height parameters must be programmed strictly according to these equations; otherwise, incorrect hardware operation may occur.

Table 6-43. Camera ISP VPBE Resizer Input Size Calculations

	8-Phase, 4-Tap Mode	4-Phase, 7-Tap Mode
RSZ_IN_SIZE[12:0] HORZ	$(32 * \text{sph} + (\text{ow} - 1) * \text{hrsz} + 16) 8 + 7$	$(64 * \text{sph} + (\text{ow} - 1) * \text{hrsz} + 32) 8 + 7$
RSZ_IN_SIZE[28:16] VERT	$(32 * \text{spv} + (\text{oh} - 1) * \text{vrsz} + 16) 8 + 4$	$(64 * \text{spv} + (\text{oh} - 1) * \text{vrsz} + 32) 8 + 7$

Where:

sph = Start phase horizontal (**RSZ_CNT** [22:20] HSTPH)

spv = Start phase vertical (**RSZ_CNT** [25:23] VSTPH)

ow = Output width (**RSZ_OUT_SIZE** [11:0] HORZ + extra)

oh = Output height (**RSZ_OUT_SIZE** [27:16] VERT)

hrsz = Horizontal resize value (**RSZ_CNT** [9:0] HRSZ + 1)

vrsz = Vertical resize value (**RSZ_CNT** [19:10] VRSZ + 1)

extra = 0 when **RSZ_YENH** [17:16] ALGO = 0 (edge enhancement disabled)

extra = 4 when **RSZ_YENH** [17:16] ALGO != 0 (edge enhancement enabled)

The horizontal and vertical starting phases can be programmed in the [RSZ_CNT \[22:20\]](#) HSTPH and [RSZ_CNT \[25:23\]](#) VSTPH fields, respectively. The chrominance data can be resized using bilinear interpolation or the same algorithm as the luminance data ([RSZ_CNT \[29\]](#) CBILIN).

The following section explains how these fields are used in the algorithm.

6.4.7.2.5 Camera ISP VPBE Resizer Resampling Algorithm

The resizer module uses the same resampling algorithm for the horizontal and vertical directions. For the rest of this section, the horizontal direction is used in describing the resampling algorithm. The algorithm is described first for the 4-tap/8-phase mode, then for the 7-tap/4-phase mode.

[Section 6.4.7.2.5.1](#) and [Section 6.4.7.2.5.2](#) explain the generic algorithm without detailing the differences between color components. [Section 6.4.7.2.5.3](#) describes how interleaved chroma are processed when input is YUV422.

6.4.7.2.5.1 Camera ISP VPBE Resizer 4-Tap/8-Phase Mode

In the 4-tap/8-phase mode, the coefficients for each of the 8 phases may be set to interpolate 8 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/256 input-pixel precision is incremented by the [RSZ_CNT \[9:0\]](#) HRSZ +1 value. A coarse-input pointer with 1/8 input-pixel precision (corresponds to one of the 8 phases) is calculated by rounding the fine-input pointer to the nearest 1/8 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate four input pixels. [Figure 6-93](#) shows a pseudo-code description of the resizer algorithm in the 4-tap/8-phase mode.

Figure 6-93. Camera ISP VPBE Resizer Pseudo-Code Description of the Resizer Algorithm in the 4-Tap/8-Phase Mode

- The starting input pixel location (in whole pixels) (see [Section 6.4.7.2.3, Camera ISP VPBE Resizer Input and Output Interfaces](#)) and the starting phase (in 1/8 pixel) ([RSZ_CNT \[22:20\]](#) HSTPH) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256-pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output, based on the fine-input pointer.
- The coarse-input pointer is in 1/8 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256* starting input pixel + 32* starting phase - 256. The fine-input pointer defines the starting 1/8 pixel location covered by the filter waveform.
- For each output pixel:

Coarse-input pointer = (fine-input pointer + 16) 5 /* Rounded to the nearest phase */

Pixel-input pointer = (coarse-input pointer 3) + 1 /* Rounded up to a whole pixel, when already on an integer pixel, go to next one to simplify coefficient organization */

Coefficient phase = (coarse-input pointer 7) /* 3 LSBs = phase */

Output = dot product of the 4 coefficients and the 4 inputs starting with pixel-input pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma

```

fine-input pointer = fine-input pointer
+ (RSZ_CNT [9:0] HRSZ + 1)
/* distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1) /256 = (RSZ_CNT
[9:0] HRSZ + 1) in 1/256 precision */

```

- Same algorithm in the horizontal and vertical directions, except with separate initial pixel/phase values and separate RSZ values.

6.4.7.2.5.2 Camera ISP VPBE Resizer 7-Tap/4-Phase Mode

In the 7-tap/4-phase mode, the coefficients for each of the 4 phases may be set to interpolate 4 intermediate pixels between input pixels. For each output pixel calculation, a fine-input pointer with 1/56 input-pixel precision is incremented by the `RSZ_CNT [9:0] HRSZ + 1` value. A coarse-input pointer with 1/2 input-pixel precision (corresponds to one of the 4 phases) is calculated by rounding the fine-input pointer to the nearest 1/2 pixel. The output pixel is calculated by the dot product of the coefficients of the phase filter (selected by the coarse-input pointer) and the appropriate 7 input pixels. Figure 6-94 shows a pseudo-code description of the resizer algorithm in the 7-tap/4-phase mode.

Figure 6-94. Camera ISP VPBE Resizer Pseudo-Code Description of the Resizer Algorithm in the 7-Tap/4-Phase Mode

- The starting input-pixel location (in whole pixels) (see Section 6.4.7.2.3, *Camera ISP VPBE Resizer Input and Output Interfaces*) and the starting phase (in 1/2 pixel) (`RSZ_CNT [22:20] HSTPH`) are programmed through the resizer registers.
- A fine-input pointer is maintained in 1/256 pixel precision.
- A coarse-input pointer and a pixel-input pointer are computed for each output based on the fine-input pointer.
- The coarse-input pointer is in 1/2 pixel precision. The pixel-input pointer is in whole-pixel precision.
- Initially, fine-input pointer = 256 * starting input pixel + 64 * starting phase - 256. The fine-input pointer defines the starting 1/2 pixel location covered by the filter waveform.
- For each output pixel:

```

Coarse-input pointer = (fine-          /* Round to the nearest phase */
input pointer + 32) 6
Pixel-input pointer = (coarse-        /* Round up to a whole pixel; when already on an
input pointer 2) + 1                integer pixel, go to next one to simplify coefficient
                                     organization */
Coefficient phase = (coarse-         /* 2 LSBs = phase */
input pointer 3)
Output = Dot product of the 7 coefficients and the 7 inputs starting with the pixel-input
pointer
Clip output to 8-bit unsigned for luma, 8-bit signed for chroma
/* It is acceptable to require the 8th coefficients to be filled with zeros by firmware so that 8
coefficients and 8 inputs, the last input being don't care value, are multiply-added */
Fine-input pointer = Fine input pointer + (RSZ_CNT [9:0] HRSZ + 1)
/* Distance between outputs = 1/resize_factor = (RSZ_CNT [9:0] HRSZ + 1)/256 =
(RSZ_CNT [9:0] HRSZ + 1) in 1/256 precision */

```

- Same algorithm in both the horizontal and vertical directions, but with separate initial pixel/phase values and separate RSZ values.

NOTE: The pixel-input pointer (pip) in the algorithm description, points to pixels, not bytes or shorts in the memory. The fine-input pointer (fip) points to a 1/256 resolution sub-pixel position. The coarse-input point (cip) points to a 1/8 or 1/4 resolution sub-pixel location, depending on the number of phases.

6.4.7.2.5.3 Camera ISP VPBE Resizer Horizontal Resizing With Interleaved Chroma

Chroma inputs, Cb and Cr, are 8-bit unsigned values that represent 128-biased 8-bit signed values (the signed chroma are called U and V instead of Cb and Cr). During the resizing computation, the chroma values have the 128 bias subtracted to convert to the 8-bit signed format. After vertical resizing, the 128 bias is added back to convert back to 8-bit unsigned format.

Chroma components, which are 2:1 horizontally downsampled with respect to luma, have two methods of horizontal resizing processing: filtering with luma, and bilinear interpolation.

The horizontal resizing with interleaved chroma option can be selected in the [RSZ_CNT](#) [29] CBILIN field independently of the [RSZ_CNT](#) [22:20] HSTPH parameters. However, filtering with luma is intended only for downsampling, and bilinear interpolation is intended only for upsampling.

For horizontal resizing of Y/Cb/Cr in a combined filtering flow, the algorithm is modified as shown in the following algorithm descriptions:

Filter Chroma With Luma (4-Tap/8-Phase Mode):

```

For (i=0; ioutput_width; i++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 16) 5      /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer 3) + 1     /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer 7             /* 3 LSB = phase */
    if (i 1 == 0) { /* even output pixel, generate YCbCr */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 4 coefficients and the 4 upsampled Cb inputs starting with pixel-
            input pointer
        Crout = dot product of the 4 coefficients and the 4 upsampled Cr inputs starting with pixel-
            input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
            signed for chroma
    }
    Else /* odd output pixel, generate Y only */
        Yout = dot product of the 4 coefficients and the 4 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }
    Fine-input pointer = fine-input pointer + (RSZ\_CNT [9:0] HRSZ + 1)
}
}

```

Filter Chroma With Luma (7-Tap/4-Phase Mode):

```

For (i=0; ioutput_width; i++) { /* output width depends of input width and resizing factors*/
    Coarse-input pointer = (fine-input pointer + 32) 5      /* Round to nearest phase */
    Pixel-input pointer = (coarse-input pointer 2) + 1    /* Round up to a whole pixel */
    Coefficient phase = pixel-input pointer 3            /* 2 LSB = phase */
    if (i 1 == 0) { /* Even output pixel, generate YCbCr */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Cbout = dot product of the 7 coefficients and the 7 upsampled Cb inputs starting with pixel-
        input pointer
        Crout = dot product of the 7 coefficients and the 7 upsampled Cr inputs starting with pixel-
        input pointer
        Clip outputs to 8-bit unsigned for luma, 8-bit
        signed for chroma
    }
    Else { /* Odd output pixel, generate Y only */
        Yout = dot product of the 7 coefficients and the 7 Y inputs starting with pixel-input pointer
        Clip output to 8-bit unsigned
    }
    Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
}
}

```

NOTE: The chroma input values are internally replicated to realize 1:2 upsampling to line up with luma input values. Only required chroma outputs are computed; they correspond to even luma outputs.

Bilinear Interpolation (4-Tap or 7-Tap):

For the bilinear interpolation flow of chroma horizontal resizing, the algorithm is adapted as follows. For the bilinear interpolation option, it is not necessary to replicate chroma samples.

```

For (i=0; ioutput_width; i++) {
    if (i 1 == 0) { /* even output pixel, generate YCbCr */
        Coarse-input pointer = ... /*Calculation issued from 4 taps or 7
        taps*/
        Pixel-input pointer = ... /*Calculation issued from 4 taps or 7 taps*/
        Yout = dot product of ... /*Calculation issued from 4 taps or 7
        taps*/
        C_fine_input_pointer = fine_input_pointer + 128*ntaps          /* Points to center of filter
        kernel */
        Cidx = C_fine_input_pointer 9                                  /* Truncate to even pixel
        grid to find left value */

        Cbin[0] = Cb[Cidx]
        Cbin[1] = Cb[Cidx + 1]
        Crin[0] = Cr[Cidx]
        Crin[1] = Cr[Cidx + 1]
        frac = C_fine_input_pointer 511                              /* 9-bit fraction */
        Cbout = ((512 - frac) * Cbin[0] + frac * Cbin[1] + 256) 9
        Crout = ((512 - frac) * Crin[0] + frac * Crin[1] + 256) 9
        Clip outputs to 8-bit unsigned for luma, 8-bit signed for chroma
    }
}

```

```

        Fine-input pointer = fine-input pointer + (RSZ_CNT [9:0] HRSZ + 1)
    }
    Else { /* odd output pixel, generate Y only */
        . . .
    }
}

```

In the former algorithm, fixed-point arithmetic is used. The variable *frac* is an unsigned integer representing the fraction *f*. Thus, 1- *f* becomes 512 - *frac*. After the sum of products, 256, representing 0.5 real-numbers, is added to the sum, and then the sum is right-shifted by 9 bits to get back to the integer chroma representation.

In both algorithm options, the chroma outputs computed are interleaved with luma values to generate the YCbYCr output format (or the alternate format specified in [RSZ_CNT](#) [26] YCPOS).

In the vertical resizing stage, the two chroma planes are processed interleaved as one separate image. Because there is no resolution issue vertically, and no horizontal dependency in vertical resizing, the vertical scheme is consistent with conventional processing, and is not analyzed here.

6.4.7.2.5.4 Camera ISP VPBE Resizer Algorithm Functionality

[Table 6-44](#) is an example of 1:2.56 (*hrsz* = 100) horizontal resizing that illustrates the address calculation and chroma processing in 4:2:2 format (4-tap 8-phase mode). The starting pixel and phase are assumed to be zero.

Table 6-44. Camera ISP VPBE Resizer Processing Example for 1:2.56 Horizontal Resize

Output	Y0	Cb0	Cr0	Y1	Y2	Cb2	Cr2	Y3	Y4	Cb4	Cr4	Y5

Inputs needed for chroma bilinear interpolation		Cb0	Cr0			Cb0	Cr0			Cb2	Cr2	
		Cb2	Cr2			Cb2	Cr2			Cb4	Cr4	

Note the distinction between using {Cb0, Cb0, Cb2, Cb2} and {Cb0, Cb2, Cb2, Cb4} as input to the filter. The 4 filter taps are applied in order, so with the different chroma component repetition, the result is different (even when the coefficient phase is the same).

The *Cidx* of the chroma bilinear interpolation flow points to the chroma sample in linear array order, so *Cidx* = 1 means we Cb2 and Cb4 are being grabbed.

6.4.7.2.6 Camera ISP VPBE Resizer Luma Edge Enhancement

Edge enhancement can be applied to the horizontally resized luminance component before the output of the horizontal stage is sent to the line memories and the vertical stage. The [RSZ_YENH](#) [17:16] ALGO parameter can be set to disable edge enhancement, or to select a 3-tap or a 5-tap horizontal high-pass filter (HPF) for luminance enhancement. The edge enhancement algorithm is as follows:

If edge enhancement is selected, the two left-most and two right-most pixels in each line are not outputted to the line memories and the vertical stage. The [RSZ_OUT_SIZE](#) [11:0] HORZ register is the final output width, up to 1280 pixels when vertical 4-tap mode is used, and up to 640 pixels when vertical 7-tap mode is used. When edge enhancement is enabled, the horizontal resizer output width used to calculate the required input width must be [RSZ_OUT_SIZE](#) [11:0] HORZ + 4.

NOTE: Some details of this feature are not available in the public domain,

[RSZ_YENH](#) [7:0] CORE is in U8Q0. [RSZ_YENH](#) [11:8] SLOP is in U4Q4. [RSZ_YENH](#) [15:12] GAIN is in U4Q4.

6.4.8 Camera ISP Statistics Collection Modules

The statistics-collection modules (SCMs) are the H3A and histogram modules that provide statistics on the incoming images to help designers of camera systems.

6.4.8.1 Camera ISP H3A

6.4.8.1.1 Camera ISP H3A Features

The H3A module supports control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus engine (AF):
 - The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a two-dimensional block of data referred to as a paxel. The AF engine supports the following features:
 - Peak mode in a paxel (a paxel is defined as a two dimensional block of pixels): Accumulate the maximum focus value of each line in a paxel.
 - Accumulation of the maximum focus value of each line in a paxel
 - Accumulation mode
 - Accumulation/sum mode (instead of peak mode): Accumulation of focus value in a paxel
 - Up to 36 paxels/windows in the horizontal direction and up to 128 paxels/windows in the vertical direction
 - Programmable width and height for the paxel/window
 - Programmable red, green, and blue position within a 2x2 matrix
 - Separate horizontal start for paxel and filtering
 - Programmable vertical line increments within a paxel
 - Parallel IIR filters configured in a dual-biquad configuration with individual coefficients (2 filters with 11 coefficients each)
- Auto exposure and auto white balance engine (AE/AWB)
 - The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the two-dimensional block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:
 - Accumulation of clipped pixels along with all nonsaturated pixels
 - Up to 36 horizontal windows/paxel and up to 128 vertical windows/paxel
 - Separate vertical start coordination and height for a black row of paxels different from the remaining color paxels
 - Programmable horizontal and vertical sampling points in a window

NOTE: Some details of this feature are not available in the public domain.

6.4.8.1.2 Camera ISP H3A Autofocus Engine

The autofocus engine works by extracting each red, green, and blue pixel from the video stream and subtracting a fixed offset from the pixel value (128 when A-Law is enabled or 512 when A-Law is disabled). The offset value is then passed through two IIR filters, and the absolute values of the filter outputs are the focus values (FV). For each pixel, the pixel values and the two focus value outputs are accumulated for each color and sent to memory. The following sections describe this process in more detail.

Only RAW10 data is supported by the autofocus function. In some cases, RAW8 or RAW12 data can be converted to RAW10 using the data-lane shifter.

6.4.8.1.3 Camera ISP H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows and further subsampling each window into 2x2 blocks. Then, for each subsampled 2x2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2x2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

6.4.8.2 Camera ISP Histogram

6.4.8.2.1 Camera ISP Histogram Features

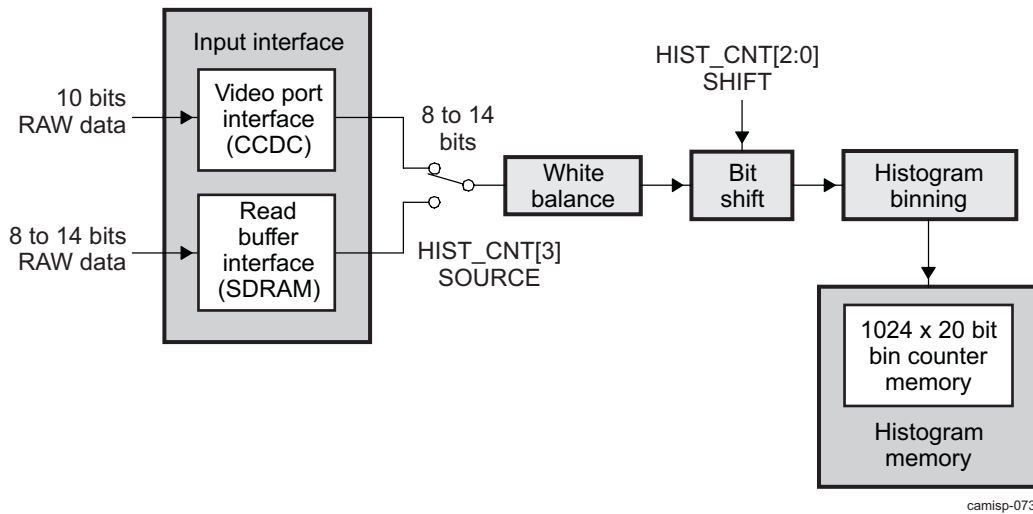

The histogram accepts RAW image/video data from either the video-port interface of the CCDC or from memory, performs a color-separate gain on each pixel (white/channel balance), and bins the pixels according to the amplitude, color, and region specified through the CCDC register settings. It can support 4 colors (Bayer), and up to 4 regions, simultaneously. [Figure 6-95](#) shows the processing of the histogram module.

The histogram module is typically used with 3A metrics by the host processor to adjust various parameters for processing image data. The following features are supported:

- Flexible input: Input data can come from the RAW image sensor (through the CCDC module) or from memory.
- Color-separate gain: A digital gain per color component can be applied before histogram computation.
- Histogram computation: The module performs pixel binning of the incoming RAW image data. Each bin collects the number of pixels with values in a range. If no saturation occurs, the sum of the values in every bin is equal to the total number of pixels in the input image. The histogram computation can occur over one frame or be accumulated over multiple frames. The computation occurs on rectangular regions. A histogram is computed for each color component in the image:
 - The RAW image data dynamic can be up to 10 bits (pixel values in the range 0 to 1023).
 - Range: Each bin covers a pixel range. Each bin can cover a maximum of 128 pixel values.
 - Programmable regions: There can be up to four regions. The region positions and horizontal and vertical sizes are programmable. When regions overlap, pixels from the overlapped area are accumulated into the highest-priority region only; region0 has the highest priority and region3 the lowest priority.
 - Programmable number of bins: There can be 32, 64, 128, or 256 bins per color and per region. The number of bins depends on the number of regions, because histogram memory size is fixed.
 - Color components: A histogram is computed for each color component in the RAW image. There are usually 4 color components in Bayer image sensors.
- Saturation: If the pixel count exceeds $2^{20}-1$, the pixel count is saturated.
- Memory clear: The histogram memory is cleared automatically when it is read.
- Output: The histogram result is stored in a local RAM read by a system initiator, typically the system DMA, to be written to memory.

6.4.8.2.2 Camera ISP Histogram Block Diagram

Figure 6-95. Camera ISP Histogram Process

6.4.8.2.3 Camera ISP Histogram Input Interface

The histogram receives RAW image/video data from the video port interface through the CCDC (which is interfaced to an external sensor) or from the read buffer interface through memory ([HIST_CNT \[3\] SOURCE](#)).

The input data is 10 bits wide if the source is the video-port interface. When the input source is from memory, data-bit width can range from 8 to 14 bits. If the input data is 8 bits packed (memory contains two 8-bit pixels for every 16 bits), the [HIST_CNT \[8\] DATSIZ](#) bit must be set. If memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared.

Likewise, if memory contains one pixel for every 16 bits, the DATSIZ bit must be cleared. The input memory address ([HIST_RADD](#)) and line-offset ([HIST_RADD_OFF](#)) registers are used to specify the location of the input frame in memory. Both of these registers should be aligned on 32-byte boundaries.

The frame-input width and height are configured using the [HIST_H_V_INFO \[29:16\] HSIZE](#) and [HIST_H_V_INFO \[13:0\] VSIZE](#) register fields, respectively.

The histogram module supports 4-color Bayer color patterns. The [HIST_CNT \[6\] CFA](#) field is used to select the color pattern of the input data (Bayer).

6.4.8.2.4 Camera ISP Histogram White Balance

A white-balance gain can be separately applied to each color channel by programming the fields in the [HIST_WB_GAIN](#) register. [Table 6-45](#) indicates which pixel index in the color pattern corresponds to each field in the WB_GAIN register.

Table 6-45. Camera ISP Histogram White Balance Field-to-Pattern Assignments

HIST_WB_GAIN fields	Bayer
WG00	0
WG01	1
WG02	2
WG03	3

NOTE: There are four different physical locations, with one color per location for Bayer. See [Figure 6-96](#).

Figure 6-96. Camera ISP Histogram Color Pattern Index

Bayer	
0	1
2	3

camisp-309

Each gain constant is 8 bits wide with 5 bits of decimal precision (U8Q5).

6.4.8.2.5 Camera ISP Histogram Binning

The histogram bins the input data by amplitude, color, and region (see [Figure 6-97](#)). Each bin is a counter, counting the number of pixels of a color in the range associated with the bin. The number of bins can be programmed to 32, 64, 128, or 256 bins in the `HIST_CNT` [5:4] BINS field. However, due to limited histogram memory size (1024 words), the number of bins (times 4 colors) limits the number of regions that can be active, as shown in [Table 6-46](#).

Table 6-46. Camera ISP Histogram Regions and Bins

Number of Bins	Number of Regions Allowed
256	1
128	2
64	4
32	4

As indicated by [Table 6-46](#), up to four overlapping regions can be designated within the frame. Each region is defined by the horizontal starting (`HIST_Rn_HORZ` [29:16] HSTART) and ending (`HIST_Rn_HORZ` [13:0] HEND) pixels, and the vertical starting (`HIST_Rn_VERT` [29:16] VSTART) and ending (`HIST_Rn_VERT` [13:0] VEND) lines (where n is the region number 0...3).

NOTE: If the starting and ending pixels/lines are the same, the region size is treated as zero, and there is no binning for such a region.

6.4.8.2.5.1 Camera ISP Histogram Region Priority

Up to four regions can be active at any time, but a pixel is binned into only one region. The priority is Region 0 Region 1 Region 2 Region 3. For example, the yellow pixel in [Figure 6-97](#) is binned only for Region 0, although it is present in all four regions.

Figure 6-97. Camera ISP Histogram Region Priority

6.4.9 Camera ISP Central-Resource Shared Buffer Logic

The central-resource shared buffer logic (SBL) receives data read and write requests from the CCDC, preview, H3A, histogram, resizer, CSI2A, CSI2C, and CSI1/CCP2B modules. It arbitrates between requesters and constructs bursts to transfer data to and from memory.

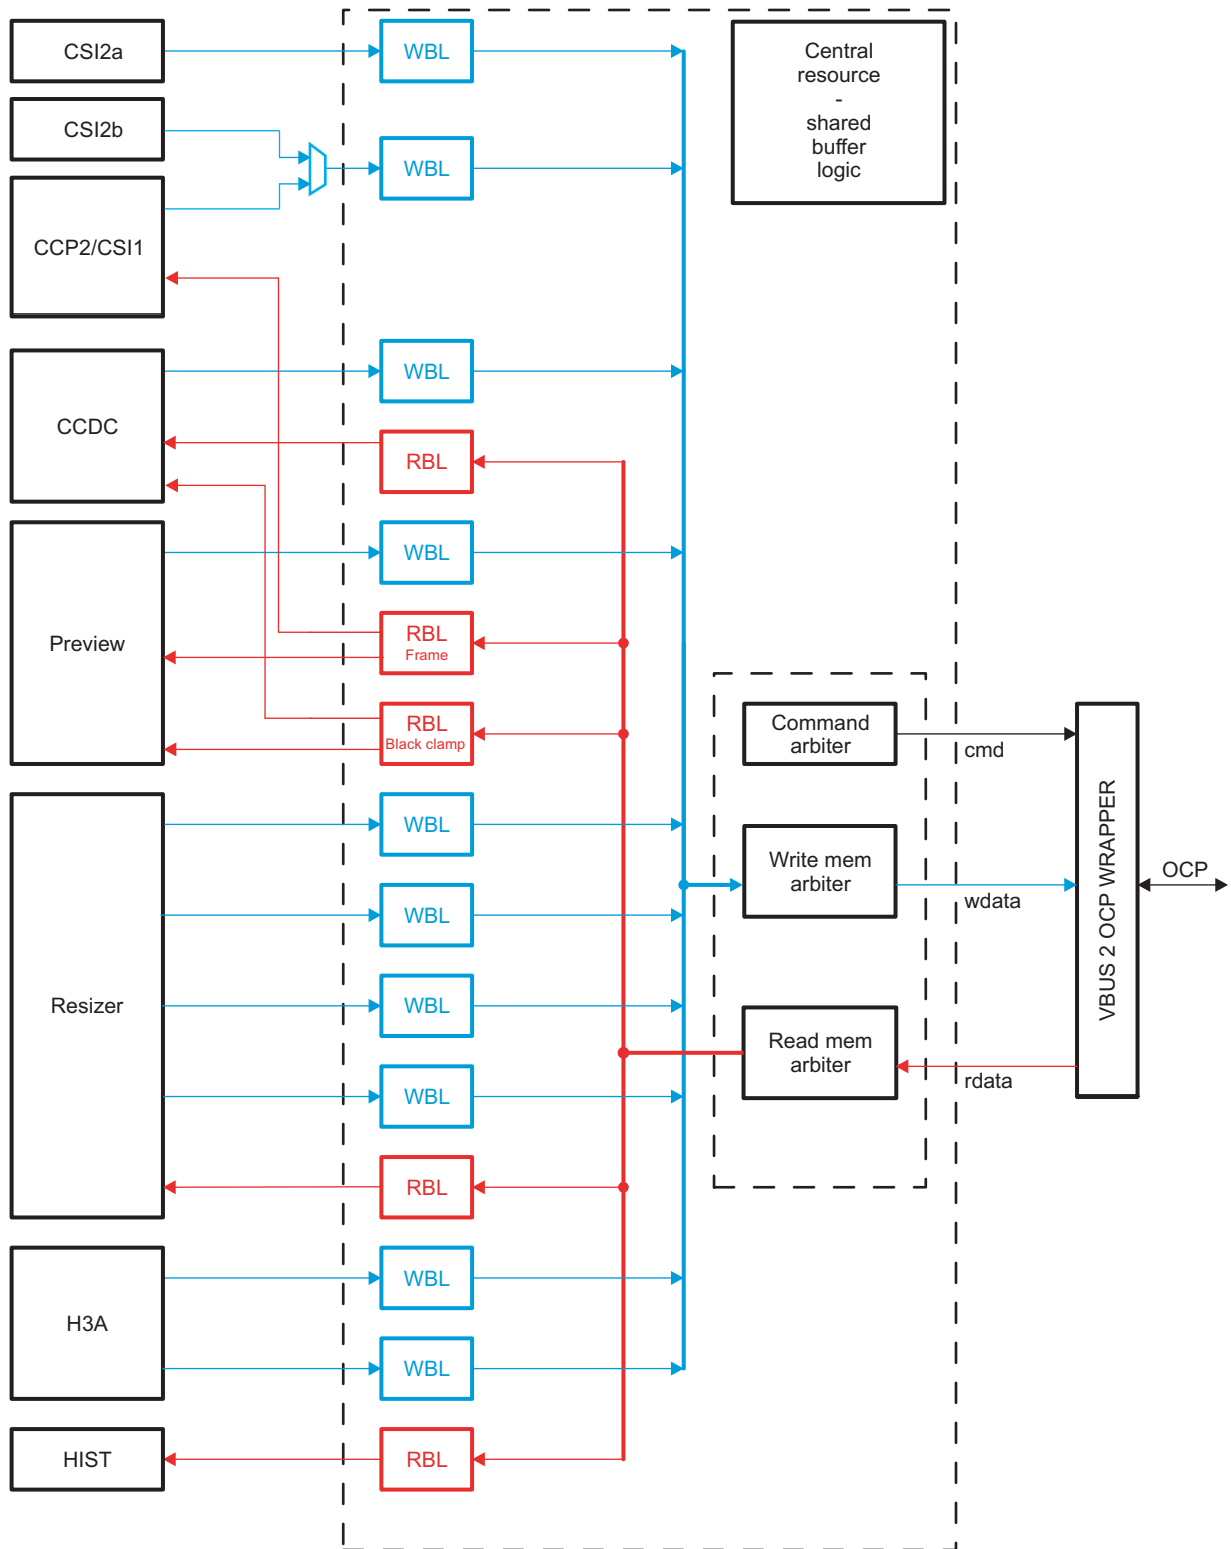

The central-resource SBL performs the following functions:

- Interface to the CCDC module:
 - Collects output data from the CCDC in the write buffer (1 port)
 - Transfers faulty-pixel table data to the CCDC from the read buffer (2 ports)
 - Transfer lens-shading compensation to the CCDC engine from the read buffer. This port is shared with PREVIEW module dark frame subtract port.
- Interface to the CSI2A, CSI2C, and CSI1/CCP2B receivers:
 - Collects output from CSI2A in the write buffer (1 port)
 - Collects output from CSI1/CCP2B and CSI2C in the write buffer (1 port)
 - Transfer input data to the CSI1/CCP2B from the read buffer. This port is shared with the PREVIEW module input data read port.
- Interface to the preview module:
 - Collects output data from the preview engine in the write buffer (1 port)
 - Transfer input data to the PREVIEW engine from the read buffer (1 ports). This port is shared with CSI1/CCP2B data read port.
 - Transfer dark frame subtract data to the PREVIEW engine from the read buffer . This port is shared with CCDC lens-shading compensation read port.
- Interface to the H3A module:
 - Collects output data from the H3A in the write buffer (2 ports)
- Interface to the histogram module:
 - Transfers input data to the histogram from the read buffer (1 port)
- Interface to the resizer module:
 - Collects output data from the resizer in the write buffer (4 ports)
 - Transfers input data to the resizer from the read buffer (1 port)
- Requests arbitration between the different initiators. Based on fixed priorities.
- Performs throttle memory read requests for preview, resizer, and histogram to limit bandwidth in memory-to-memory operations

6.4.9.1 Camera ISP Shared Buffer Logic Block Diagram

[Figure 6-98](#) shows the central-resource SBL. It comprises WBL and RBL blocks, read and write buffers, and arbitration logic. The VBUSM data-width to the memory is 64 bits.

Figure 6-98. Camera ISP Shared Buffer Logic Block Diagram

NOTE: Red = Reads; Blue = Writes

camisp-078

CAUTION

Because some of the read ports are shared, software must enable the modules that will use the shared read port. For more information, see [Section 6.4.9.2.3, Camera ISP Shared Buffer Logic Read Buffer Logic \(RBL\) and Read Buffer](#).

6.4.9.2 Camera ISP Shared Buffer Logic Functional Operations**6.4.9.2.1 Camera ISP Shared Buffer Logic Parameters**

[Table 6-47](#) summarizes the central-resource SBL parameters. Those parameters are fixed at design time and cannot be changed by users. The functional operations of the central-resource SBL are based on a fixed data size of 256 bytes called a data unit (DU). P0 has the highest priority and P14 has the lowest priority.

Table 6-47. Camera ISP Shared Buffer Logic Fixed Parameters

Port	Port Direction	Port Priority	Buffer Size Bytes	Description
CSI2A	WRITE	P3	1024 = 4DUs	CSI2A output port
CSI1/CCP2B and CSI2C	WRITE	P2	1024 = 4DUs	CSI1/CCP2B output port or CSI2C output port
CCDC	WRITE	P4	1024 = 4DUs	CCDC output port
	READ	P1	512 = 2DUs	CCDC fault pixel correction input port
PREVIEW	WRITE	P9	1024 = 4DUs	PREVIEW output port
	READ	P13	1024 = 4DUs	PREVIEW input port CSI1/CCP2B data input port
	READ	P0	1024 = 4DUs	PREVIEW dark-frame input port CCDC lens-shading compensation input port
RESIZER	WRITE	P5	1024 = 4DUs	RESIZER output line 1 port
	WRITE	P6	1024 = 4DUs	RESIZER output line 2 port
	WRITE	P7	1024 = 4DUs	RESIZER output line 3 port
	WRITE	P8	1024 = 4DUs	RESIZER output line 4 port
	READ	P12	1024 = 4DUs	RESIZER input port
H3A	WRITE	P10	512 = 2DUs	H3A output - AF port
	WRITE	P11	512 = 2DUs	H3A output - AE/AWB port
HIST	READ	P14	512 = 2DUs	HIST input port

6.4.9.2.2 Camera ISP Shared Buffer Logic Write-Buffer Logic (WBL) and Write Buffer

The central-resource SBL uses multiple WBL blocks to interface between the modules' write ports and the write-buffer memory.

- One WBL is instantiated for each module write port.
- Each WBL collects the module's write port output data and transfers the data to the write-buffer memory. Arbitration occurs between the WBL blocks to access the write-buffer memory.
- Each WBL is responsible for tracking all corresponding DUs in the write-buffer memory. There can be 2 or 4 DUs in the write buffer associated with a WBL.
- A WBL generates a command to memory when:
 - The write data crosses a DU boundary. At this point, the module starts filling a new DU. Also, the WBL generates a command to transfer the previous DU to memory.
 - An end-of-frame occurs. The DU (even if not full) is transferred to memory, and a command is

issued.

- An end-of-line occurs. The DU (even if not full) is transferred to the memory, and a command is issued.

6.4.9.2.3 Camera ISP Shared Buffer Logic Read Buffer Logic (RBL) and Read Buffer

The central resource SBL uses multiple RBL blocks to interface between the modules' read ports and the read-buffer memory.

- One RBL is instantiated for each module read port.
- Each RBL is responsible for accepting input data from the read-buffer memory and for sending the input data to the read port of the corresponding module.
- Each RBL is responsible for tracking all corresponding DUs in the read-buffer memory. There can be 2 or 4 DUs in the read buffer associated with a RBL.
- Unlike the WBL, the RBL is not responsible for issuing the commands to memory; each individual module is responsible for doing this.

Two read ports are shared:

- Between the PREVIEW module dark frame and the CCDC lens-shading compensation input
- Between the PREVIEW module and the CSI1/CCP2B module data read input

They can only be used by one module at a given time because there is no arbitration mechanism. Software must enable only one of the two possible features attached to a port and to select the correct multiplexer configuration using the [ISP_CTRL](#) [27] `SBL_SHARED_RPORTA` and [ISP_CTRL](#) [28] `SBL_SHARED_RPORTB` registers.

6.4.9.2.4 Camera ISP Shared Buffer Logic Arbitration

The central-resource SBL arbitrates between module requests, based on fixed priorities. Read and write requests are arbitrated independently.

A total of 8 commands can be active at a time. When a new slot opens, the highest-priority transfer enters the command queue.

RBLs/WBLs are ensured access to the read/write buffer memories at least once every other cycle.

NOTE: The hardware uses burst. All bursts are precise; the total number of transfers in the burst is known at the start of the burst. All writes are posted.

6.4.9.3 Camera ISP Shared Buffer Logic Memories

The central-resource shared-buffer module has three memories:

- READ BUFFER: Shared by all modules 256 x 128 bits.
- WRITE BUFFER 0: Used only by the resizer module 256 x 128 bits.
- WRITE BUFFER 1: Shared by all modules except RESIZER 256 x 128 bits.

6.4.9.4 Camera ISP Shared Buffer Logic Debug Registers

Some registers are available for debugging data transfers between a module and external memory. The read-only debug registers are divided into two categories:

- 8 global request registers to capture information about any of the 52 module request registers at a given time. Each register provides information about one DU. The number 16 corresponds to the maximum number of outstanding requests, according to the protocol. Each global request register provides the following information:
 - Individual module register command number. For modules with 2 individual requesters, this field displays either 0 or 1. For modules with 4 individual requesters, this field displays 0, 1, 2, or 3.
 - Source or destination module

- Data-flow direction
- Valid bit
- 52 individual module request registers (read or write information). Each register provides information about one DU. The number of request registers assigned (2 or 4) depends on memory bandwidth requirements; modules with lower requirements are assigned 2 request registers, while modules with higher bandwidths are assigned 4 request registers.

Table 6-48. Camera ISP Shared Buffer Logic Number of Request Registers

Port	RD/WR	Nb Request Registers	Description
CSI2A	WRITE	4 WR request registers	CSI2A output
CSI1/CCP2B and CSI2C	WRITE	4 WR request registers	CSI1/CCP2B or CSI2C output
CCDC	WRITE	4 WR request registers	CCDC output
	READ	2 RD request registers	CCDC fault pixel correction input
PREVIEW	WRITE	4 WR request registers	PREVIEW output
	READ	4 RD request registers	PREVIEW input
	READ	4 RD request registers	PREVIEW dark-frame input
RESIZER	WRITE	4 WR request registers	RESIZER output line 1
	WRITE	4 WR request registers	RESIZER output line 2
	WRITE	4 WR request registers	RESIZER output line 3
	WRITE	4 WR request registers	RESIZER output line 4
	READ	4 RD request registers	RESIZER input port
H3A	WRITE	2 WR request registers	H3A output - AF port
	WRITE	2 WR request registers	H3A output - AE/AWB port
HIST	READ	2 RD request registers	HIST input

Each write-request register provides the following information:

- Current byte count: Number of bytes in the block of data for this command, up to 256 bytes
- Data ready: Block of data confirmed by the module
- Data sent: Data sent to the destination and waiting for status
- Upper 20 bits of the address

Each read-request register provides the following information:

- Valid: Read requested from the module
- Waiting for data: Command accepted from the source
- Data available: Data received from the source and can be read by the module
- Byte count requested: Up to 256 bytes
- Upper 20 bits of the address

6.4.10 Camera ISP Circular Buffer

The circular buffer (CBUFF) maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

NOTE: Addresses can be further translated by the MMU.

6.4.10.1 Camera ISP Circular Buffer Feature List

The features are listed below:

- Two independent circular buffers (CBUFF0 and CBUFF1)
- Linear address space (virtual) mapped into a circular space (physical)
- Fully transparent for accesses out of the configured virtual space

- Maximum physical buffer size of 16x16M bytes:
 - Physical space is composed by 2,4,8 or 16 windows
 - Maximum allowed window size is 16M bytes
- Support for multiline write patterns
 - Used together with the resizer in upscale mode. Each buffer must contain at least ceil (vertical zoom factor) images lines
- Support of 2D addressing modes
- Memory fragmentation support for CBUFF0
- VRFB context grouping support
- Strong error detection mechanisms
- Buffer addresses are 64-bit aligned, but window fill level managing is byte accurate.
- Read and write accesses are supported.
- Bandwidth Control Feedback loop connected to the CSI1/CCP2B receiver flexible input

6.4.10.2 Camera ISP Circular Buffer Interrupts

All events generated (see [Table 6-16](#) for details) by the circular buffer are merged into a single event at camera ISP level. This event can be mapped to MPU SS by enabling the [ISP_IRQ0ENABLE \[21\]](#) CBUFF_IRQ bit or to IVA2.2 by enabling the [ISP_IRQ1ENABLE \[21\]](#) CBUFF_IRQ bit.

6.4.10.3 Camera ISP Circular Buffer Functional Description

The CBUFF module maps a virtual address space to a physical space called circular buffer. The CBUFF module can handle up to 2 independent circular buffers CBUFF0 and CBUFF1.

This section gives an overview of typical uses of the module.

6.4.10.3.1 Camera ISP Circular Buffer Bandwidth Control Feedback Loop

The bandwidth control feedback (BCF) feature can be used in memory to memory operation when the camera ISP reads data through the CSIb receivers flexible input.

At a given time a certain number of physical buffers are available for the processor. Depending, if the circular buffer is configured in read or write mode, the processor can, respectively, write or read those physical buffers.

When the number of physical buffers to be processed by the processor increases, the number of physical buffers available to the camera ISP decreases. When the number of physical buffers available for the camera ISP becomes too low, the corresponding BCF signal is asserted. This signal can be used to stall the data read flow.

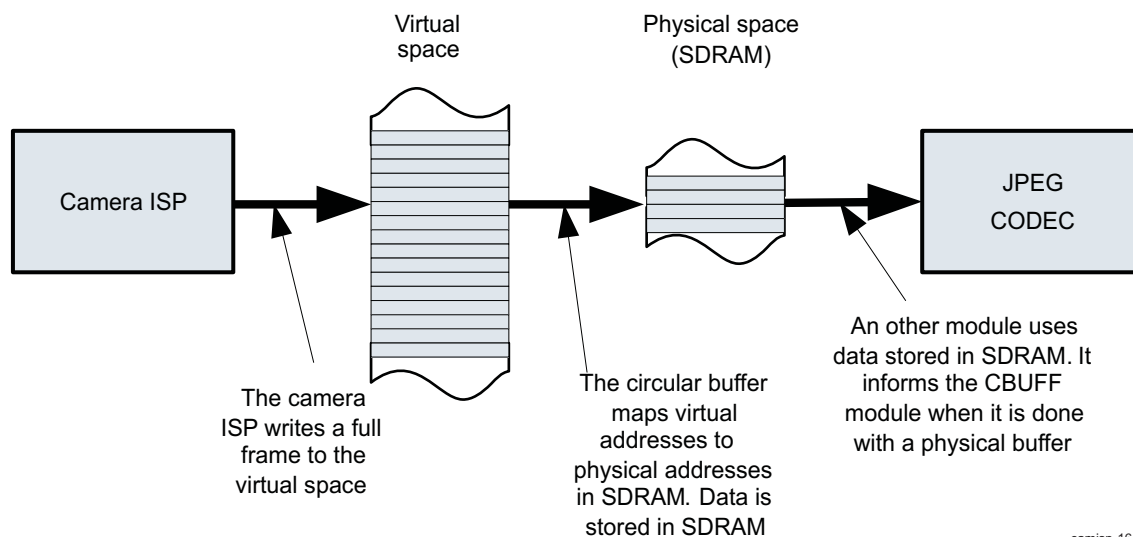

The camera ISP supports two mechanisms to reduce the processing speed in memory to memory operation:

- Add a fixed delay between memory read requests. Delays can be added:
 - At SBL level for all image data read ports (histogram, preview, CSI1/CCP2B and resizer)
 - At CSI1/CCP2B module level by slowing down the video port clock
- Stall memory reads based on the level of the circular buffer. That is the purpose of the BCF feature described in this section.

6.4.10.3.1.1 Camera ISP Circular Buffer Single Slice Mode

The camera ISP writes data with an incremental addressing scheme to the virtual space. The physical buffer is smaller than the virtual space. Therefore, the physical buffer locations is read or written multiple times. See [Figure 6-99](#).

Figure 6-99. Camera ISP Circular Buffer Single Slice Buffer (Write Mode)

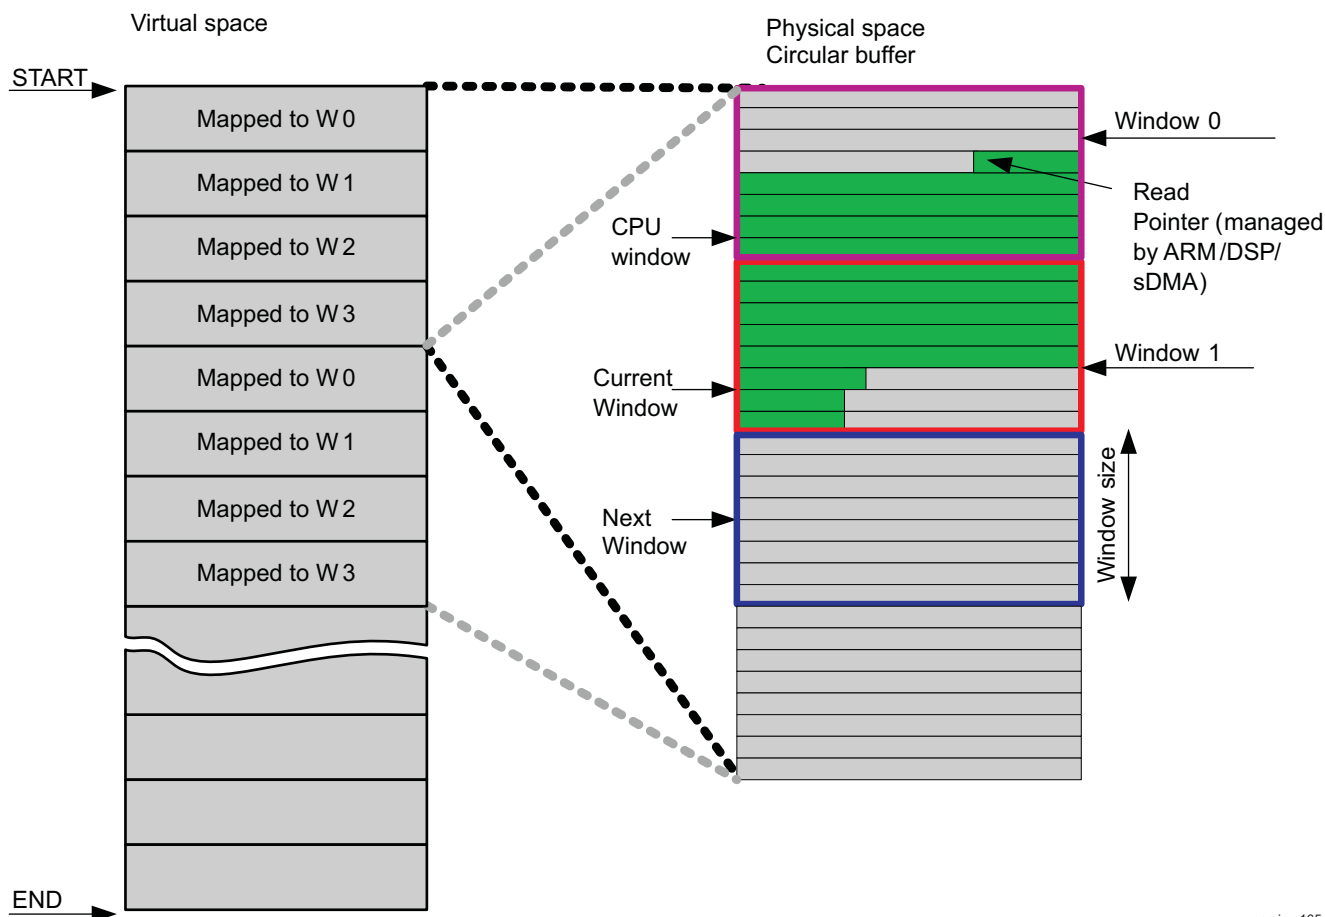

camisp-164

Physically, this circular buffer is typically in the SDRAM. The virtual space is defined by a start and an end address. The physical buffer is defined by a start address, a window size, and a window count. It is contiguous in memory.

Figure 6-100 shows the buffer organization for a 4-window buffer.

Figure 6-100. Camera ISP Circular Buffer Single Slice Buffer Example (Write Mode)

camisp-165

The CBUFF module can manage two independent circular buffers in single slice mode.

In case of memory-to-memory operation, the module using the data (that is, JPEG CODEC) written by the ISP into the circular buffer may be slower than the camera ISP. That is especially the case when the resizer is used for upscaling.

In this section, it is assumed that the data to be read by the camera ISP is a full frame completely present in physical memory. Sliced buffer capability is only used the buffer data at the output of the camera ISP. Therefore, the circular buffer is configured in write mode.

The basic idea is to stall the read data flow at CS1b flexible input level. This is done by blocking the response phase of the CS1b interconnect read master port. Blocking the response phase rather than the request phase allows data prefetch at SBL level.

When the count of full windows is greater than or equal to the value defined in the [CBUFFx_CTRL\[7:4\]](#) BCF register, the data flow between the SBL buffer and the CSI1/CCP2B data read port is stalled. Data transfers resume when the full window count falls below the defined limit.

Stalling the data flow at this level does not prevent the SBL from fetching data until its buffers are full. Therefore, when data transfer resumes, data are available quickly at the CSI1/CCP2B read port level, and ISP processing can resume.

Due to SBL buffering, some data may be sent out to the circular buffer when the stall command is activated. Firmware must allocate enough space in the circular buffer to avoid an overflow. The amount of buffered data depends on the ISP configuration:

- The camera ISP Video processing hardware can contain up to 10 pixels that are sent to the SBL after stall control is activated.
- The SBL can store up to four DUs at the output of the PREVIEW module. Therefore, when the circular buffer is filled from the PREVIEW module there must be enough space to store the extra 1K byte of data.
- The data path between the resizer and preview module goes through the SBL and data is internally buffered. The SBL can buffer up to 4 DUs between the PREVIEW and RESIZER module. In other words, when the input of the PREVIEW module is stalled, the RESIZER receives up to 2K bytes before it stalls.
- The SBL can store up to four DUs for each of the RESIZERS write ports. The count of ports used by the resizer depends on the vertical scaling factor; it uses $\text{ceil}(\text{vscale})$ ports. Each port writes into one image line and can buffer up to 1K byte.
- Depending on the resizing factor, the next write window may already contain up to three full video lines.

The largest amount of buffering is required when all of the following occur:

- The PREVIEW module is used.
- The RESIZER is used with a rescaling factor of 4x in the horizontal and vertical direction.
- The window size is not a multiple of the vertical up scaling factor.

Example 6-1. Camera ISP Circular Buffer Example of 4x Digital Zoom Use:

This example shows how to calculate the minimum required window count when this feature is used.

It is assumed that the camera ISP reads a VGA RAW8 image from memory, processes it in the preview, and scales it up to 5M pix (2560x1920). The circular buffer is used for temporary storage between the JPEG CODEC and the camera ISP. Each window is configured to contain 8 video lines and the stall command is issued when at least two windows of the circular buffer are full.

Because the circular buffer window size is a multiple of the vertical upscaling factor, the next write window is empty when the stall command is issued. However, up to 1K byte = 512 pixels are stored for each write port of the resizer. This data is written as a 512x4 pixel bloc to the circular buffer by the SBL. Between the PREVIEW and RESIZER up to 1kbyte = 512 pixels are stored. This data expands to a block of 512x4x4 pixels written to the circular buffer by the SBL. In other words, up to 7 lines of the circular buffer may be filled after the stall command is issued. A minimum of four windows must be allocated to avoid an overflow of the circular buffer.

Example 6-1. Camera ISP Circular Buffer Example of 4x Digital Zoom Use: (continued)**Figure 6-101. Camera ISP Circular Buffer Control Feedback Loop Example**

camisp-163

The CODEC reads data from the circular buffer and flag windows as done. In this example, the stall command is released when the CODEC has completed processing W0 and W1. The camera ISP resumes writing into W3.

NOTE: Software can control the minimum full window count to issue the stall command using the `CBUFFx_CTRL[7:4]` BCF register. Setting this value to 1 or 2 in this example may negatively affect the performance, because only up to two or three windows can be used.

6.4.10.3.1.2 Camera ISP Circular Buffer Extended Slice Mode

In extended slice mode, both circular buffers managed by the CBUFF module are used together. One provides address translation for the read data flow, and the other for a write data flow.

Figure 6-102. Camera ISP Circular Buffer Extended Slice Buffer Example

The camera ISP prefetches data and buffers it in the SBL. The CSI1/CCP2B flexible input pre-buffers up to 1K byte of data. In other words, the stall control for the CSI1/CCP2B interconnect read master port must be triggered in advance. Otherwise, the camera ISP may prefetch invalid data.

The last moment when the CSI1/CCP2B interconnect read master port can be safely stalled is when the physical read buffer still contains 1K byte of valid data. The camera ISP may or may not then read the remaining data into its internal SBL buffer.

The minimum amount of buffered data depends on the circular buffer configuration and the used data format.

When the processor filling the read buffer has no more data to write, the BCF feature must be disabled (clear `ISP_CTRL [23:22] CBUFF0_BCF_CTRL` or `ISP_CTRL[25:24] CBUFF1_BCF_CTRL`) for the CBUFF attached to the read data flow. This allows the camera ISP to prefetch the remaining data from the buffer without stalling.

6.4.10.3.1.3 Camera ISP Circular Buffer Fragmentation Support

This mode is available only for context 0 and CBUFF0. The mapped physical space does not need to be contiguous in memory.

NOTE: Software must ensure proper configuration of the CBUFF0 specific fragmentation support feature. Thus, the `CBUFFx_ADDRy` register must be configured correctly even if functionality was not initially required when data was accepted from ISP.

Software defines the location of each physical window using `CBUFF0_ADDR0` through `CBUFF0_ADDR15` (see `CBUFFx_ADDRy`). Figure 6-103 shows the fragmentation support.

Figure 6-103. Camera ISP Circular Buffer Fragmentation Support

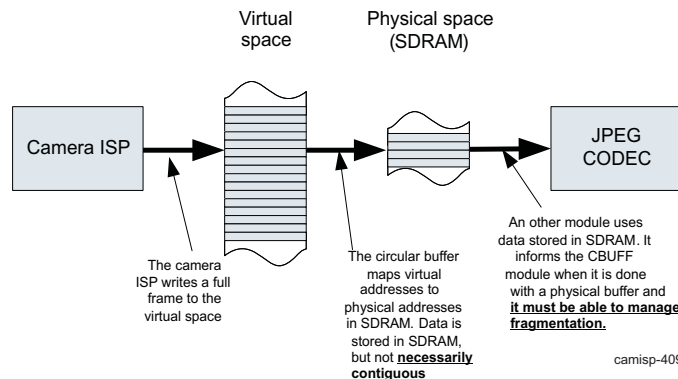

Table 6-49 provides the physical address of physical windows 0 to 15 for fragmentation functionality.

Table 6-49. Camera ISP Circular Buffer Fragmentation Support Physical Window Addresses

Physical Window	Fragmentation ON Register
0	CBUFF0_ADDR0
1	CBUFF0_ADDR1
2	CBUFF0_ADDR2
3	CBUFF0_ADDR3
4	CBUFF0_ADDR4
5	CBUFF0_ADDR5
6	CBUFF0_ADDR6
7	CBUFF0_ADDR7
8	CBUFF0_ADDR8
9	CBUFF0_ADDR9
10	CBUFF0_ADDR10
11	CBUFF0_ADDR11
12	CBUFF0_ADDR12
13	CBUFF0_ADDR13
14	CBUFF0_ADDR14
15	CBUFF0_ADDR15

6.4.10.3.1.4 Camera ISP Circular Buffer VRFB Context Grouping

The VRFB is part of the SMS module and provides support for image rotation by writing the data into SDRAM and reading it back. The VRFB can rotate frames of up to 2k * 2k pixels per context. That is sufficient to rotate the following image sizes

Table 6-50. Camera ISP Circular Buffer VRFB Maximum Supported Frame Size

Frame size	Aspect ratio
3.1 Mega Pixel	4/3
2.8 Mega Pixel	3/2
2.3 Mega Pixel	16/9

The CBUFF module can optionally perform address translation to group 4 contexts together. This extends the maximum frame size than can be rotated to the following:

Table 6-51. Camera ISP Circular Buffer VRFB Extended Supported Frame Size

Frame size	Aspect ratio
12.5 Mega Pixel	4/3
11.1 Mega Pixel	3/2
9.4 Mega Pixel	16/9

NOTE: VRFB context grouping is a standalone feature. It cannot be combined with circular buffering or fragmentation.

The VRFB supports a total of 12 contexts. The CBUFF VRFB context grouping feature groups 4 contexts together to provide a larger virtual frame buffer. CBUFF can handle up to 3 groups or 4 VRFB contexts each.

The software chooses which VRFB contexts to use by defining the base address of the 1st of the 4 contexts using the `CBUFF_VRFB_CTRL.BASEx` register (x = 0, 1, or 2). Software must ensure that translated regions do not overlap.

Software also needs to define the data width (8, 16, or 32-bits) and the orientation (0, 90, 180, or 270 degrees) using the `CBUFF_VRFB_CTRL.WIDTHx` and `CBUFF_VRFB_CTRL.ORIENTATIONx` registers.

Translation is enabled by setting the `CBUFF_VRFB_CTRL.ENABLEx` bit. Software shall not change the translation configuration or enable/disable the translation while there is active traffic from ISP interface input port in the translated region (`CBUFF_VRFB_CTRL.BASEx*256M` bytes to `CBUFF_VRFB_CTRL.BASEx+1)*256M` bytes).

Figure 6-104 shows how the "large" virtual frame buffer seen in the address map of ISP interface input port is mapped to 4 "small" virtual frames accesses through interface output port.

Figure 6-104. Camera ISP Circular VRFB Buffer Performed Translation

6.4.10.3.2 Camera ISP Circular Buffer Window Management

This section explains the internal address remapping and windows management algorithm. Internally the module maintains some variables in addition to the configuration registers.

The module manages two circular buffers in parallel. Those are called CBUFF0 and CBUFF1.

Table 6-52. Camera ISP Circular Buffer Internal Variables

Quantity	Description
CWx	Current window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[11:8]</code> CW register.
NWx	Next window index for buffer x (x = 0, 1). Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[19:16]</code> NW register.
CPUWx	Window in the physical buffer that can be accessed by the CPU. Possible values are 0 to allowed window count. The current value can be read using the <code>CBUFFx_STATUS[3:0]</code> CPUW register.
FCOx	Start address, in the virtual space, of the current window. This is an internal quantity that cannot be accessed by software.
OFFSETy	This is an internal quantity that cannot be accessed by software. y = 0: Address offset used when the current window of buffer 0 is accessed y = 1: Address offset used when the next window of buffer 0 is accessed y = 2: Address offset used when the current window of buffer 1 is accessed y = 3: Address offset used when the next window of buffer 1 is accessed
LEVELy	This is an internal quantity that cannot be accessed by software. y = 0: Amount of data, in bytes, read or written in the current window of buffer 0 y = 1: Amount of data, in bytes, read or written in the next window of buffer 0 y = 2: Amount of data, in bytes, read or written in the current window of buffer 1 y = 3: Amount of data, in bytes, read or written in the next window of buffer 1

6.4.10.3.2.1 Camera ISP Circular Buffer Startup

The status of a circular buffer (CBUFF0 or CBUFF1) is reset when it is disabled. This does not affect the configuration registers or the `CBUFF_IRQSTATUS` register. Table 6-53 shows the internal state after reset.

Table 6-53. Camera ISP Circular Buffer Internal State After Reset

Quantity	Description
CWx	0
NWx	1
CPUWx	0
FCOx	CBUFFx_START
OFFSET0	0
OFSFET1	0
OFFSET2,3	0
LEVELy	0

6.4.10.3.2.2 Camera ISP Circular Buffer Access Identification

For each access to the virtual space, the CBUFF module first checks the address (ADDR) to classify the transaction into one of the categories listed in [Table 6-54](#).

Table 6-54. Camera ISP Circular Buffer Address Identification

ID	Label	Condition
0	CW_CBUFF0	CBUFFx_CTRL [0] ENABLE = 1 and ADDR=FCO0 and ADDRFCO0 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
1	NW_CBUFF0	CBUFFx_CTRL [0] ENABLE=1 (x = 0) and ADDR=FCO0 + CBUFFx_WINDOWSIZE and ADDRFCO0 + 2* CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 0)
2	CW_CBUFF1	CBUFFx_CTRL [0] ENABLE=1 and ADDR=FCO1 and ADDRFCO1 + CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
3	NW_CBUFF1	CBUFFx_CTRL [0] ENABLE=1 and ADDR=FCO1 + CBUFFx_WINDOWSIZE and ADDRFCO1 + 2* CBUFFx_WINDOWSIZE and ADDR= CBUFFx_END (x = 1)
4	ERR_CBUFF0	CBUFFx_CTRL [0] ENABLE=1 and ADDR= CBUFFx_START and ADDR= CBUFFx_END (x = 0)
5	ERR_CBUFF1	CBUFFx_CTRL [0] ENABLE=1 and ADDR= CBUFFx_START and ADDR= CBUFFx_END (x = 1)
6	TRANSPARENT	Always true

Lower IDs correspond to higher priorities in case multiple conditions are true. For example, when the current virtual window of the circular buffer 0 is accessed, at least the tests for categories CW_CBUFF0 and ERR_CBUFF0 are true. The final category is CW_CBUFF0, because it has a higher priority.

Further processing depends on the category:

- TRANSPARENT: Accesses flow through the module without changing its internal state or any translation.
- ERR_CBUFF0 and ERR_CBUFF1: The module goes into error state for the concerned buffer (CBUFF0 or CBUFF1) and set the [CBUFF_IRQSTATUS](#)[1] IRQ_CBUFF0_INVALID bit (or [CBUFF_IRQSTATUS](#)[4] IRQ_CBUFF1_INVALID). When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between [CBUFFx_START](#) and [CBUFFx_END](#) (x = 0) is not transmitted to the interconnect. There are two ways to leave the error state:
 - Hardware reset
 - Disable and re-enable the buffer (CBUFF0 or CBUFF1) in error state

Accesses outside of the virtual space from the circular buffer in error state are not affected.

- CW_CBUFF0, NW_CBUFF0, CW_CBUFF1 and NW_CBUFF1: The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read or write). Otherwise, an IRQ_CBUFFx_INVALID event is set and CBUFFx goes into the error state.

6.4.10.3.2.3 Camera ISP Circular Buffer Address Translation

An offset is selected depending on the access category (see [Section 6.4.10.3.2.1](#), *Camera ISP Circular Buffer Startup*) and the internal state of the accessed buffer. [Table 6-55](#) lists possible cases.

Table 6-55. Camera ISP Circular Buffer Address Translation

Condition	Address Translation
CBUFFx_CTRL[0] ENABLE=1 and ADDR= CBUFFx_START and ADDR= CBUFFx_END and CBUFF0 in error state (x = 0)	Access cancelled
CBUFFx_CTRL[0] ENABLE=1 and ADDR= CBUFFx_START and ADDR= CBUFFx_END and CBUFF1 in error state (x = 1)	Access cancelled
Category = CW_CBUFF0	ADDROUT = ADDRIN-OFFSET0
Category = NW_CBUFF0	ADDROUT = ADDRIN-OFFSET1
Category = CW_CBUFF1	ADDROUT = ADDRIN-OFFSET2
Category = NW_CBUFF1	ADDROUT = ADDRIN-OFFSET3
Category = ERR_CBUFF0	Access cancelled
Category = ERR_CBUFF1	Access cancelled
Category = TRANSPARENT	ADDROUT = ADDRIN

6.4.10.3.2.4 Camera ISP Circular Buffer Window Fill Level

Each time an access is performed into an active window (CW_CBUFF0, NW_CBUFF0, CW_CBUFF1 or NW_CBUFF1) the window level is updated. The corresponding LEVELy is incremented according to the BYTEEN input of the interconnect port. All possible BYTEEN patterns are supported. [Table 6-56](#) shows some examples. The basic idea is to count the number of ones in the BYTEEN input.

Table 6-56. Camera ISP Circular Buffer Window Level Increment

BYTEEN	LEVELy Increment	Comment
0x00	+0	No access
0x01	+1	8 bit access
0x02	+1	8 bit access
0x03	+2	16 bit access
...
0x07	+3	24 bit access
...
0x0F	+4	32 bit access
...
0xF0	+4	32 bit access
...
0xFF	+8	64 bit access

The window level is compared to [CBUFFx_THRESHOLD](#). As listed in [Table 6-57](#), the following situations may occur:

Table 6-57. Camera ISP Circular Buffer Window Level Comparison

Condition	Description
LEVEL0= CBUFFx_THRESHOLD (x = 0)	Current window of buffer 0 full. Internal window indexes, levels, and offsets are updated.
LEVEL1= CBUFFx_THRESHOLD (x = 0)	Next window of buffer 0 full. An IRQ_CBUFF0_INVALID error event is set and CBUFF0 enters the error state.
LEVEL2= CBUFFx_THRESHOLD (x = 1)	Current window of buffer 1 full
LEVEL3= CBUFFx_THRESHOLD (x = 1)	Next window of buffer 1 full. An IRQ_CBUFF1_INVALID error event is set and CBUFF1 enters the error state.

6.4.10.3.2.5 Camera ISP Circular Buffer Window Pointer and Offset Update

When the current window of a circular buffer ([CBUFFx](#), x = 0 or 1) is full:

- The "next window" becomes the "current window"
 - $CW_x - NW$
 - $LEVEL(2*x) - LEVEL(2*x+1)$
 - $OFFSET(2*x) - OFFSET(2*x+1)$
 - $FCO_x - FCO_x + CBUFFx_WINDOWSIZE$
- A new "next window" if opened. The update is done in a circular manner: the first window in the physical space is reused after the last one
 - $NW - (NW+1) \text{ modulo } WC$
 - $LEVEL(2*x+1) - 0$
 - $VPA - VPA + CBUFFx_WINDOWSIZE$
 - When fragmentation used for [CBUFF0](#):
 - $OFFSET(2*x+1) - OFFSET(2*x+1) + VPA * CBUFFx_WINDOWSIZE - CBUFF0_ADDR[CBUFF0_STATUS[WA]]$
 - When the "next window" is moved from the last buffer to the first:
 - $OFFSET(2*x+1) - OFFSET(2*x+1) + WC_x * CBUFFx_WINDOWSIZE$

NOTE: WC is the window count defined by the [CBUFFx_CTRL\[9:8\]](#) WCOUNT register.

6.4.10.3.3 Camera ISP Circular Buffer CPU Interaction

The [CBUFF](#) module sets an [IRQ_CBUFFx_READY](#) event to inform the CPU that it can access the [CPUx](#) window in the physical buffer. The [CBUFF](#) module cannot monitor CPU accesses to the physical buffer. The CPU must indicate when it has completed the processing of the [CPUWx](#) window by writing the [CBUFFx_CTRL\[2\]](#) DONE bit. This increments the CPU window index [CPUWx](#) by one modulo the window count.

The behavior depends on whether read or write mode has been selected using the [CBUFFx_CTRL\[1\]](#) RWMODE bit.

NOTE: Some details of this feature are not available in the public domain.

6.4.11 Camera ISP MMU Logic

6.4.11.1 Camera ISP MMU Features

The camera ISP MMU contains a translation lookaside buffer (TLB) that holds translations and properties for current pages. This TLB can be managed statically through the configuration slave port, or by the internal hardware table-walking logic (TWL), which can autonomously traverse the page table on a TLB miss. The TWL can be enabled or disabled (MMU.MMU_CNTL [2] TWLENABLE).

On a TLB miss, the initiator is stalled until a valid address translation is found. If no valid translation is found, a translation fault interrupt is generated to the processor. It is a nonrecoverable situation, which leads to the camera ISP being reset by the processor software.

The MMU provides up to 4G bytes of virtual memory.

6.4.11.2 Camera ISP MMU Functional Description

For a detailed description of the MMU, see [Chapter 15, Memory Management Units](#).

NOTE: In the camera ISP MMU, the endianness feature is available for write, but conversion for read is not possible.

6.5 Camera ISP Basic Programming Model

6.5.1 Programming the ISP PRCM Clocks Configuration

The camera subsystem clocks are provided by the PRCM module. The software must set the PRCM registers as follows:

1. To set the cam_mclk:

The DPPLL4_ALWON_FCLKOUT clock is sourced by the system clock (SYS_CLK) at a X frequency and calculated as follows:

$$DPPLL4_ALWON_FLCKOUT = [SYS_CLK (X \text{ frequency}) \times 2 \times M (0xE1)] / [N (0x9) + 1]$$

$$cam_mclk = DPPLL4_ALWON_FCLKOUT / CLKSEL_CAM (4)$$

$$PRCM.CM_CLKSEL_CAM.CLKSEL_CAM = x$$

2. Enable the cam_fclk clock:

$$PRCM.CM_FLCKEN_CAM [0] EN_CAM = 0x1$$

3. Enable the cam_iclk clock:

$$PRCM.CM_ICLKEN_CAM [0] EN_CAM = 0x1$$

[Table 6-58](#) lists the registers to configure the camera subsystem clock configuration step.

Table 6-58. Camera ISP PRCM Registers Settings

Register Name	Address	Value Description
PRCM.CM_CLKSEL_CAM	0x4800 4F40	DPPLL4 divisor set to 0x4
PRCM.CM_FLCKEN_CAM	0x4800 4F00	Enable CAM_FCLK
PRCM.CM_ICLKEN_CAM	0x4800 4F10	Enable CAM_ICLK

6.5.2 Programming the CSI1/CCP2B or CSI2 Receiver Associated PHY

6.5.2.1 Camera ISP CSIPHY Initialization for Work With CSI2 Receiver

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2 receiver registers to receive signals/data from the CSIPHY:
 - (a) Configure all necessary CSI2 registers:
 - (i) Set [CSI2_COMPLEXIO_CFG1\[10:8\] DATA2_POSITION](#).

- (ii) Set `CSI2_COMPLEXIO_CFG1[6:4]` DATA1_POSITION.
- (iii) Set `CSI2_COMPLEXIO_CFG1[2:0]` CLOCK_POSITION.
- (iv) Set `CONTROL_CAMERA_PHY_CTRL[1:0]` R_CONTROL_CAMERA2_PHY_CAMMODE or `CONTROL_CAMERA_PHY_CTRL[3:2]` R_CONTROL_CAMERA1_PHY_CAMMODE.

CAUTION

This must be done before the CSIPHY is active.

2. CSIPHY and link initialization sequence:

- (a) Deassert the CSIPHY reset:
 - (i) Set `CSI2_COMPLEXIO_CFG1[30]` RESET_CTRL to 0x1.
- (b) The following registers can be set only after deasserting the CSIPHY reset, and before asserting the ForceRxMode signal:
 - `CSIPHY_REG0`
 - `CSIPHY_REG1`
 - `CSIPHY_REG2`
- (c) Assert the ForceRxMode signal:
 - (i) Set `CSI2_TIMING[15]` FORCE_RX_MODE_IO1 to 0x1.
- (d) Connect the pulldown on the link (DP/DN) by asserting the respective PIPD* signals (PIPD* = 0):
 - For CSIPHY1: Pull down on signals through padconf registers:
 - cam_d6:
 - `CONTROL_PADCONF_CAM_D5[24]` INPUTENABLE1 = 0x1
 - `CONTROL_PADCONF_CAM_D5[20]` PULLTYPESELECT1 = 0x0
 - `CONTROL_PADCONF_CAM_D5[19]` PULLUDENABLE1 = 0x1
 - cam_d7:
 - `CONTROL_PADCONF_CAM_D7[8]` INPUTENABLE0 = 0x1
 - `CONTROL_PADCONF_CAM_D7[4]` PULLTYPESELECT0 = 0x0
 - `CONTROL_PADCONF_CAM_D7[3]` PULLUDENABLE0 = 0x1
 - cam_d8:
 - `CONTROL_PADCONF_CAM_D7[24]` INPUTENABLE1 = 0x1
 - `CONTROL_PADCONF_CAM_D7[20]` PULLTYPESELECT1 = 0x0
 - `CONTROL_PADCONF_CAM_D7[19]` PULLUDENABLE1 = 0x1
 - cam_d9:
 - `CONTROL_PADCONF_CAM_D9[8]` INPUTENABLE0 = 0x1
 - `CONTROL_PADCONF_CAM_D9[4]` PULLTYPESELECT0 = 0x0
 - `CONTROL_PADCONF_CAM_D9[3]` PULLUDENABLE0 = 0x1
 - For CSIPHY2: Pull down on signals through padconf registers:
 - cam_d0:
 - `CONTROL_PADCONF_CAM_FLD[24]` INPUTENABLE1 = 0x1
 - `CONTROL_PADCONF_CAM_FLD[20]` PULLTYPESELECT1 = 0x0
 - `CONTROL_PADCONF_CAM_FLD[19]` PULLUDENABLE1 = 0x1
 - cam_d1:
 - `CONTROL_PADCONF_CAM_D1[8]` INPUTENABLE0 = 0x1
 - `CONTROL_PADCONF_CAM_D1[4]` PULLTYPESELECT0 = 0x0
 - `CONTROL_PADCONF_CAM_D1[3]` PULLUDENABLE0 = 0x1

- csi2_dx0:
 - CONTROL_PADCONF_CSI2_DX0[8] INPUTENABLE0 = 0x1
 - CONTROL_PADCONF_CSI2_DX0[4] PULLTYPESELECT0 = 0x0
 - CONTROL_PADCONF_CSI2_DX0[3] PULLUDENABLE0 = 0x1
- csi2_dy0:
 - CONTROL_PADCONF_CSI2_DX0[24] INPUTENABLE1 = 0x1
 - CONTROL_PADCONF_CSI2_DX0[20] PULLTYPESELECT1 = 0x0
 - CONTROL_PADCONF_CSI2_DX0[19] PULLUDENABLE1 = 0x1
- csi2_dx1:
 - CONTROL_PADCONF_CSI2_DX1[8] INPUTENABLE0 = 0x1
 - CONTROL_PADCONF_CSI2_DX1[4] PULLTYPESELECT0 = 0x0
 - CONTROL_PADCONF_CSI2_DX1[3] PULLUDENABLE0 = 0x1
- csi2_dy1:
 - CONTROL_PADCONF_CSI2_DX1[24] INPUTENABLE1 = 0x1
 - CONTROL_PADCONF_CSI2_DX1[20] PULLTYPESELECT1 = 0x0
 - CONTROL_PADCONF_CSI2_DX1[19] PULLUDENABLE1 = 0x1
- (e) Power up the CSIPHY:
 - (i) Set [CSI2_COMPLEXIO_CFG1\[28:27\]](#) PWR_CMD to 0x1.
- (f) Check that the state status reaches the ON state:
 - [CSI2_COMPLEXIO_CFG1\[26:25\]](#) PWR_STATUS = 0x1
- (g) Wait for STOPSTATE = 1 (for all enabled lane modules):
 - (i) The timer is set through the [CSI2_TIMING\[14:0\]](#) bit field. The reset value can be kept.
 - (ii) Wait until [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.
- (h) Release PIPD* (= 1):
 - For CSIPHY1: Pull up on signals through padconf registers:
 - cam_d6:
 - CONTROL_PADCONF_CAM_D5[20] PULLTYPESELECT1 = 0x1
 - cam_d7:
 - CONTROL_PADCONF_CAM_D7[4] PULLTYPESELECT0 = 0x1
 - cam_d8:
 - CONTROL_PADCONF_CAM_D7[20] PULLTYPESELECT1 = 0x1
 - cam_d9:
 - CONTROL_PADCONF_CAM_D9[4] PULLTYPESELECT0 = 0x1
 - For CSIPHY2: Pull up on signals through padconf registers:
 - cam_d0:
 - CONTROL_PADCONF_CAM_FLD[20] PULLTYPESELECT1 = 0x1
 - cam_d1:
 - CONTROL_PADCONF_CAM_D1[4] PULLTYPESELECT0 = 0x1
 - csi2_dx0:
 - CONTROL_PADCONF_CSI2_DX0[4] PULLTYPESELECT0 = 0x1
 - csi2_dy0:
 - CONTROL_PADCONF_CSI2_DX0[20] PULLTYPESELECT1 = 0x1
 - csi2_dx1:
 - CONTROL_PADCONF_CSI2_DX1[4] PULLTYPESELECT0 = 0x1
 - csi2_dy1:

- CONTROL_PADCONF_CSI2_DX1[20] PULLTYPESELECT1 = 0x1
- (i) The CSIPHY is initialized and ready/active in CSI2 mode.

6.5.2.2 Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI1/CCP2B receiver registers to receive signals/data from the CSIPHY:
 - (a) Configure all CSI1/CCP2B registers:
 - (i) Set `CSI2_COMPLEXIO_CFG1[10:8] DATA2_POSITION`.
CCP2 mode for work with CSIPHY1:
0x0: Not used/connected
CCP2 mode for work with CSIPHY2:
0x0: Not used/connected
 - (ii) Set `CSI2_COMPLEXIO_CFG1[6:4] DATA1_POSITION`.
CCP2 mode for work with CSIPHY1:
0x1: Data lane 1 is at position 2.
0x2: Data lane 1 is at position 1.
CCP2 mode for work with CSIPHY2:
0x1: Data lane 1 is at position 2.
0x2: Data lane 1 is at position 1.
 - (iii) Set `CSI2_COMPLEXIO_CFG1[2:0] CLOCK_POSITION`.
CCP2 mode for work with CSIPHY1:
0x1: Clock lane is at position 2.
0x5: Clock lane is at position 1.
CCP2 mode for work with CSIPHY2:
0x1: Clock lane is at position 2.
0x5: Clock lane is at position 1.
 - (iv) Set `CONTROL_CAMERA_PHY_CTRL[1:0] R_CONTROL_CAMERA2_PHY_CAMMODE` or `CONTROL_CAMERA_PHY_CTRL[3:2] R_CONTROL_CAMERA1_PHY_CAMMODE`.

CAUTION

This must be done before the CSIPHY is active.

- (v) Set `CONTROL_CAMERA_PHY_CTRL[4] R_CONTROL_CSI1_RX_SEL`.

CAUTION

This must be done before the CSIPHY is active.

2. CSIPHY and link initialization sequence:
 - (a) Deassert the CSIPHY reset:
 - (i) Set `CSI2_COMPLEXIO_CFG1[30] RESET_CTRL` to 0x1.
 - (b) Assert the ForceRxMode signal:
 - (i) Set `CSI2_TIMING[15] FORCE_RX_MODE_IO1` to 0x1.
 - (c) Power up the CSIPHY:
 - (i) Set `CSI2_COMPLEXIO_CFG1[28:27] PWR_CMD` to 0x1.
 - (d) Check that the state status reaches the ON state:

- [CSI2_COMPLEXIO_CFG1](#)[26:25] PWR_STATUS = 0x1.
- (e) Release the ForceRxMode signal:
 - (i) Set [CSI2_TIMING](#)[15] FORCE_RX_MODE_IO1 to 0x0.
- (f) CSIPHY is initialized and ready/active in CSI1/CCP2B mode.

6.5.3 Programming the CSI1/CCP2B Receiver

This section describes the programming model of the CSI1/CCP2B receiver.

6.5.3.1 Camera ISP CSI1/CCP2B Hardware Setup/Initialization

This section discusses the configuration of the CSI1/CCP2B receiver required before image capture can begin.

6.5.3.1.1 Camera ISP CSI1/CCP2B Reset Behavior

On hardware or software reset of the camera ISP, all registers in the CSI1/CCP2B receiver are reset to their reset values.

6.5.3.2 Camera ISP CSI1/CCP2B Event and Status Checking

When an event occurs, the corresponding bit in the [CCP2_LC01_IRQSTATUS](#) (or [CCP2_LC23_IRQSTATUS](#)) register is set. Each event can be individually masked using the [CCP2_LC01_IRQENABLE](#) register ([CCP2_LC23_IRQENABLE](#)). Masked events are not transmitted to the interrupt lane, but the [CCP2_LC01_IRQSTATUS](#) register (or [CCP2_LC23_IRQSTATUS](#)) is updated.

Events transmitted to the interrupt lane can be mapped to the ARM or DSP by unmasking the ISP_CSIB bit in the ISP_IRQxENABLE (x = 0, 1). Depending on whether the event is mapped to the ARM or DSP register, to clear an event, the following actions are required:

- Clear the event at the CSI1/CCP2B receiver level by writing 1 to the corresponding bit in the [CCP2_LC01_IRQSTATUS](#) register (or [CCP2_LC23_IRQSTATUS](#)).
- Clear the event at ISP level by writing 1 to the corresponding bit ISP_CSI1 in the ISP_IRQxENABLE (x = 0, 1) register.

6.5.3.3 Camera ISP CSI1/CCP2B Register Accessibility During Frame Processing

There are two types of register accesses in the CSI1/CCP2B receiver:

- Shadowed registers:
 - These registers/fields can be read and written (if the field is writable) at any time. However, written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.
 - The shadowed registers are:
 - [CCP2_LCx_CTRL](#)
 - [CCP2_LCx_CODE](#)
 - [CCP2_LCx_STAT_START](#)
 - [CCP2_LCx_STAT_SIZE](#)
 - [CCP2_LCx_SOF_ADDR](#)
 - [CCP2_LCx_EOF_ADDR](#)
 - [CCP2_LCx_DAT_SIZE](#)
 - [CCP2_LCx_DAT_PING_ADDR](#)
 - [CCP2_LCx_DAT_PONG_ADDR](#)
 - [CCP2_LCx_DAT_OFST](#)
- Busy-locked registers:
 - These registers/fields must not be written if the module is busy.

- All register fields not listed as shadowed are busy-writable registers.

6.5.3.4 Camera ISP CSI1/CCP2B Enable/Disable the Hardware

The CSI1/CCP2B receiver is globally controlled by the [CCP2_CTRL](#) register. The bit fields in this register must not be modified when the CSI1/CCP2B interface is active (except [CCP2_CTRL \[0\] IF_EN](#)):

- To activate the CSI1/CCP2B interface:
 - [CCP2_CTRL \[0\] IF_EN](#) = 0x1
 - Data acquisition starts on the following FSC synchronization code. Writing [CCP2_CTRL \[0\] IF_EN](#) = 0x1 resets the output FIFO of the module; the reset is caused by the 0-to-1 edge transition.
- To disable the CSI1/CCP2B interface:
 - [CCP2_CTRL \[0\] IF_EN](#) = 0x0
 - The interface is disabled immediately if [CCP2_CTRL \[3\] FRAME](#) = 0x0.
 - If [CCP2_CTRL \[3\] FRAME](#) = 0x1 and [CCP2_LCx_CTRL\[19\] CRC_EN](#) = 0x0, the interface is disabled after the FEC synchronization code is received.
 - If [CCP2_CTRL\[3\] FRAME](#) = 0x1 and [CCP2_LCx_CTRL\[19\] CRC_EN](#) = 0x1, the interface is disabled only after the 16-bit CRC checksum and 16-bit pad data is received.
 - Before disabling the interface ([IF_EN](#)=0) it is advised to disable all active channels by writing [CCP2_LCx_CTRL\[0\] CHAN_EN](#) = 0x0. Otherwise, if [IF_EN](#) = 0 is set during a vertical blanking period, the reception continues until the FEC synchronization code is received for all active channels.

6.5.3.5 Camera ISP CSI1/CCP2B Select the Signaling Scheme

The [CCP2_CTRL\[1\] PHY_SEL](#) bit selects whether the data/strobe or data/clock signaling scheme is used. See [Table 6-22](#) for the correct settings as a function of the image sensor class. Setting [CCP2_CTRL \[1\] PHY_SEL](#) = 0x1 has no effect if [CCP2_CTRL \[4\] MODE](#) = 0x0.

6.5.3.6 Camera ISP CSI1/CCP2B Control of the PHY

The [CCP2_CTRL \[2\] IO_OUT_SEL](#) bit selects the output mode of the CSI1/CCP2B receiver associated PHY (could be either CSIPHY1 or CSI2PHY2), which must be set to 1 for parallel only.

For information about initializing and configuring the CSIPHY that is associated with the CSI1/CCP2B receiver, see [Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver](#).

6.5.3.7 Camera ISP CSI1/CCP2B Select the Mode: MIPI CSI1 or CCP2B

The [CCP2_CTRL\[4\] MODE](#) bit selects whether the CCP2B module works in MIPI CSI1 or CCP2-compatible mode. Setting [CCP2_CTRL\[4\] MODE](#) = 0x0 disables the CCP2-specific features: data/strobe, CRC, logical channels, RAW6 and RAW7 data formats. The following bits have no effect when [CCP2_CTRL\[4\] MODE](#) = 0x0: [CCP2_CTRL\[1\] PHY_SEL](#), [CCP2_LCx_CTRL\[19\] CRC_EN](#), [CCP2_LCx_CTRL\[0\] CHAN_EN](#) (x = 1 to 3). Furthermore, [CCP2_LCx_CTRL\[7:2\] FORMAT](#) values 8, 9, 10, 12, 13, 14, 17, 18, 21, and 25 have no effect: no data are output. MIPI CSI1 is the default mode of the module.

6.5.3.8 Camera ISP CSI1/CCP2B Burst Settings

The [CCP2_CTRL\[6:5\] BURST](#) bit field forces the burst behavior of the CSI1/CCP2B receiver. The module can be forced to perform single 64-bit requests or bursts of 2x, 4x, and 8x 64 bits. The burst size must never exceed the output FIFO size. The output FIFO size can be read by reading the [CCP2_GNQ\[4:2\] FIFODEPTH](#) bit field.

6.5.3.9 Camera ISP CSI1/CCP2B Debug Mode

Use the [CCP2_CTRL \[7\] DBG_EN](#) bit to enable the debug mode:

- During debug mode, the input comes from the [CCP2_DBG](#) register, not from the CSI1/CCP2B physical interface. The full CSI1/CCP2B receiver functionality can be debugged in debug mode. Full 32-bit

values must always be written to the [CCP2_DBG](#) register.

- The following bits have no effect during debug mode:
 - [CCP2_CTRL](#) [0] IF_EN
 - [CCP2_CTRL](#) [1] PHY_SEL
 - [CCP2_CTRL](#) [2] IO_OUT_SEL
- The following examples apply to the [CCP2_DBG](#) register:
 - Synchronization codes: [CCP2_DBG](#) = 0xFF000000
 - To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, and 0x547, write [CCP2_DBG](#) = 0x01234567 followed by [CCP2_DBG](#) = and 0x89abcdef [CCP2_DBG](#) = 0x76543210.

NOTE: Each write to the [CCP2_DBG](#) register sends a full 32-bit word through the CSI1/CCP2B receiver hardware. When 8- or 16-bit writes are performed to the register, the previous 32-bit value is merged with the newly written one. When the driver writes, for example, 0x01234567 followed by 0x000000FF with [BYTEEN](#) = 0x1 (this write from the MPU subsystem informs that only 8 bits are written), the CSI1/CCP2B receiver pipeline gets 0x01234567 followed by 0x012345FF.

6.5.3.10 Camera ISP CSI1/CCP2B Video Port

- Set the video-port output frequency:
 - [CCP2_CTRL](#) [9:8] VP_OUT_CTRL
 - The video-port output frequency varies from CAM_ICLK to CAM_ICLK/4 MHz. CAM_ICLK is the CSI1/CCP2B receiver functional and interface clock. The reset value selects CAM_ICLK/2.
- [CCP2_CTRL](#) [11] VP_ONLY_EN:
 - Controls whether the video-port output is the only output interface enabled and applies for all channels.
 - When [CCP2_CTRL](#) [11] VP_ONLY_EN = 0x1, the data are output only to the video port; the interface master port is not used. The two parts of the frame (embedded data and pixel data) are output to the video port (instead of pixel data to video port and embedded data to interconnect).
 - The video port outputs the embedded data defined by the [CCP2_LCx_STAT_START](#) and [CCP2_LCx_STAT_SIZE](#) registers without decompression.
 - The video port outputs the pixel data defined by the [CCP2_LCx_DAT_START](#) and [CCP2_LCx_DAT_SIZE](#) registers.
 - The pixel data are decompressed according to the settings of the [CCP2_LCx_CTRL](#) [7:2] FORMAT bit field. [Table 6-59](#) summarizes the behavior of the video port as a function of the [CCP2_LCx_CTRL](#) [7:2] FORMAT bit field.

Table 6-59. Camera ISP CSI1/CCP2B [CCP2_LCx_CTRL](#)[7:2] FORMAT and [CCP2_CTRL](#)[11] VP_ONLY_EN = 1 Settings

CCP2_LCx_CTRL [7:2] Format	Video-Port Behavior
YUV422 + VP or RAW8 + VP	The incoming data are 8 bits. The pixel data are not compressed. The embedded data are transmitted to the CCDC module on 8 bits (DATA[7:0]). The pixel data are not decompressed. The pixel data are transmitted to the CCDC module on 8 bits (DATA[7:0]).
RAW12 + VP	The incoming data are 12 bits. The pixel data are not compressed. The embedded data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are reconstructed in the receiver. The pixel data are transmitted to the CCDC module on 12 bits (DATA[11:0]). The pixel data are not decompressed.

- Control the video-port pixel clock polarity:
 - If `CCP2_CTRL` [12] `VP_CLK_POL` = 0x0, the CSI1/CCP2B receiver module writes the data on the video port on the pixel-clock falling edge. The module connected to the VP samples the data on the pixel clock rising edge.
 - If `CCP2_CTRL` [12] `VP_CLK_POL` = 0x1, the CSI1/CCP2B receiver module writes the data on the video port on the pixel-clock rising edge. The module connected to the VP samples the data on the pixel clock falling edge. [Figure 6-105](#) shows the `CCP2_CTRL.VP_CLK_POL` settings.

Figure 6-105. Camera ISP CSI1/CCP2B `CCP2_CTRL.VP_CLK_POL` Settings

6.5.3.11 Camera ISP CSI1/CCP2B Logical Channels

The CCP2B receiver supports simultaneous logical channels. Each logical channel is controlled independently with its own set of registers. The four sets of registers are identical, but some reset values are different.

The same description applies to all other logical channels. Logical channel LCx means LC0, LC1, LC2, or LC3.

All the registers in this section can be modified at any time. However, the modifications apply only from the start of the following frame.

6.5.3.12 Camera ISP CSI1/CCP2B Controls

The logical channel is controlled by the `CCP2_LCx_CTRL` register.

The logical channel is enabled by setting `CCP2_LCx_CTRL[0] CHAN_EN` = 0x1. By default, all logical channels except logical channel 0 are disabled. Only the pixel data of one logical channel can go to the Video processing hardware; the SOF and EOF lines are always sent to memory through the interconnect interface. Setting `CCP2_LCx_CTRL[0] CHAN_EN` (x=1), `CCP2_LCx_CTRL[0] CHAN_EN` (x=2), or `CCP2_LCx_CTRL[0] CHAN_EN` = 0x1 (x=3) has no effect if `CCP2_CTRL[4] MODE` = 0x0.

6.5.3.13 Camera ISP CSI1/CCP2B Region of Interest

The `CCP2_LCx_CTRL[1] REGION_EN` bit enables the region-of-interest feature (SOF lines, pixel data, and EOF lines):

- If enabled, register settings set the position and size of each region; all data not in a region of interest are ignored.
- If disabled, all data in the frame are output. `CCP2_LCx_CTRL[1] REGION_EN` is set to 0x0 for a JPEG bitstream.

6.5.3.14 Camera ISP CSI1/CCP2B CRC

The CRC can be enabled or disabled with `CCP2_LCx_CTRL[19] CRC_EN`. If the received checksum and the computed checksum do not match, an interrupt is triggered: the corresponding event is `LCx_CRC_IRQ`. Setting `CCP2_LCx_CTRL[19] CRC_EN` = 0x1 has no effect if `CCP2_CTRL[4] MODE` = 0x0.

6.5.3.15 Camera ISP CSI1/CCP2B Destination Format

- Control the destination format:
 - The CSI1/CCP2B receiver reformats received data to store it in memory or to send it to the Videop processing hardware.
 - `CCP2_LCx_CTRL[7:2] FORMAT` controls destination-data format:

- EXP8 = Data expansion to 8 bits, padding with zeros
- EXP16 = Data expansion to 16 bits, padding with alpha or zeros [CCP2_CTRL\[15:8\]](#) ALPHA can be used to set an alpha value. For RGB444 + EXP16:
 - `data_out[31:28]=ALPHA[3:0]` and `data_out[27:16]=RGB444`
 - `data_out[15:12]=ALPHA[3:0]` and `data_out[11:0]=RGB444`
- EXP32 = Data expansion to 32 bits, padding with alpha. [CCP2_CTRL\[15:8\]](#) ALPHA can be used to set an alpha value. For RGB888 + EXP32: `data_out[31:24]=ALPHA[7:0]` and `data_out[23:0]=RGB888`
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
- VP = Output to the Video processing hardware is enabled.

6.5.3.16 Camera ISP CSI1/CCP2B Frame Acquisition

- Program the number of frames that the CSI1/CCP2B receiver acquires:
 - [CCP2_LCx_CTRL \[31:24\]](#) COUNT
 - Writes to the COUNT bit field are controlled by the [CCP2_LCx_CTRL \[16\]](#) COUNT_UNLOCK bit.
 - If COUNT = 0x0, the counter is free-running; frame acquisition lasts until disabled by the programmer. It is the default value.
 - COUNT controls the number of frames to acquire. The values range between 1 and 255. The COUNT value is decremented after each frame received. The software can read this value to acquire the number of frames that remain to be acquired.

After the correct number of frames is received, acquisition is automatically disabled ([CCP2_LCx_CTRL \[0\]](#) CHAN_EN = 0x0) and the COUNT_IRQ interrupt is triggered. The programmer can reenale the acquisition by resetting [CCP2_LCx_CTRL \[0\]](#) CHAN_EN to 0x1.

[CCP2_LCx_CTRL \[17\]](#) PING_PONG indicates whether the PING address ([CCP2_LCx_DAT_PING_ADDR](#)) or PONG address ([CCP2_LCx_DAT_PONG_ADDR](#)) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in [CCP2_CTRL \[0\]](#) IF_EN, the pixel data are written in the PING buffer and [CCP2_LCx_CTRL \[17\]](#) PING_PONG = 0x1 (PONG). After the first FEC synchronization code is received, the pixel data are written in the PONG buffer and [CCP2_LCx_CTRL \[17\]](#) PING_PONG = 0x0 (PING). [CCP2_LCx_CTRL \[17\]](#) PING_PONG toggles after every FEC synchronization code.

6.5.3.17 Camera ISP CSI1/CCP2B Synchronization Codes

The FSC, FEC, LSC, and LEC synchronization codes have default values given by the CCP2B specification. Also, each logical channel is identified by a default identifier.

The [CCP2_LCx_CODE](#) register enables overwriting of the default values: [CCP2_LCx_CODE \[11:8\]](#) FSC, [CCP2_LCx_CODE \[15:12\]](#) FEC, [CCP2_LCx_CODE \[3:0\]](#) LSC, and [CCP2_LCx_CODE \[7:4\]](#) LEC overwrite the 4 LSBs of the 32-bit synchronization codes. The default values should not be modified.

6.5.3.18 Camera ISP CSI1/CCP2B Status Data

The SOF and EOF status lines can be output to memory.

The SOF and EOF status lines always cover full lines. No register settings enable the setting of width.

The [CCP2_LCx_STAT_START](#) register enables the setting of the vertical start position of the SOF and EOF status lines. Because the SOF status line comes first in the CSI1/CCP2B frame, [CCP2_LCx_STAT_START \[11:0\]](#) SOF = 0x0.

The [CCP2_LCx_STAT_SIZE](#) register enables the setting of the numbers of SOF and EOF status lines. If [CCP2_LCx_STAT_SIZE \[11:0\]](#) SOF = 0x0 and [CCP2_LCx_STAT_SIZE \[27:16\]](#) EOF = 0x0, no status data are output.

[Figure 6-106](#) shows the SOF and EOF region settings. The SOF and EOF status lines and the pixel data must not overlap, but can be consecutive. [Figure 6-106](#) shows the SOF and EOF region settings.

Figure 6-106. Camera ISP CSI1/CCP2B SOF and EOF Region Settings

The 32-bit destination address of the SOF status lines is set by the [CCP2_LCx_SOF_ADDR](#) register.

NOTE: The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The SOF lines are packed together at the destination address.

The 32-bit destination addresses of the EOF status lines are set by the [CCP2_LCx_EOF_ADDR](#) register.

NOTE: The destination address must be aligned on a 32-byte boundary; the address 5 LSBs are ignored. The EOF lines are packed together at the destination address.

NOTE: The CSI1/CCP2B receiver does not modify the data in the SOF and EOF status lines. The data are received and written with no modifications.

6.5.3.19 Camera ISP CSI1/CCP2B Pixel Data Region

Pixel data can be output to memory or to the Video processing hardware.

The pixel data region covers full lines. The [CCP2_LCx_DAT_SIZE](#) register sets the horizontal size of the pixel region. The vertical size is expressed in lines.

The [CCP2_LCx_DAT_START](#) register enables the setting of the vertical start position of the pixel data. The vertical start position is expressed in lines.

[Figure 6-107](#) shows the pixel region settings.

- RGB444 + EXP16
- RGB565
- RGB888 + EXP32

For all other data formats, the `CCP2_LCx_DAT_OFST` register is ignored (equivalent to `CCP2_LCx_DAT_OFST = 0x0`).

The destination data format is set with the `CCP2_LCx_CTRL [7:2] FORMAT` bit field.

For the PING frame:

- @Line0 = `CCP2_LCx_DAT_PING_ADDR`
- @Line1 = @Line0 + `CCP2_LCx_DAT_OFST`
- @Line2 = @Line1 + `CCP2_LCx_DAT_OFST`

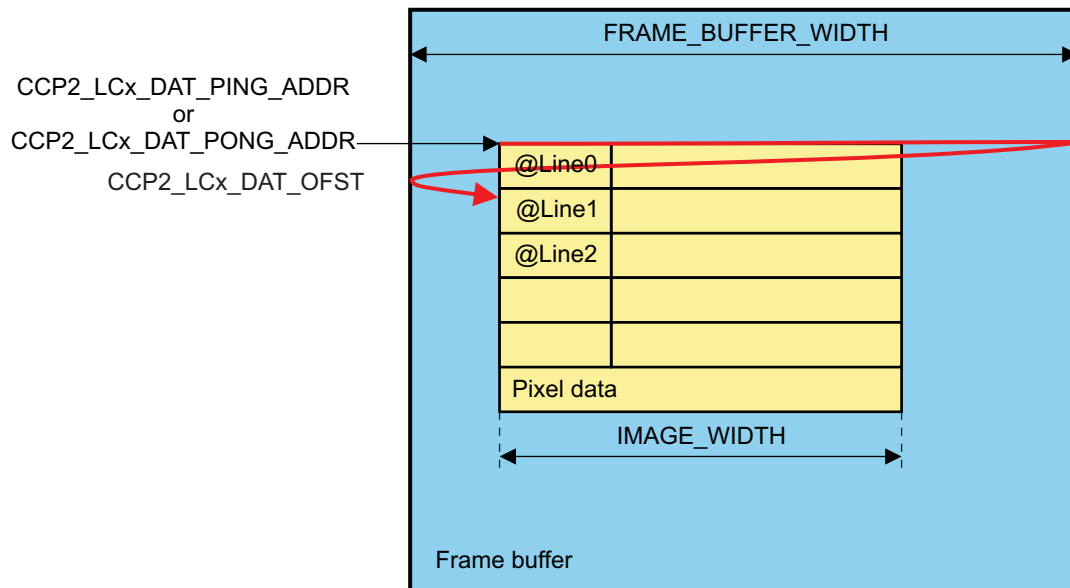

For the PONG frame:

- @Line0 = `CCP2_LCx_DAT_PONG_ADDR`
- @Line1 = @Line0 + `CCP2_LCx_DAT_OFST`
- @Line2 = @Line1 + `CCP2_LCx_DAT_OFST`

When `CCP2_LCx_DAT_OFST = 0x0`, the lines are written contiguously in memory. The destination pitch enables 2D transfers; it is required to write the pixel data directly in the frame buffer, for instance.

In such cases, `CCP2_LCx_DAT_OFST = FRAME_BUFFER_WIDTH`. Figure 6-108 shows the pixel data settings.

Figure 6-108. Camera ISP CSI1/CCP2B Pixel Data Destination Settings

camisp-203

6.5.3.20 Camera ISP CSI1/CCP2B Memory Read Channel

6.5.3.20.1 Camera ISP CSI1/CCP2B Write Data From Sensor to Memory

Data can be captured from the sensor using any logical channel. To keep the native data format, the channel format must be set to YUV422 little-endian format.

6.5.3.20.2 Camera ISP CSI1/CCP2B Read Data from Memory

By default, the memory read channel is disabled. Before the memory read channel can be enabled ([CCP2_LCM_CTRL](#) [0] CHAN_EN = 1), all logical channels must be disabled ([CCP2_CTRL](#) [0] IF_EN = 0) and required registers must be configured.

When the [CCP2_CTRL](#) [3] FRAME bit is set, software must wait until disabling of the physical interface is effective before enabling the memory read channel.

The SBL image data read port is shared by the PREVIEW and CSI1/CCP2B receiver modules. The read port must be affected to the CSI1/CCP2B receiver module by writing 1 to the [ISP_CTRL](#)[27] SBL_SHARED_RPORTA bit. The programmer must ensure that the PREVIEW module does not use this port before switching to the CSI1/CCP2B module.

The burst size must be configured to 32 x 64-bit bursts, using the [CCP2_LCM_CTRL](#) [7:5] BURST_SIZE register.

Firmware must then configure the source data format, location, and framing. In addition to the [CCP2_LCM_HSIZE](#) [11:0] SKIP and [CCP2_LCM_HSIZE](#) [27:16] COUNT registers, the firmware must specify the amount of data to be fetched from memory. This value is set in 64-bit word steps and must be a multiple of 32 bytes (four words of 64 bits). The value is computed with the following formula:

$$\text{HWORDS} = 4 \times \text{ceil}((\text{SKIP} + \text{COUNT}) \times \text{bits_per_pixel}) / (8 \times 32) \quad (3)$$

The [CCP2_LCM_SRC_ADDR](#) and [CCP2_LCM_SRC_OFST](#) registers must be aligned on 32-byte boundaries for correct operation. For best performance, both registers must be aligned on 256-byte boundaries.

Example:

- [CCP2_LCM_CTRL](#) [7:5] BURST_SIZE is set to 32 x 64 bits
- [CCP2_LCM_HSIZE](#) [11:0] SKIP = 0
- [CCP2_LCM_HSIZE](#) [27:16] COUNT = 1000
- [CCP2_LCM_CTRL](#) [23] SRC_PACK = YES
- [CCP2_LCM_CTRL](#) [18:16] SRC_FORMAT = RAW6
- [CCP2_LCM_PREFETCH](#) [13:3] HWORDS = 96 (=94)

Setting the size to 94 produces the following burst sequence: 32, 32, 16, 8, and 4 (5 interconnect requests). However, when it is set to 96, the burst sequence is 32, 32, and 32 (3 interconnect requests).

By default, only MIPI CSI1 data formats are supported. To support CCP2 formats, [CCP2_CTRL](#) [4] MODE must be set by firmware.

Data is sent to memory when [CCP2_LCM_CTRL](#) [2] DST_PORT = 1; otherwise, it is sent to the video port. It is not possible to send data to the video port and memory concurrently. If data are sent to the video port, its clock frequency is selected with the [CCP2_CTRL](#) [31:15] FRACDIV bit field. Otherwise, the [CCP2_CTRL](#) [31:15] FRACDIV bit field is ignored.

NOTE: In a given scenario where data is sent to the video port and further down to ISP (CCDC and/or RSZ) to be processed, it is possible for CCP2 to stall the image signal processor by feeding too much data to CCDC and/or RSZ. At that time, the CCDC/RSZ FIFO overflow interrupt is raised. To prevent the processor from stalling, the VP clock must be lowered from [CCP2_CTRL](#)[31:15] FRACDIV.

The [CCP2_LCM_CTRL](#) [4:3] READ_THROTTLE register can be used to reduce the bandwidth in memory-to-memory operation to prevent system overload. It has no effect when data are sent to the video port.

If the memory write port is used, the destination format and address must be configured.

Then the memory channel is enabled by setting [CCP2_LCM_CTRL](#) [0] CHAN_EN = 1. After processing a full frame, this bit is automatically cleared by hardware and an EOF event is triggered.

6.5.4 Programming the CSI2 Receiver

6.5.4.1 Camera ISP CSI2 Enabling the Interface

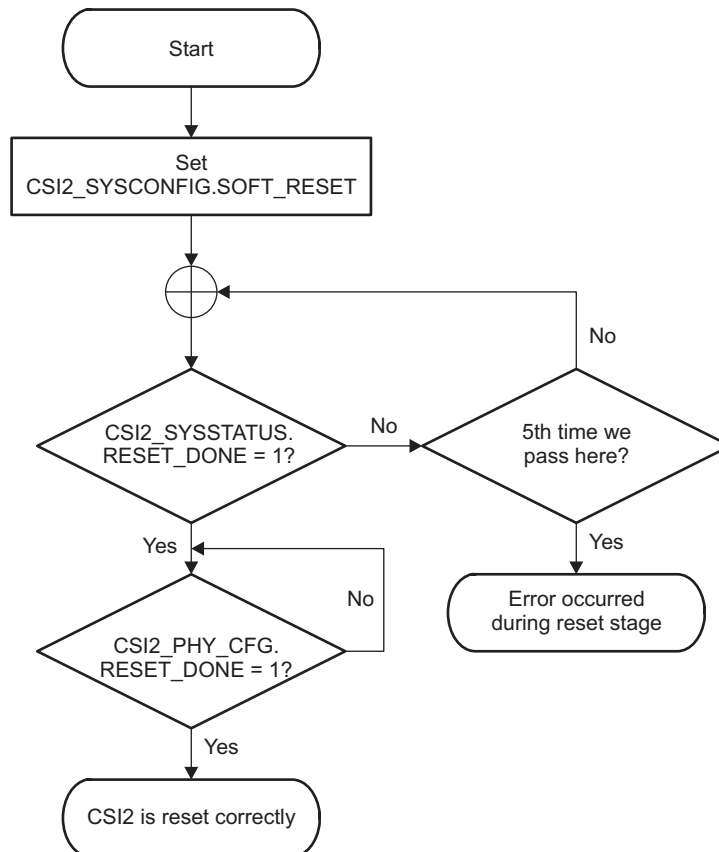

The CSI2 interface is clocked by CSI2_96_FCLK, which is enabled by setting the PRCM.CM_FCLKEN_CAM[1] EN_CSI2 bit register to 1.

6.5.4.2 Camera ISP CSI2 Reset Management

The CSI2 receiver accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the PHY and has the same effect as a hardware reset.

Figure 6-109 shows how to reset the CSI2 globally.

Figure 6-109. Camera ISP CSI2 Receiver Global Reset Flow Chart

camisp-252

NOTE: CSI2_PHY_CFG.RESET_DONE is set to 1 only after the CSI2 receiver, CSI2 PHYs, and external camera sensor are initialized.

NOTE: Before setting the software reset bit to 1 in the [CSI2_SYSCONFIG](#) register, the user must have access to a CSI2 receiver register.

NOTE: The CSI2 protocol engine provides only the configuration bus clock when PHY registers are accessed. However, the PHY needs at least three configuration bus clock cycles (L4 interconnect clock) to come out of the reset state. Therefore, software must perform a dummy read of a PHY register (32 configuration bus clock pulses) to complete the PHY reset sequence.

6.5.4.3 Camera ISP CSI2 Enable Video/Picture Acquisition

To start a video/picture acquisition, perform the following steps:

1. Reset the CSI2 receiver module (see [Section 6.5.4.2, Reset Management](#)).
 2. Configure the module power management: Set the [CSI2_SYSCONFIG\[13:12\] MSTANDBY_MODE](#) bit field to 0x2 so the module tries to enter smart-standby mode during the vertical blanking period. The [CSI2_SYSCONFIG\[0\] AUTO_IDLE](#) bit field keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity
 3. Configure the interrupt generation as required using the [CSI2_IRQSTATUS](#) and [CSI2_IRQENABLE](#) registers. To enable context and/or PHY event reporting, enable the corresponding bit field in the [CSI2_IRQENABLE](#) register. If the enable bit is at 0, logging is still effective if an event occurs but is not reported to a higher level.
 4. Configure the PHY interrupt generation as required using the [CSI2A_PHY_IRQSTATUS](#) and [CSI2_COMPLEXIO1_IRQENABLE](#) registers. If the enable bit is at 0, logging is still effective if an event occurs but is not reported to a higher level.
 5. Initialize the PHY (see [Section 6.5.2.1, Camera ISP CSIPHY Initialization for Work With CSI2 Receiver](#)).
 6. Set the [CSI2_CTRL\[2\] ECC_EN](#) bit to 1 to activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error).
 7. Start the CSI2 receiver by setting the [CSI2_CTRL\[0\] IF_EN](#) bit to 1.
 8. Configure the different contexts to be used (up to eight):
 - (a) Link the context to a virtual channel and a data type (see [Section 6.5.4.7, Linking a Context to a Virtual Channel and a Data Type](#)).
 - (b) Set the [CSI2_CTX_CTRL1\[26:23\] FEC_NUMBER](#) bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see [Section 6.4.3.8, DMA Engine](#).
 - (c) Keep the [CSI2_CTX_CTRL1\[15:8\] COUNT](#) bit field and the [CSI2_CTX_CTRL1\[4\] COUNT_UNLOCK](#) bit at their reset values (0x0 and 0, respectively) to capture an infinite number of frames (until the interface or the context is disabled).
 - (d) Set the [CSI2_CTX_CTRL1\[5\] CS_EN](#) bit to enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the [CSI2_CTX_IRQSTATUS\[5\] CS_IRQ](#) bit).
 - (e) Configure the DMA engine for the current channel:
 - Configure the [CSI2_CTX_DAT_PING_ADDR\[31:5\] ADDR](#) bit field to set the ping frame address in memory.
 - Configure the [CSI2_CTX_DAT_PONG_ADDR\[31:5\] ADDR](#) bit field to set the pong frame address in memory. If not using a double-buffer mechanism, the ping and pong addresses must be equal so that all frames are stored at the same memory address).
 - Set the [CSI2_CTX_DAT_OFST\[15:5\] OFST](#) bit field to 0x0, so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal).
-
- NOTE:** Addresses given for PING and PONG frames are virtual addresses. Address translations are made on the camera MMU and on the Circular Buffer. For more information about the camera MMU module, see [Chapter 15, Memory Management Units](#).
-
- (f) Keep the [CSI2_CTX_CTRL3\[29:16\] ALPHA](#) bit field at its reset value (0x0) for RGB padding.
9. Enable the contexts to be used by setting the [CSI2_CTX_CTRL1\[0\] CTX_EN](#) bit to 1.

6.5.4.4 Camera ISP CSI2 Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by writing 0 to the [CSI2_CTX_CTRL1\[0\] CTX_EN](#) bit. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.

- Disable the CSI2 receiver interface by writing 0 to the [CSI2_CTRL\[0\] IF_EN](#) bit. This can have an immediate effect if the [CSI2_CTRL\[3\] FRAME](#) bit is 0, or it can be effective after all the enabled contexts receive the FEC if the [CSI2_CTRL\[3\] FRAME](#) bit is 1.

6.5.4.5 Camera ISP CSI2 Capture a Finite Number of Frames

The CSI2 receiver module can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the following steps:

1. Write 1 to the [CSI2_CT_x_CTRL1\[4\] COUNT_UNLOCK](#) bit to enable a write to the COUNT bit field.
2. Set the bit field to the number of frames the CSI2 receiver must capture. Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture.
3. Write 0 to the [CSI2_CT_x_CTRL1\[4\] COUNT_UNLOCK](#) bit to disable a write to the COUNT bit field.

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. The software reads the COUNT bit field to know how many frames still must be captured.

The COUNT bit can be updated during capture if the COUNT_UNLOCK is set to 1.

6.5.4.6 Camera ISP CSI2 Configure a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the [CSI2_CT_x_CTRL3\[15:0\] LINE_NUMBER](#) bit field. The event can be generated once or multiple times per frame, depending on the [CSI2_CT_x_CTRL1\[1\] LINE_MODULO](#) bit value:

- If the LINE_MODULO bit = 0, the event is generated when the line number corresponding to the LINE_NUMBER bit field is received.
- If the LINE_MODULO bit = 1, the event is generated when the line number received corresponds to a multiple of the LINE_NUMBER value (LINE_NUMBER is used as a modulo).

6.5.4.7 Camera ISP CSI2 Linking a Context to a Virtual Channel and a Data Type

The CSI2 receiver supports eight contexts and the CSI2 protocol defines four virtual channels. Therefore, a CSI2 receiver context can be associated with a virtual channel and a data type. Virtual channels are defined by a 2-bit field. Valid data types for the CSI2 receiver with their associated values are described in [Table 6-60](#).

Table 6-60. Camera ISP CSI2 Receiver-Supported Data Types

Value	Data Type
0x0	Others
0x12	Embedded 8-bit nonimage data
0x18	YUV420 8-bit
0x19	YUV420 10-bit
0x1A	YUV420 8-bit legacy
0x1C	YUV420 8-bit + CSPS
0x1D	YUV420 10-bit + CSPS
0x1E	YUV422 8-bit
0x1F	YUV422 10-bit
0x22	RGB565
0x24	RGB888
0x28	RAW6
0x29	RWA7
0x2A	RAW8
0x2B	RAW10
0x2C	RAW12
0x2D	RAW14
0x33	RGB666 + EXP32_24

0x3AA	RAW8 DPCM 12 + VP

For each context, a [CSI2_CTx_CTRL2](#) register defines with which channel and data type the context is associated:

- The VIRTUAL_ID field defines the associated virtual ID transported by the CSI2 protocol from the camera sensor.
- The FORMAT field defines the associated data type. The data type is a combination of the data type transported by the CSI2 protocol and the type of storage in memory. A given data type (RGB888) can be stored in memory in different ways (RGB888 or RGB888 + EXP32). Therefore, the FORMAT field also defines the way DMA stores data in memory.

For example, for the current context to capture a frame from virtual channel 2 and data type RAW12 with data expansion (RAW12 + EXP16), write the value 0x10AC (0x2 11 + 0xAC) in the 16 LSBs of the [CSI2_CTx_CTRL2](#) register.

6.5.4.8 Camera ISP CSI2 Progressive and Interleaved Frame Configuration

The CSI2 receiver can treat both progressive and interlaced frames. There is no progressive or interleaved mode, but the [CSI2_CTx_CTRL1\[23:16\] FEC_NUMBER](#) field controls the number of FECs before swapping to the other (ping or pong) buffer. Therefore, two modes are possible:

- **FEC_NUMBER = 1:** This is equivalent to progressive mode. After a FEC on the context, the current buffer is switched (ping to pong or pong to ping). The image in the memory buffer consists of one transmitted frame.
- **FEC_NUMBER != 1:** The current buffer is switched (ping to pong or pong to ping) after the **FEC_NUMBER** FEC is received for the context. The image in the memory buffer consists of the **FEC_NUMBER** transmitted frame.

For more information about how data is stored in memory through the DMA, see [Section 6.4.3.8, DMA Engine](#).

NOTE: If **FEC_NUMBER != 1**, the camera sensor must send the line number information with the current line. Otherwise, the CSI2 receiver cannot calculate each line address.

6.5.5 Programming the Timing CTRL Module

NOTE: All the following settings must be done before enabling the timing control module.

6.5.5.1 Camera ISP Timing CTRL Timing Generator

The **cam_xclk_a** clock frequency is set through the [TCTRL_CTRL\[4:0\] DIVA](#) bit field. The **cam_xclk_b** clock frequency is set through the [TCTRL_CTRL\[9:5\] DIVB](#) bit field. One can change the divisor values at any time.

For divisor values 0, 1, and 31, the divider is not enabled. For all other values:

- `cam_xclka = cam_mclk/TCTRL_CTRL[4:0] DIVA`
- `cam_xclkb = cam_mclk/TCTRL_CTRL[9:5] DIVB`

6.5.5.2 Camera ISP Timing CTRL Camera-Control Signal Generator

Enabling of the SHUTTER, PRESTROBE or STROBE signals generation and activates the counters:

- `TCTRL_CTRL[21] SHUTEN = 1`
- `TCTRL_CTRL[22] PSTRBEN = 1`
- `TCTRL_CTRL[23] STRBEN = 1`

Two configurations apply:

- The control signals are based on the vertical synchronization information coming from the camera module or from the externally generated `cam_global_reset` signal.
- The control signals are based on the internally generated `cam_global_reset`.

6.5.5.2.1 Camera ISP Timing CTRL Vertical Synchro-Based Control-Signal Generation or Externally-Generated `cam_global_reset`

Before enabling the control-signal generation, the following registers must be set:

- Select the input that triggers the control signals. The trigger signal can come from the PARALLEL, CSI2A, CSI2C or CSI1/CCP2B interface, or the externally-generated `cam_global_reset` signal.
 - `TCTRL_CTRL[28:27] INSEL`
- The signal must be set to INPUT:
 - `TCTRL_CTRL[31] GRESETDIR = 0x0`
 - Writes to `TCTRL_CTRL[29] GRESETEN` bit do not trigger the PRESTROBE, STROBE, and SHUTTER signals, and do not generate the `cam_global_reset` signal.
- The following bits are cleared automatically to 0 after the signal assertion:
 - `TCTRL_CTRL[21] SHUTEN`
 - `TCTRL_CTRL[22] PSTRBEN`
 - `TCTRL_CTRL[23] STRBEN`
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and `cam_global_reset` signals. The signals can be active high or active low:
 - `TCTRL_CTRL[24] SHUTPOL`
 - `TCTRL_CTRL[26] STRBPSTRBPOL`
 - `TCTRL_CTRL[30] GRESETPOL`
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
 - `TCTRL_CTRL[18:10] DIVC`

The clock is set by `CNTCLK = cam_mclk/TCTRL_CTRL[18:10] DIVC`. The possible values are 0 to 511. Setting `DIVC = 0` disables the CNTCLK clock generation.
- The frame counters are set with (possible values are 0 to 63 frames):
 - `TCTRL_FRAME[5:0] SHUT`
 - `TCTRL_FRAME[11:6] PSTRB`
 - `TCTRL_FRAME[17:12] STRB`

NOTE: If the value is 0, the timing control module does not delay any frame in input.

- The delay counters are set with:
 - `TCTRL_SHUT_DELAY`
 - `TCTRL_PSTRB_DELAY`

- [TCTRL_STRB_DELAY](#)

The possible values are 0 to $2^{25} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$ ([TCTRL_CTRL\[18:10\] DIVC = 511](#)).

- The signal durations are set with:

- [TCTRL_SHUT_LENGTH](#)
- [TCTRL_PSTRB_LENGTH](#)
- [TCTRL_STRB_LENGTH](#)

The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$ ([TCTRL_CTRL\[18:10\] DIVC = 511](#)).

6.5.5.2.2 Camera ISP Timing CTRL Internally-Generated cam_global_reset-Based Control-Signal Generation

Before enabling the cam_global_reset control-signal generation by writing [TCTRL_CTRL\[29\] GRESETEN = 1](#), the following registers must be set:

NOTE: Setting [TCTRL_CTRL\[21\] SHUTEN](#), [TCTRL_CTRL\[22\] PSTRBEN](#), [TCTRL_CTRL\[23\] STRBEN](#), and [TCTRL_CTRL\[29\] GRESETEN](#) to 1 simultaneously leads to unpredictable behavior. The [TCTRL_CTRL\[21\] SHUTEN](#), [TCTRL_CTRL\[22\] PSTRBEN](#), [TCTRL_CTRL\[23\] STRBEN](#) must be set before [TCTRL_CTRL\[29\] GRESETEN](#) is enabled.

- The signal must be set to OUTPUT:
 - [TCTRL_CTRL\[31\] GRESETDIR = 0x1](#)
 - Vertical synchronization events do not trigger the PRESTROBE, STROBE, and SHUTTER signals.
- The following bits are cleared automatically to 0 after the signal assertion:
 - [TCTRL_CTRL\[21\] SHUTEN](#)
 - [TCTRL_CTRL\[22\] PSTRBEN](#)
 - [TCTRL_CTRL\[23\] STRBEN](#)
 - [TCTRL_CTRL\[29\] GRESETEN](#)
- The following bits set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam_global_reset signals. The signals can be active high or active low:
 - [TCTRL_CTRL\[24\] SHUTPOL](#)
 - [TCTRL_CTRL\[26\] STRBPSTRBPOL](#)
 - [TCTRL_CTRL\[30\] GRESETPOL](#)
- The following bit sets the clock divisor value, which generates the CNTCLK clock:
 - [TCTRL_CTRL\[18:10\] DIVC](#)

The clock is set by $\text{CNTCLK} = \text{cam_mclk} / \text{TCTRL_CTRL}[18:10] \text{ DIVC}$. The possible values are 0 to 511. Setting $\text{DIVC} = 0$ disables the CNTCLK clock generation.
- The frame counters bit fields are ignored:
 - [TCTRL_FRAME\[5:0\] SHUT](#)
 - [TCTRL_FRAME\[11:6\] PSTRB](#)
 - [TCTRL_FRAME\[17:12\] STRB](#)
- The delay counters are set with:
 - [TCTRL_SHUT_DELAY](#)
 - [TCTRL_PSTRB_DELAY](#)
 - [TCTRL_STRB_DELAY](#)

The possible values are 0 to $2^{25} - 1$ cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$ ([TCTRL_CTRL\[18:10\] DIVC = 511](#)).
- The signal durations are set with:
 - [TCTRL_SHUT_LENGTH](#)

- TCTRL_PSTRB_LENGTH
- TCTRL_STRB_LENGTH

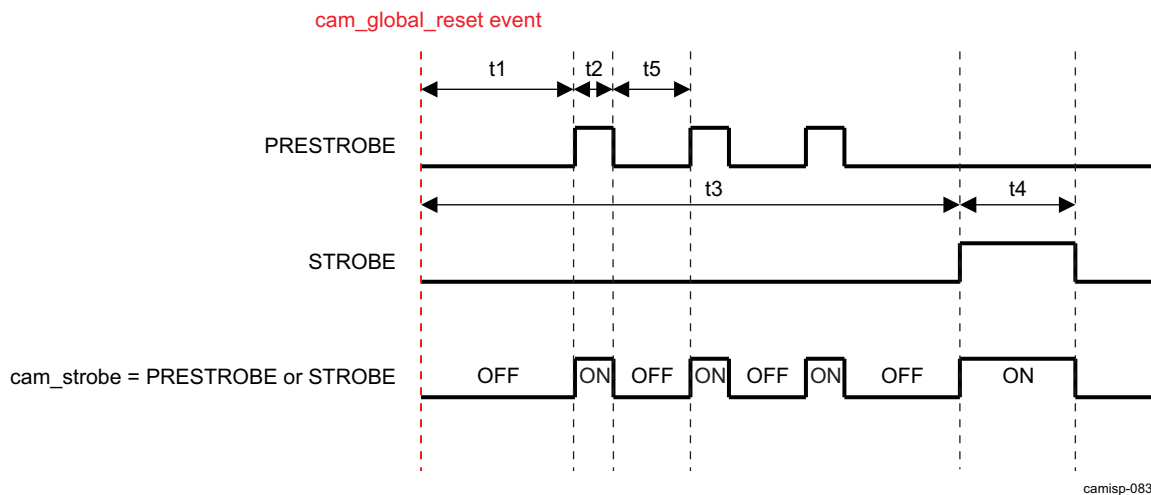

The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$ (TCTRL_CTRL[18:11] DIVC = 511).

- The cam_global_reset assertion time is set by TCTRL_GRESET_LENGTH. The possible values are 0 to 224 -1 cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{24} - 1) \times 2.366 \text{ s} = 39.69 \text{ s}$ (TCTRL_CTRL[18:11] DIVC = 511).

6.5.5.2.3 Camera ISP Timing CTRL STROBE and PRESTROBE Signal Generation for Red-Eye Removal

The STROBE and PRESTROBE signal generation enables a strobe flash for red eye removal. The process is shown in Figure 6-110. The dotted line corresponds to known timings from which the delay counters start decreasing: cam_global_reset event.

Figure 6-110. cam_strobe Signal-Generation for Red-Eye Removal

- t1: Set by the TCTRL_PSTRB_DELAY register
- t2: set by the TCTRL_PSTRB_LENGTH register
- t5: set by the TCTRL_PSTRB_REPLAY[24:0] DELAY bit field. The number of times the pulse is repeated is controlled by the TCTRL_PSTRB_REPLAY [31:25] COUNTER register. In the former example, TCTRL_PSTRB_REPLAY [31:25] COUNTER = 2.
 - The possible delay values are 0 to $2^{25} - 1$ cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 2.366 \text{ s} = 79 \text{ s}$ (TCTRL_CTRL[18:11] DIVC = 511).
 - The possible count values are 0 to 127 additional pulses.
- t3: Set by the TCTRL_STRB_DELAY register
- t4: Set by the TCTRL_STRB_LENGTH register

6.5.6 Programming the CCDC

This section discusses issues related to the software control of the CCDC. It lists which registers are required to be programmed in different modes, and describes how to enable and disable the CCDC, how to check the status of the CCDC, the different register access types, and programming constraints.

6.5.6.1 Camera ISP CCDC Hardware Setup/Initialization

This section discusses the configuration of the CCDC required before image processing can begin.

6.5.6.1.1 Camera ISP CCDC Reset Behavior

On hardware reset of the camera ISP, all registers in the CCDC are reset to their reset values.

6.5.6.1.2 Camera ISP CCDC Register Setup

Before enabling the CCDC, the hardware must be correctly configured through register writes. [Table 6-61](#) identifies the register parameters that must be programmed before enabling the CCDC.

Table 6-61. Camera ISP CCDC Required Configuration Parameters

Function	Configuration Required
External pin signal configuration	CCDC_SYN_MODE[0] VDHDOUT CCDC_SYN_MODE[16] VDHDEN CCDC_SYN_MODE[2] VDPOL CCDC_SYN_MODE[3] HDPOL CCDC_SYN_MODE[7] FLDMODE CCDC_SYN_MODE[1] FLDOUT CCDC_SYN_MODE[4] FLDPOL CCDC_SYN_MODE [5] EXWEN CCDC_SYN_MODE[6] DATAPOL CCDC_CFG[15] VDLC = 1 ISP_CTRL[3:2] PAR_BRIDGE ISP_CTRL[7:6] SHIFT ISP_CTRL[4] PAR_CLK_POL
Input mode	CCDC_REC656IF[0] R656ON CCDC_SYN_MODE[13 :12] INPMOD
Color pattern	CCDC_COLPTN
Black compensation	CCDC_BLKCMP
Faulty-pixel correction	CCDC_FPC[15] FPCEN
Data-path configuration	CCDC_FMTCFG[15] VPEN CCDC_SYN_MODE[18] VP2SDR CCDC_SYN_MODE[17] WEN CCDC_SYN_MODE[19] SDR2RSZ
Lens-shading compensation	CCDC_LSC_CONFIG[0] ENABLE

[Table 6-62](#) identifies additional configuration requirements depending on whether the corresponding condition is met.

[Table 6-62](#) can be read as: if (**Condition** is TRUE), then **Configuration Required** parameters must be programmed.

Table 6-62. Camera ISP CCDC Conditional Configuration Parameters

Function	Condition	Configuration Required
VD/HD set as outputs	CCDC_SYN_MODE[0] VDHDOUT = 0x1	CCDC_HD_VD_WID CCDC_PIX_LINES
Interlaced fields	CCDC_SYN_MODE[7] FLDMODE = 0x1	CCDC_CFG[7:6] FIDMD
External WEN	CCDC_SYN_MODE[5] EXWEN = 0x1	CCDC_CFG[8] WENLOG

Lens-shading compensation	CCDC_LSC_CONFIG [0] ENABLE	CCDC_LSC_CONFIG CCSC_LSC_INITIAL CCDC_LSC_TABLE_BASE CCDC_LSC_TABLE_OFFSET

6.5.6.1.3 Camera ISP CCDC Pixel Selection (Framing) Register Dependencies

There are three locations in the data flow where the valid frame data can be defined:

- Data formatter input pixel selection
- Video port output pixel selection
- Output formatter pixel selection

Care must be taken to ensure that the frame definitions correspond to the output of the upstream frame definitions. When the video port is enabled, [CCDC_VP_OUT](#)[30:17] VERT_NUM must be less than [CCDC_FMT_VERT](#)[12:0] FMTLNV.

Two data paths through the CCDC affect the programming of the pixel-selection registers, depending on the value of the [CCDC_SYN_MODE](#)[18] VP2SDR bit:

- VP2SDR = 0: The input data bypasses the data formatter/video port. In this case, only the memory output frame parameters apply. This data path is represented by the white arrow in [Figure 6-111](#).
- VP2SDR = 1: The input data passes through the data formatter/video port. In this case, both data formatter frame definitions apply to the video-port output, and all three frame definitions apply to the memory output. This data path is represented by the green shaded arrow in [Figure 6-111](#).

6.5.6.2 Camera ISP CCDC Enable/Disable Hardware

All required registers mentioned in the previous section must be programmed before setting the `CCDC_PCR[0]` ENABLE bit.

The CCDC always operates in continuous mode. In other words, after enabling the CCDC, it processes sequential frames until the ENABLE bit is cleared by software. When this happens, the frame being processed completes before the CCDC is disabled.

When the CCDC is in master mode (HS/VS signals set to outputs), fetching and processing of the frame begin immediately on setting the `CCDC_PCR[0]` ENABLE bit.

When the CCDC is in slave mode (HS/VS signals set to inputs), processing of the frame depends on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the CCDC must be enabled before data transmission from the external device. In this way, the CCDC waits for data from the external device.

On setting the `CCDC_FPC[15]` FPCEN bit, the CCDC begins to fetch and buffer the faulty-pixel table from memory. If faulty-pixel correction is used, the `CCDC_FPC[15]` FPCEN bit must be set before the `CCDC_PCR[0]` ENABLE bit, but after the faulty-pixel table is placed in memory and the `CCDC_FPC[14:0]` FPNUM and `CCDC_FPC_ADDR` registers are set.

6.5.6.3 Camera ISP CCDC Events and Status Checking

The CCDC can generate three different interrupts: `CCDC_VD0_IRQ`, `CCDC_VD1_IRQ`, and `CCDC_VD2_IRQ`.

The `CCDC_SYN_MODE[16]` VDHEN bit must be enabled to receive any of the CCDC `CCDC_VDx_IRQ` interrupts.

6.5.6.3.1 Camera ISP CCDC Interrupts

The CCDC module has three programmable events: `CCDC_VD0_IRQ`, `CCDC_VD1_IRQ`, and `CCDC_VD2_IRQ`, and one error event `CCDC_ERR_IRQ`. Event generation is described in [Section 6.5.6.3.2, `CCDC_VD0_IRQ` and `CCDC_VD1_IRQ` Interrupts](#), and [Section 6.5.6.3.3, `CCDC_VD2_IRQ` Interrupt](#).

CCDC module events can be mapped to the ARM or the DSP:

- The `CCDC_VD0_IRQ`, `CCDC_VD1_IRQ`, `CCDC_VD2_IRQ`, and `CCDC_ERR_IRQ` bits in the `ISP_IRQ0ENABLE` register control whether the CCDC module events trigger an interrupt to the ARM. The `ISP_IRQ0STATUS` register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the `ISP_IRQ0STATUS` register. To clear the `CCDC_ERR_IRQ` interrupt, clear the `CCDC_FPC[16]` FPERR bit before clearing the `ISP_IRQ0STATUS[11]` `CCDC_ERR_IRQ` bit.
- The `CCDC_VD0_IRQ`, `CCDC_VD1_IRQ`, `CCDC_VD2_IRQ`, and `CCDC_ERR_IRQ` bits in the `ISP_IRQ1ENABLE` register control whether the CCDC module events trigger an interrupt to the DSP. The `ISP_IRQ1STATUS` register indicates which event(s) triggered the interrupt. An event is cleared by writing a 1 in its corresponding bit in the `ISP_IRQ1STATUS` register. To clear the `CCDC_ERR_IRQ` interrupt, clear the `CCDC_FPC[16]` FPERR bit before clearing the `ISP_IRQ1STATUS[11]` `CCDC_ERR_IRQ` bit.

6.5.6.3.2 Camera ISP CCDC `CCDC_VD0_IRQ` and `CCDC_VD1_IRQ` Interrupts

As shown in [Figure 6-112](#), the `CCDC_VD0_IRQ` and `CCDC_VD1_IRQ` interrupts occur relative to the VS pulse. The trigger timing is selected by using the `CCDC_SYN_MODE[2]` VDPOL setting. `CCDC_VD0_IRQ` and `CCDC_VD1_IRQ` occur after receiving the number of horizontal lines (HS pulse signals) set in the `CCDC_VDINT[30:16]` VDINT0 and `CCDC_VDINT[14:0]` VDINT1 register fields, respectively.

NOTE: In the case of BT.656 input mode, there is VS at the beginning of each field. Therefore, there are two interrupts for each frame (one for each field).

If `CCDC_SYN_MODE[2]` `VDPOL` is 0, the `CCDC_VD0_IRQ` and `CCDC_VD1_IRQ` HS counters begin counting HS pulses from the rising edge of the external `VS`, as shown in [Figure 6-112](#).

Figure 6-112. Camera ISP CCDC `CCDC_VD0_IRQ/CCDC_VD1_IRQ` Interrupt Behavior When `VDPOL = 0`

If `CCDC_SYN_MODE[2]` `VDPOL` is 1, the `CCDC_VD0_IRQ` and `CCDC_VD1_IRQ` HS counters begin counting HS pulses from the falling edge of the external `VS`.

Figure 6-113. Camera ISP CCDC `CCDC_VD0_IRQ/CCDC_VD1_IRQ` Interrupt Behavior When `VDPOL = 1`

6.5.6.3.3 Camera ISP CCDC `CCDC_VD2_IRQ` Interrupt

In addition to the `CCDC_VD0_IRQ` and `CCDC_VD1_IRQ` interrupts, the CCDC has an interrupt called `CCDC_VD2_IRQ`. This interrupt always occurs at the falling edge of the `WEN` signal (through external pin). There are no registers in the CCDC module to configure this interrupt (see [Figure 6-114](#)).

Figure 6-114. Camera ISP CCDC `CCDC_VD2_IRQ` Interrupt Behavior

6.5.6.3.4 Camera ISP CCDC Status Checking

The `CCDC_PCR[1]` `BUSY` status bit is set when the start of frame occurs (if the `CCDC_PCR[0]` `ENABLE` bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The `CCDC_PCR[1]` `BUSY` status bit may be polled to determine end-of-frame status.

The `CCDC_FPC[16]` `FPERR` status bit is set when faulty-pixel data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

6.5.6.4 Camera ISP CCDC Register Accessibility During Frame Processing

There are three types of register access in the CCDC:

- Shadowed registers: In the CCDC, two register fields are shadowed in different ways. Shadowed registers can be read and written at any time, but the written values take effect (are latched) only at certain times, based on some event. Reads return the most recent write, even though the settings are not used until the specific event occurs. The shadowed registers are:
 - `CCDC_PCR[0]` `ENABLE`
 - Written values take effect only at the start of a frame event (rising edge of `VD` if `CCDC_SYN_MODE[2]` `VDPOL` is positive, or falling edge of `VD` if `CCDC_SYN_MODE[2]` `VDPOL` is negative).
 - `CCDC_SDR_ADDR`

- When [CCDC_CFG\[15\]](#) VDLC is set to 0, written values take effect only at the start of a frame event (rising edge of VD if [CCDC_SYN_MODE\[2\]](#) VDPOL is positive, or falling edge of VD if [CCDC_SYN_MODE\[2\]](#) VDPOL is negative). When [CCDC_CFG\[15\]](#) VDLC is set to 1, written values take effect only at the start of the frame being output to memory (when the input has reached the [CCDC_HORZ_INFO\[30:16\]](#) SPH pixel of the [CCDC_VERT_START\[30:16\]](#) SLV0 or [CCDC_VERT_START\[14:0\]](#) SLV1 line of each field).
- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.
All register fields in the CCDc not formerly listed as shadowed or below as optionally shadowed/busy-writable are busy-writable registers.
- Optionally Shadowed/Busy-Writable registers: All registers/fields listed below can be set as either shadow registers or busy-writable registers:
 - When [CCDC_CFG\[15\]](#) VDLC is 0, these registers are shadowed.
 - When [CCDC_CFG\[15\]](#) VDLC is 1, these registers are busy-writable.

NOTE: [CCDC_CFG\[15\]](#) VDLC must be set to 1 by software if the CCDc is to be used; therefore, these registers are busy-writable. If [CCDC_CFG\[15\]](#) VDLC remains set to 0 (default), indeterminate results may occur for ANY register access in the CCDc, not just those listed in the following.

- Optionally shadowed or busy-writable registers
 - [CCDC_SYN_MODE\[19\]](#) SDR2RSZ
 - [CCDC_SYN_MODE\[18\]](#) VP2SDR
 - [CCDC_SYN_MODE\[16\]](#) VDHDEN
 - [CCDC_SYN_MODE\[17\]](#) WEN
 - [CCDC_SYN_MODE\[14\]](#) LPF
 - [CCDC_HD_VD_WID](#)
 - [CCDC_PIX_LINES](#)
 - [CCDC_HORZ_INFO](#)
 - [CCDC_VERT_START](#)
 - [CCDC_VERT_LINES](#)
 - [CCDC_CULLING](#)
 - [CCDC_HSIZE_OFF](#)
 - [CCDC_SDOFST](#)
 - [CCDC_CLAMP\[31\]](#) CLAMPEN
 - [CCDC_FMTCFG\[0\]](#) FMTEN
 - [CCDC_LSC_CONFIG](#)
 - [CCDC_LSC_INITIAL](#)
 - [CCDC_LSC_TABLE_BASE](#)
 - [CCDC_LSC_TABLE_OFFSET](#)

6.5.6.5 Camera ISP CCDc Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Because the [CCDC_PCR](#) register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

6.5.6.6 Camera ISP CCDC Operations

6.5.6.6.1 Camera ISP CCDC Image-Sensor Configuration

6.5.6.6.1.1 Camera ISP CCDC Input-Mode Selection

The CCDC module supports two modes: SYNC mode and ITU-R BT.656 mode. Specific settings correspond to each mode.

- SYNC mode:
 - In this mode, the input data can be either raw data or YCbCr data. Setting `CCDC_SYN_MODE.INPMODE = 0` selects raw data, and `CCDC_SYN_MODE[13:12] INPMODE = 1` or `2` selects YCbCr data on 16 or 8 bits. If `CCDC_SYN_MODE[13:12] INPMODE = 0`, the `cam_d` signal width is selected through `CCDC_SYN_MODE[10:8] DATSIZ`: the possible values are 8, 10, 11, and 12 bits.
 - If `CCDC_SYN_MODE[13:12] INPMODE = 1`, the `cam_d` signal width is 8 bits, but the internal CCDC module data path is configured to 16 bits. It is mandatory to enable the 8- to 16-bit bridge by setting `ISP_CTRL[3:2] PAR_BRIDGE = 2` or `3`. The `ISP_CTRL [3:2] PAR_BRIDGE` bit also controls how the 8-bit data is mapped onto the 16-bit data.
 - The value set in `CCDC_SYN_MODE[10:8] DATSIZ` does not matter. The position of the Y component can be set with the `CCDC_CFG[11] Y8POS` bit.
 - If `CCDC_SYN_MODE[13:12] INPMODE = 2`, the `cam_d` signal width is 8 bits. The value set in `CCDC_SYN_MODE[10:8] DATSIZ` does not matter. The position of the Y component can be set with the `CCDC_CFG[11] Y8POS` bit.
 - The internal timing generator must be enabled with `CCDC_SYN_MODE[16] VDHDEN = 1`.
- ITU mode:
 - In this mode, the data follows the protocol set by the ITU-R BT.656 protocol. To select it, set `CCDC_REC656IF[0] R656ON = 1`. When this mode is selected, the values set in `CCDC_SYN_MODE[13:12] INPMODE` and `CCDC_SYN_MODE[10:8] DATSIZ` do not matter.
 - To select the 8-bit or 10-bit protocol, set the `CCDC_CFG[5] BW656` bit field. Data line `cam_d [7:0]` are used for 8-bit YCbCr and `cam_d[9:0]` are used for 10-bit YCbCr.
 - FVH error correction is enabled by setting `CCDC_REC656IF[1] ECCFVH = 1`.
 - The internal timing generator must be enabled with `CCDC_SYN_MODE[16] VDHDEN = 1`.

6.5.6.6.1.2 Camera ISP CCDC Timing Generator and Frame Settings

The polarities of the `cam_hs`, `cam_vs`, and `cam fld` signals are controlled by the `CCDC_SYN_MODE[3] HDPOL`, `CCDC_SYN_MODE[2] VDPOL`, and `CCDC_SYN_MODE[4] FLDPOL` bit fields. The polarities can be positive or negative.

The pixel data is presented on `cam_d` one pixel for every `cam_pclk` rising edge or falling edge. It is controlled with the `ISP_CTRL[4] PAR_CLK_POL` bit.

The `CCDC_SYN_MODE[7] FLDMODE` bit fields set the image-sensor type to progressive or interlaced mode. When the sensor is interlaced, the `CCDC_SYN_MODE[15] FLDSTAT` status bit indicates whether the current frame is odd or even.

The polarity of the `cam_d` signal can also be controlled with the `CCDC_SYN_MODE[6] DATAPOL` bit field. The polarity can be normal mode or ones complement mode.

Furthermore, the directions of the `cam fld` and `cam_hs/cam_vs` signals are controlled by the `CCDC_SYN_MODE[1] FLDOOUT` and `CCDC_SYN_MODE[0] VDHDOUT` bits. If `CCDC_SYN_MODE[0] VDHDOUT` is set as an output, the `CCDC_PIX_LINES` register controls the length of the `cam_hs` and `cam_vs` signals.

If `CCDC_SYN_MODE[0] VDHDOUT = 1`:

- The HS sync pulse width is given by `CCDC_HD_VD_WID[27:16] HDW`. The VS sync pulse width is given by `CCDC_HD_VD_WID [11:0] VDW`.
- The HS period is given by `CCDC_PIX_LINES[31:16] PPLN`. The VS period is given by

CCDC_PIX_LINES[15:0] HLP RF x 2.

Figure 6-115 shows the HS/VS sync pulse output timings.

Figure 6-115. Camera ISP CCDC HS/VS Sync Pulse Output Timings

camisp-117

6.5.6.6.1.3 Camera ISP CCDC Mosaic Filter Settings

The CCDC module supports image sensors with R, G, and B primary color mosaic filters and Ye, Cy, Mg, and G complementary color mosaic filters. The mosaic filter layout pattern is controlled by the [CCDC_COLPTN](#) register. Each bit field in this register controls the color associated to one pixel in a 4x4 region area. The 4x4 area repeats horizontally and vertically.

Figure 6-116 shows configuration examples of the [CCDC_COLPTN](#) register. It is assumed that CP0LPC0 is the first pixel output and CP3LPC3 is the last pixel output during frame readout.

6.5.6.6.2 Camera ISP CCDC Image-Signal Processing

6.5.6.6.2.1 Camera ISP CCDC Digital Clamp

Digital clamp is enabled only if optical black clamping is disabled: `CCDC_CLAMP[31] CLAMPEN = 0`. The digital clamp DC value to be subtracted from the raw image data (`CCDC_SYN_MODE[13:12] INPMOD = 0`) or from the luminance (`CCDC_SYN_MODE[13:12] INPMOD = 0` or `CCDC_REC656IF[0] R656ON = 1`) is set with the `CCDC_DCSUB` register. The DC value can range from 0 to 212-1. The reset value is 0.

6.5.6.6.2.2 Camera ISP CCDC Optical Black Clamping

Optical black clamping is enabled by setting `CCDC_CLAMP[31] CLAMPEN` to 1. When enabled, an average of black-pixel samples is computed over a window. If the height of the window is $2N$, the average value multiplied by a programmable gain factor is subtracted from the raw image data for the following $2N$ lines. Every $2N$ lines, a new average value is computed. For the first $2N$ lines, 0 is subtracted.

The size of the window and horizontal position are controlled by the `CCDC_CLAMP` register. The vertical position of the window is set to line 0 and cannot be modified:

- `CCDC_CLAMP[30:28] OBSLEN` sets the horizontal size of the window (1, 2, 4 or 8 pixels).
- `CCDC_CLAMP[27:25] OBSLN` sets the vertical size of the window ($2N = 1, 2, 4$ or 8 lines).
- `CCDC_CLAMP[24:10] OBST` sets the horizontal start position of the upper-left corner of the window. It is specified from the start of the HS sync pulse in pixel clocks.

The gain factor is set by the `CCDC_CLAMP[4:0] OBGAIN` bit field. Its fixed-point representation is U5Q4; the range is 0 to 1.9375. The gain factor reset value is 1.

If optical-black clamping is disabled, digital clamp is enabled.

6.5.6.6.2.3 Camera ISP CCDC Black Compensation

Black compensation applies an offset to the raw image data. The offset is applied according to the phase and color for each phase. The black compensation offsets are controlled by the `CCDC_BLKCOMP` register. All offsets are coded in S8Q0 representation (two's complement); the range is -128 to +127.

6.5.6.6.2.4 Camera ISP CCDC Faulty-Pixel Correction

Faulty-pixel correction is enabled by setting the `CCDC_FPC[15]` FPCEN bit to 1. Before activating faulty-pixel correction, set the number of faulty pixels to be corrected in a frame with the `CCDC_FPC[14:0]` FPNUM bit field, set the faulty-pixel LUT in memory, and set the `CCDC_FPC_ADDR` register to the LUT address. The address should be aligned to a 64-bit byte boundary; the 6 LSBs are ignored. Reading the register always shows the 6 LSBs as 0.

If the CCDC module cannot fetch the required faulty-pixel entry in time, an error is set in the `CCDC_FPC[16]` FPERR bit. After the bit is set, no more faulty pixels are corrected in the frame. The bit is automatically cleared on the end of the frame and the feature reenabled for the following frame.

6.5.6.6.2.5 Camera ISP CCDC Data Formatter

The data formatter transforms movie mode readout patterns into Bayer readout patterns. It is enabled by setting `CCDC_FMTCFG[0]` FMTEN to 1.

The `CCDC_FMT_HORZ` and `CCDC_FMT_VERT` registers set a clip window at the input of the data reformatter.

The data formatter converts a single line of movie mode sensor into multiple Bayer lines; it is capable of transforming 1 input line into 1, 2, 3, or 4 output lines. The number of lines generated from one input line is set by the `CCDC_FMTCFG[3:2]` LNUM bit field. The following limitations apply:

- The maximum number of pixels that can be supported in an output line if the input line is transformed into 1 output line is 4x1376 (1376 is the limit of the line memory).
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 2 output lines is 2x1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 3 output lines is 1376.
- The maximum number of pixels that can be supported in an output line if the input line is transformed into 4 output lines is 1376.

The data reformatter gets its flexibility from up to 8 different addresses and a program that can contain up to 16 entries each for the odd and even lines. The program length for even fields is set with the `CCDC_FMTCFG[11:8]` PLEN_EVEN bit field. The program length for odd fields is set with the `CCDC_FMTCFG[7:4]` PLEN_ODD bit fields. Each entry refers to one of the 8 addresses and supports autoincrement and autodecrement.

- The 8 addresses are controlled by the `CCDC_FMT_ADDRx` registers (x = 0 to 7).
- The 16 program entries for even lines are controlled by the `CCDC_PRGEVEN0` and `CCDC_PRGEVEN1` registers. The 16 program entries for odd lines are controlled by the `CCDC_PRGODD0` and `CCDC_PRGODD1` registers.

Modulo addressing is used to access the program entries. Even input lines use the even program and odd input lines use the odd program. Each new pixel in a line uses one program entry.

The `CCDC_VP_OUT` register sets the frame size at the output of the video port.

Example 6-2. Conventional readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 6-63](#)) corresponds to a conventional readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

Table 6-63. Camera ISP CCDC Conventional Readout Pattern 1 to 1

Input	Pixels order in input line								
Line [i]	0	1	2	3	[...]	5500	5501	5502	5503
Output	Pixels order in output line								
Line [i]	0	1	2	3	[...]	5500	5501	5502	5503

To obtain this mapping between the input and output pixels, the following settings apply:

- `CCDC_FMTCFG` [3:2] `LNUM` = 0 Converts to 1 line
- `CCDC_FMTCFG` [11:8] `PLEN_EVEN` = 0 1 program entry
- `CCDC_FMTCFG` [7:4] `PLEN_ODD` = 0 1 program entry
- `CCDC_FMT_ADDR_i` [25:24] `LINE` (i = 0) = 0 Init `ADDR0` pointer to 0th line
- `CCDC_FMT_ADDR_i` [12:0] `INIT` (i = 0) = 0 Init `ADDR0` index to 0th pixel
- `CCDC_PRGEVEN0` [3:0] `EVEN0` = 0 Even prog entry 0: `ADDR0++`
- `CCDC_PRGODD0` [3:0] `ODD0` = 0 Odd prog entry 0: `ADDR0++`
- `CCDC_VP_OUT` [3:0] `HORZ_ST` = 0 Horizontal start
- `CCDC_VP_OUT` [16:4] `HORZ_NUM` = 0 Horizontal size

The program for even and odd lines is executed as follows. Because there is only one program entry, this instruction is executed repeatedly.

```
ADDR0= (0, 0)
While not end_of_line
{
Write incoming pixel to ADDR0
ADDR0+=(1,0)
}
```

Example 6-3. Dual readout pattern: 1 input line = 1 output line

The following input-to-output mapping (see [Table 6-64](#)) corresponds to a conventional dual readout pattern. One input line corresponds to 1 output line; the output can be as large as 4x1376 pixels.

Table 6-64. Camera ISP CCDC Dual Readout Pattern 1 to 1

Input	Pixels order in input line									
Line [i]	0	1	2	3	[...]	4092	4093	4094	4095	
Output	Pixels order in output line									
Line [i]	0	2	4	6	[...]	7	5	3	1	

To obtain this mapping between the input and output pixels, the following settings apply:

- `CCDC_FMTCFG` [3:2] `LNUM` = 0 Converts to 1 line
- `CCDC_FMTCFG` [11:8] `PLEN_EVEN` = 1 2 program entry
- `CCDC_FMTCFG` [7:4] `PLEN_ODD` = 1 2 program entry
- `CCDC_FMT_ADDR_i` [25:24] `LINE` (i = 0) = 0 Init `ADDR0` pointer to 0th line
- `CCDC_FMT_ADDR_i` [12:0] `INIT` (i = 0) = 0 Init `ADDR0` index to 0th pixel
- `CCDC_FMT_ADDR_i` [25:24] `LINE` (i = 1) = 0 Init `ADDR1` pointer to 0th line
- `CCDC_FMT_ADDR_i` [12:0] `INIT` (i = 1) = 4095 Init `ADDR1` index to 4095th pixel
- `CCDC_PRGEVEN0` [3:0] `EVEN0` = 0 Even prog entry 0: `ADDR0++`
- `CCDC_PRGEVEN0` [7:4] `EVEN1` = 3 Even prog entry 1: `ADDR1-`
- `CCDC_PRGODD0` [3:0] `ODD0` = 0 Even prog entry 0: `ADDR0++`
- `CCDC_PRGODD0` [7:4] `ODD1` = 3 Even prog entry 1: `ADDR1-`
- `CCDC_VP_OUT` [3:0] `HORZ_ST` = 0 Horizontal start
- `CCDC_VP_OUT` [16:4] `HORZ_NUM` = 0 Horizontal size

```

ADDR0=(0,0)
ADDR1=(4095,0)
While not end_of_line
{
Write incoming pixel to ADDR0
ADDR0+= (1,0)
Write incoming pixel to ADDR1
ADDR1 -=(1,0)
}
    
```

Example 6-4. Dual readout pattern: 1 input line = 3 output line

The following input-to-output mapping (see [Table 6-65](#)) corresponds to a complex pattern. One input line corresponds to 3 output lines; the output can be as large as 1376 pixels.

Table 6-65. Camera ISP CCDC Dual Readout Pattern 1 to 3

Input	Pixels order in input line								
Line [i]	0	1	2	3	4	5	6	7	8
	9	10	11	[...]					
Output	Pixels order in output line								
Line [3i]			0	6	[...]	23	17	11	5
Line [3i + 1]		2	8	14	[...]	15	9	3	
Line [3i + 2]	4	10	16	22	[...]	7	1		

To obtain this mapping between the input and output pixels, the following settings apply:

- [CCDC_FMTCFG](#) [3:2] LNUM = 2 Converts to 3 lines
- [CCDC_FMTCFG](#) [11:8] PLEN_EVEN = 5 6 program entries
- [CCDC_FMTCFG](#) [7:4] PLEN_ODD = 5 6 program entries
- [CCDC_FMT_ADDR_i](#) [25:24] LINE (i = 0) = 0 Init ADDR0 pointer to 0th line
- [CCDC_FMT_ADDR_i](#) [12:0] INIT (i = 0) = 2 Init ADDR0 index to 2nd pixel
- [CCDC_FMT_ADDR_i](#) [25:24] LINE (i = 1) = 2 Init ADDR1 pointer to 2nd line
- [CCDC_FMT_ADDR_i](#) [12:0] INIT (i = 1) = 855 Init ADDR1 index to 855th pixel
- [CCDC_FMT_ADDR_i](#) [25:24] LINE (i = 2) = 1 Init ADDR2 pointer to first line
- [CCDC_FMT_ADDR_i](#) [12:0] INIT (i = 2) = 1 Init ADDR2 index to first pixel
- [CCDC_FMT_ADDR_i](#) [25:24] LINE (i = 3) = 1 Init ADDR3 pointer to first line
- [CCDC_FMT_ADDR_i](#) [12:0] INIT (i = 3) = 856 Init ADDR3 index to 856th pixel
- [CCDC_FMT_ADDR_i](#) [25:24] LINE (i = 4) = 2 Init ADDR4 pointer to second line
- [CCDC_FMT_ADDR_i](#) [12:0] INIT (i = 4) = 0 Init ADDR4 index to 0th pixel
- [CCDC_FMT_ADDR_i](#) [25:24] LINE (i = 5) = 0 Init ADDR5 pointer to 0th line
- [CCDC_FMT_ADDR_i](#) [12:0] INIT (i = 5) = 857 Init ADDR5 index to 857th pixel
- [CCDC_PRGEVEN0](#) [3:0] EVEN0 = 0 Even prog entry 0: ADDR0++
- [CCDC_PRGEVEN0](#) [7:4] EVEN1 = 3 Even prog entry 1: ADDR1- -
- [CCDC_PRGEVEN0](#) [11:8] EVEN2 = 4 Even prog entry 2: ADDR2++
- [CCDC_PRGEVEN0](#) [15:12] EVEN3 = 7 Even prog entry 3: ADDR3- -
- [CCDC_PRGEVEN0](#) [19:16] EVEN4 = 8 Even prog entry 4: ADDR4++
- [CCDC_PRGEVEN0](#) [23:20] EVEN5 = 11 Even prog entry 4: ADDR5- -
- [CCDC_PRGODD0](#) [3:0] ODD0 = 0 Even prog entry 0: ADDR0++
- [CCDC_PRGODD0](#) [7:4] ODD1 = 3 Even prog entry 1: ADDR1- -
- [CCDC_PRGODD0](#) [11:8] ODD2 = 4 Even prog entry 2: ADDR2++

- [CCDC_PRGODD0](#) [15:12] ODD3 = 7 Even prog entry 3: ADDR3- -
- [CCDC_PRGODD0](#) [19:16] ODD4 = 8 Even prog entry 4: ADDR4++
- [CCDC_PRGODD0](#) [23:20] ODD5 = 11 Even prog entry 4: ADDR5- -
- [CCDC_VP_OUT](#) [3:0] HORZ_ST = 2 Horizontal start, excludes first 2 pixels
- [CCDC_VP_OUT](#) [16:4] HORZ_NUM = 854 Horizontal size

ADDR5 -= (1, 0)
}

```

Video Port

The 10-bit video-port output is enabled with [CCDC_FMTCFG](#)[15] VPEN = 1. Because the input data can be up to 12 bits, one must select which 10 bits are selected with [CCDC_FMTCFG](#)[14:12] VPIN.

The output of the video port goes to the Preview module. At the output of the video port, the data rate is resynchronized; the [CCDC_FMTCFG](#)[21:16] VPIF_FRQ bit field selects the video-output data rate as: L3 speed/([CCDC_FMTCFG](#)[21:16]VPIF_FRQ + 2) (from L3 speed/ 2 MHz to L3 speed/8 MHz). If [CCDC_FMTCFG](#)[21:16] VPIF_FRQ frequency is set too low compared to the input pixel clock, overflow can occur.

6.5.6.6.2.6 Camera ISP CCDC Output Formatter

6.5.6.6.2.6.1 Camera ISP CCDC Low-Pass Filter

The low-pass filter is enabled with the [CCDC_SYN_MODE](#)[14] LPF bit. When enabled, two pixels each in the left and right edges of each line are cropped from the output.

6.5.6.6.2.6.2 Camera ISP CCDC A-Law Compression

A-Law compression is enabled by setting [CCDC_ALAW](#) [3] CCDTBL to 1. The A-Law table is fixed, so no setup is required. When the input is wider than 10 bits, the [CCDC_ALAW](#) [2:0] GWDI bit is used to select which 10 bits of the 12 possible bits are selected for compression. See [Table 6-66](#).

Table 6-66. Camera ISP CCDC [CCDC_ALAW](#) [2:0] GWDI

GWDI	Description
4	Bits 11 to 2
5	Bits 10 to 1
6	Bits 9 to 0
Others	Reserved

6.5.6.6.2.6.3 Camera ISP CCDC Culling

Culling performs a horizontal and vertical decimation function. The horizontal and vertical culling patterns are set by the [CCDC_CULLING](#) register.

- The 8-bit [CCDC_CULLING](#)[31:24] CULHEVN and [CCDC_CULLING](#) [23:16] CULHODD bit fields set the horizontal culling pattern for even and odd lines. A 1 means that the pixel is retained; a 0 means that the pixel is skipped. The same number of retained pixels must be set for even and odd lines.
- The 8-bit [CCDC_CULLING](#)[7:0] CULV bit field sets the vertical culling pattern. The LSB represents the top line and the MSB represents the bottom line. A 1 means that the line is retained; a 0 means that the line is skipped.

6.5.6.6.2.6.4 Camera ISP CCDC Data Packing

Pixel data are stored to memory in little-endian format (bytes at lower addresses have lower significance). By default, pixel data are stored in 16-bit words; unused bits are filled with zeros.

If the input data is 8 bits, or if A-Law compression is enabled, the data can be stored in 8-bit words by setting the [CCDC_SYN_MODE](#)[11] PACK8 bit to 1.

If the input data is 12, 11, 10, or 9 bits, and A-Law compression is not enabled, the 8 MSBs are stored to memory.

Figure 6-117 shows data packing and pixel ordering.

Figure 6-117. Camera ISP CCDC Data Packing - Pixel Ordering

	3 1	2 4	1 5	0 7	0 0
12 bits	0	pix 1	0	pix 0	
11 bits	0	pix 1	0	pix 0	
10 bits	0	pix 1	0	pix 0	
9 bits	0	pix 1	0	pix 0	
8 bits	0	pix 1	0	pix 0	
8 bits packed	pix3	pix 2	pix 1	pix 0	

camisp-118

6.5.6.6.2.6.5 Camera ISP CCDC Clipping Window

Before data is stored in memory, a clipping window can be set; only a selected sensor area is stored to memory. Figure 6-118 shows the settings; only the white area is stored to memory.

- The valid-data horizontal start position is controlled with the [CCDC_HORZ_INFO](#)[30:16] SPH bit field. The valid-data vertical start position is controlled with the [CCDC_VERT_START](#) register. If the sensor is interlaced, the vertical start position for even and odd fields can be configured independently with the [CCDC_VERT_START](#) register. If the sensor is progressive, the [CCDC_VERT_START](#)[14:0] SLV1 bit field is ignored.
- The valid-data horizontal size is controlled with the [CCDC_HORZ_INFO](#)[14:0] NPH bit field. The horizontal size must be a multiple of 16 pixels. The valid-data vertical size is controlled with the [CCDC_VERT_LINES](#)[14:0] NLV register.

Figure 6-118. Camera ISP CCDC Clipping Window Before Output to Memory

camisp-119

6.5.6.6.2.6.6 Camera ISP CCDC Output to Memory

The output formatter memory write enable is controlled by the [CCDC_SYN_MODE\[17\] WEN](#) bit. The output of the data reformatter can be written to memory by setting [CCDC_SYN_MODE\[18\] VP2SDR](#) to 1.

The pixel data at the output of the output formatter is written to the address given by the [CCDC_SDR_ADDR](#) register. The address should be aligned on a 32-byte boundary. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0.

A destination pitch can be set with the [CCDC_HSIZE_OFF](#) register. The offset must be a multiple of 32 bytes. The 5 LSBs are ignored. Reading the register always shows the 5 LSBs as 0. It is required for the pixel line length to be a multiple of 32 bytes to be stored in memory without holes.

The [CCDC_SDOFST](#) register controls how the pixels are stored to memory.

Data to be written to memory can be qualified by the external `cam_wen` signal. This feature can be enabled by setting the [CCDC_SYN_MODE\[5\] EXWEN](#) bit. The [CCDC_CFG \[8\] WENLOG](#) bit configures how the `cam_wen` signal is used with the internally generated valid signal.

The data can be swapped on a byte basis with the [CCDC_CFG\[12\] BSWD](#) bit.

If [CCDC_SYN_MODE\[13:12\] INPMOD](#) = 1, the MSB of the 8-bit chroma component can be inverted by setting [CCDC_CFG\[13\] MSBINVI](#) to 1.

6.5.6.7 Camera ISP CCDC Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the CCDC. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- If faulty-pixel correction is enabled, the [CCDC_FPC_ADDR](#) address should be on a 64-byte boundary.
- External WEN cannot be used when the VP2SDR path is enabled.
- If the formatter is enabled, in line-alternating mode, the vertical start and end number should be even.
- The horizontal number for the video port must be = 1376*4.
- If the video port is enabled, [CCDC_VP_OUT\[30:17\]](#) VERT_NUM must be [CCDC_FMT_VERT\[12:0\]](#) FMTLNV.
- The video port must be enabled if the formatter is enabled.
- In YCC input mode:
 - The [CCDC_COLPTN](#) must be set to 0s.
 - The [CCDC_BLKCMP](#) must be set to 0s.
 - Faulty-pixel correction must be disabled.
 - The video port must be disabled.
 - The formatter must be disabled.
 - The VP2SDR must be disabled.
 - The low-pass filter must be disabled.
 - The A-Law must be disabled.
- In RAW input mode, the resizer output path should not be enabled.

6.5.7 Programming the Preview Engine

This section discusses issues related to software control of the preview engine. It lists which registers are required to be programmed in different modes, how to enable and disable the preview engine, and how to check the status of the preview engine; discusses the different register access types; and enumerates programming constraints.

6.5.7.1 Camera ISP Preview Setup/Initialization

This section discusses the configuration of the preview engine required before image processing can begin.

6.5.7.1.1 Camera ISP Preview Reset Behavior

On hardware reset of the camera ISP, all registers in the preview engine are reset to their reset values. However, because the preview engine programmable tables (gamma, noise filter, luminance enhancer, and CFA coefficients) are stored in internal memory, their contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of these tables are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of these tables remain the same as before the reset.

6.5.7.1.2 Camera ISP Preview Register Setup

Before enabling the preview engine, the hardware must be correctly configured through register writes. [Table 6-67](#) identifies the register parameters that must be programmed before enabling the preview engine.

Table 6-67. Camera ISP Preview Engine Required Configuration Parameters

Function	Configuration Required
Function enable/disable	PRV_PCR[5] INVALAW PRV_PCR[7] DRKFCAP PRV_PCR[6] DRKFEN PRV_PCR[21] SCOMP_EN PRV_PCR[8] HMEDEN PRV_PCR[9] NFEN PRV_PCR[10] CFAEN PRV_PCR[26] GAMMA_BYPASS PRV_PCR[15] YNENHEN PRV_PCR[16] SUPEN PRV_PCR[27] DCOREN
IO ports	PRV_PCR[2] SOURCE PRV_PCR[20] SDRPORT PRV_PCR[19] RSZPORT
Input size	PRV_HORZ_INFO PRV_VERT_INFO
Averager	PRV_AVE
White balance	PRV_PCR[14:11] CFAFMT PRV_WB_DGAIN PRV_WBGAIN PRV_WBSEL
Black adjustment	PRV_BLKADJOFF
RGB-to-RGB blending	PRV_RGB_MAT1 to PRV_RGB_MAT5 PRV_RGB_OFF1 to PRV_RGB_OFF2
RGB-to-YCbCr conversion	PRV_CSC0 to PRV_CSC2
Contrast and brightness	PRV_CNT_BRT
YCC output format	PRV_SETUP_YC PRV_PCR[18:17] YCPOS

The [PRV_PCR](#) register contains control bits that enable or disable optional functions and module IO ports. If an optional function or port is enabled, there may be more registers or configuration information required for the preview engine to operate correctly.

[Table 6-68](#) can be read as:

If (**Condition** is TRUE) then

Configuration required parameters must be programmed.

Table 6-68. Camera ISP Preview Engine Conditional Configuration Parameters

Function	Condition	Configuration Required
Read from CCD	PRV_PCR [2] SOURCE = 0x0	PRV_PCR [3] ONESHOT
Read from memory	PRV_PCR [2] SOURCE = 0x1	PRV_PCR [4] WIDTH PRV_RSDR_ADDR PRV_RADR_OFFSET ISP_CTRL [27] SBL_SHARED_RPORTA
Dark frame subtract	PRV_PCR [6] DRKFEN = 0x1	PRV_DSDR_ADDR PRV_DRKF_OFFSET ISP_CTRL [28] SBL_SHARED_RPORTB Dark frame must be in memory

Table 6-68. Camera ISP Preview Engine Conditional Configuration Parameters (continued)

Function	Condition	Configuration Required
Shading correction	PRV_PCR [21] SCOMP_EN = 0x1 PRV_PCR [6] DRKFEN = 0x1	PRV_PCR [24:22] SCOMP_SFT PRV_DSDR_ADDR PRV_DRKF_OFFSET Dark frame must be in memory
Horizontal median filter	PRV_PCR [8] HME DEN = 0x1	PRV_HMED
Noise filter	PRV_PCR [9] NFEN = 0x1	PRV_NF [1:0] SPR Setup Noise Filter Tables
Defect correction	PRV_PCR [27] DCOREN = 0x1	PRV_PCR [28] DCOR_METHOD PRV_CDC_THRx (x = 0 to 3)
CFA interpolation	PRV_PCR [10] CFAEN = 0x1	PRV_CFA Setup CFA Coefficient Table
Gamma correction	PRV_PCR [26] GAMMA_BYPASS = 0x0	Setup Gamma Correction Tables
Luminance enhancement	PRV_PCR [15] YNENHEN = 0x1	Setup Luminance Enhancement Table
Chrominance suppression	PRV_PCR [16] SUPEN = 0x1	PRV_CSUP
Write to memory	PRV_PCR [20] SDRPORT = 0x1	PRV_WSDR_ADDR PRV_WADD_OFFSET

6.5.7.1.3 Camera ISP Preview Table Setup

The three gamma memories, noise filter threshold memory, noise filter strength memory, luminance enhancer memory, and the CFA coefficient memory must be filled in before the operation of the preview engine, if their respective functions are enabled.

Two registers allow memory contents to be read and written:

- The address register is used to select the specific table entry: [PRV_SET_TBL_ADDR](#).
- The data register contains the data to be written to the specified location: [PRV_SET_TBL_DATA](#).

While the data register is 20 bits wide, only the 8 LSB data is used for the gamma, noise filter, and CFA filter tap memories.

The preview engine supports linear increments on reads and writes automatically. The following examples show how the programmer can read/write the memory. If data is read/written, the address pointer is automatically incremented. For random/noncontiguous reads/writes, [PRV_SET_TBL_ADDR](#) register must be modified.

NOTE: The address is not autoincremented when the preview engine is busy and users try to read/write the tables.

Example:

Read/write all the entries of the CFA table (using linear increment):

- WRITE (SET_TBL_ADDR, 0x1400);
- READ (SET_TBL_DATA, 0xvalue1);
- WRITE (SET_TBL_DATA, 0xvalue2);
- READ (SET_TBL_DATA, 0xvalue3);
- Etc. . . .
- READ (SET_TBL_DATA, 0xvalue163F);

Read/write selective entries of the tables (have to program the address separately for each read/write)

- WRITE (SET_TBL_ADDR, 11);
- READ (SET_TBL_DATA, value11);
- WRITE (SET_TBL_ADDR, 564);
- WRITE (SET_TBL_DATA, value564);

6.5.7.2 Camera ISP Preview Enable/Disable Hardware

Setting the [PRV_PCR\[0\] ENABLE](#) bit to 0x1 enables the preview engine. This must be done after all required registers and tables are programmed.

When the input source is the memory, the preview engine always operates in one-shot mode. In other words, after enabling the preview engine, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCDC, the preview engine can be configured to operate in either one-shot mode or continuous mode ([PRV_PCR \[3\] ONESHOT](#)). Processing of the frame is depends on the timing of the CCDC. To ensure that data from the CCDC is not missed, the preview engine must be enabled before the CCDC so that it waits for CCDC data.

NOTE: In one-shot mode, on setting the ENABLE bit, the processing of the frame begins and the ENABLE, ONESHOT, and SOURCE bits are reset to their reset values.

When the preview engine is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

6.5.7.3 Camera ISP Preview Events and Status Checking

The preview engine generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the PRV_DONE_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [PRV_PCR\[1\] BUSY](#) status bit is set when the start of frame occurs (if the [PRV_PCR\[0\] ENABLE](#) bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [PRV_PCR\[1\] BUSY](#) status bit may be polled to determine end-of-frame status.

The [PRV_PCR\[31\] DRK_FAIL](#) status bit is set when dark-frame data fetched from memory arrives late. This bit can be reset by writing a 1 to the bit.

6.5.7.4 Camera ISP Preview Register Accessibility During Frame Processing

There are three types of register access in the preview engine.

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [PRV_PCR](#)
- [PRV_RSDR_ADDR](#)

- [PRV_RADR_OFFSET](#)
- [PRV_DSDR_ADDR](#)
- [PRV_DRKF_OFFSET](#)
- [PRV_WSDR_ADDR](#)
- [PRV_WADD_OFFSET](#)
- Busy-writable registers: These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.
The busy-writable registers are:
 - [PRV_WB_DGAIN](#)
 - [PRV_WBGAIN](#)
- Busy-lock registers:
 - All registers EXCEPT the shadow and busy-writable registers belong to this category. Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
 - After the [PRV_PCR\[1\]](#) BUSY bit is reset to 0, busy-lock registers can be written.
 - The [PRV_SET_TBL_DATA](#) register cannot be read when the preview engine is busy, because this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading preview engine memories.

The ideal procedure for changing the preview engine registers is:

```
IF (PRV\_PCR\[1\] BUSY == 0) OR IF
(EOF interrupt occurs)
    DISABLE PREVIEW ENGINE
    CHANGE REGISTERS
    ENABLE PREVIEW ENGINE
```

6.5.7.5 Camera ISP Preview Interframe Operations

Between frames, it may be necessary to enable/disable functions or modify memory pointers. Because the [PRV_PCR](#) register and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

6.5.7.6 Camera ISP Preview Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the preview engine. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- A frame can only be read from memory when the SBL read port is affected to the PREVIEW module ([ISP_CTRL\[27\]](#) SBL_SHARED_RPORTA = 0)
- The shading compensation feature can only be used when the SBL read port is affected to the PREVIEW module ([ISP_CTRL\[28\]](#) SBL_SHARED_RPORTB = 0)
- If the memory output port is enabled, the memory output line offset and address should be on 32-byte boundaries.
- The output width must be less than or equal to 4096.
- The output width must be even.
- Input to the horizontal median filter must be even.
- Defect correction can only be used when noise filter is enabled
- Input height must be smaller than CCDC output height.
- The input width of the preview engine must be a multiple of the average count multiplied by the least

common multiple of the odd distance and even distance of the averager.

- $(\text{PRV_HORZ_INFO}[13:0] \text{ EPH} - \text{PRV_HORZ_INFO}[29:16] \text{ SPH} + 1) \text{ MOD } ((1 \text{ PRV_AVE}[1:0] \text{ COUNT}) * \text{LeastCommonMultiple}(\text{PRV_AVE}[5:4] \text{ ODDDIST}+1, \text{PRV_AVE}[3:2] \text{ EVENDIST}+1)) = 0$
- Input width must be at least 4 pixels smaller than CCDC output width:
 - $\text{PRV_HORZ_INFO}[29:16] \text{ SPH}$ at least 2 pixels before last pixel from CCDC
 - $\text{PRV_HORZ_INFO}[13:0] \text{ EPH}$ at least 2 pixels before last pixel from CCDC

6.5.8 Programming the Resizer

This section discusses issues related to software control of the resizer. It lists which registers are required to be programmed in different modes, how to enable and disable the resizer, and how to check the status of the resizer; discusses the different register access types; and enumerates programming constraints.

6.5.8.1 Camera ISP Resizer Setup/Initialization

This section discusses the configuration of the resizer required before image processing can begin.

6.5.8.1.1 Camera ISP Resizer Reset Behavior

On hardware reset of the camera ISP, all registers in the resizer are reset to their reset values.

6.5.8.1.2 Camera ISP Resizer Register Setup

Before enabling the resizer, the hardware must be correctly configured through register writes. [Table 6-69](#) identifies the register parameters that must be programmed before enabling the resizer.

Table 6-69. Camera ISP Resizer Required Configuration Parameters

Function	Configuration Required
Resizer control parameters	RSZ_CNT
IO sizes	RSZ_OUT_SIZE RSZ_IN_START RSZ_IN_SIZE
Memory addresses	RSZ_SDR_INADD RSZ_SDR_INOFF RSZ_SDR_OUTADD RSZ_SDR_OUTOFF
Filter coefficients	RSZ_HFILT10 to RSZ_HFILT3130 RSZ_VFILT10 to RSZ_VFILT3130
Edge enhancement	RSZ_YENH [17:16] ALGO

The edge-enhancement function is optional:

- If it is disabled, the rest of the [RSZ_YENH](#) register does not need to be programmed.
- If it is enabled, the edge-enhancement parameters in [Table 6-70](#) must be programmed so that the edge-enhancement function operates correctly.

[Table 6-70](#) can be read as:

If (**Condition** is TRUE) then

Configuration required parameters must be programmed.

Table 6-70. Camera ISP Resizer Conditional Configuration Parameters

Function	Condition	Configuration Required
Edge enhancement	RSZ_YENH [17:16] ALG0 = 0x1 or 0x2	RSZ_YENH [15:12] GAIN RSZ_YENH [11:8] SLOP RSZ_YENH [7:0] CORE

6.5.8.2 Camera ISP Resizer Enable/Disable Hardware

Setting the [RSZ_PCR](#)[0] ENABLE bit to 0x1 enables the resizer. This must be done after all required registers are programmed.

When the input source is memory, the resizer always operates in one-shot mode. In other words, after enabling the resizer, the [RSZ_PCR](#)[0] ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory.

In this mode, fetching and processing of the frame begin immediately on setting the [RSZ_PCR](#) [0] ENABLE bit.

When the input source is the CCD or preview engine, the resizer can be configured to operate in either one-shot mode, or continuous mode ([RSZ_PCR](#)[2] ONESHOT). Processing of the frame depends on the timing of the CCD/Preview. To ensure that data from the CCD or preview engine is not missed, the resizer must be enabled before to these upstream modules, so it waits for data from the CCD or the preview engine.

When the resizer is started during an ongoing frame the enable is latched at the end of the frame it was written in.

When the resizer is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it was written.

6.5.8.3 Camera ISP Resizer Events and Status Checking

The resizer generates an interrupt event at the end of each frame.

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the [RSZ_DONE_IRQ](#) bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE](#)[x] = 0), the correspondent status ([ISP_IRQ0STATUS](#)[x] = 1) bit is flagged, if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [RSZ_PCR](#)[1] BUSY status bit is set when the start of frame occurs (if the [RSZ_PCR](#)[0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [RSZ_PCR](#)[1] BUSY status bit may be polled to determine end-of-frame status in oneshot mode. [Figure 6-119](#) shows the firmware/hardware interaction. Configuration registers and filter coefficients are programmed in-between or before busy periods, before writing ENABLE to 0x1.

Figure 6-119. Camera ISP Resizer Firmware Interactions for Memory-Input Resizing

NOTE: The [SBL_SDR_REQ_EXP\[19:10\]](#) RSZ_EXP bit field enables the spreading of non-real time read requests over time. It is useful to avoid overflow situations when the resizer module is programmed to work from memory to memory.

6.5.8.4 Camera ISP Resizer Register Accessibility During Frame Processing

There are two types of register access in the resizer.

- **Shadow registers:** These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [RSZ_PCR](#)
- [RSZ_SDR_INADD](#)
- [RSZ_SDR_INOFF](#)
- [RSZ_SDR_OUTADD](#)
- [RSZ_SDR_OUTOFF](#)

- **Busy-lock registers**
 - All registers EXCEPT the shadowed registers belong to this category.
 - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
 - After the [RSZ_PCR\[1\]](#) BUSY bit is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the resizer registers is:

```
IF (RSZ\_PCR\[1\] BUSY == 0) OR IF
(EOF interrupt occurs)
  DISABLE RESIZER
  CHANGE REGISTERS
  ENABLE RESIZER
```

6.5.8.5 Camera ISP Resizer Inter-Frame Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Because the [RSZ_PCR\[0\]](#) ENABLE bit and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is get latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

NOTE: The firmware must compute and upload the filter coefficients. If polyphase resampling is used, a different set is required when changing between 4-tap and 7-tap modes, and with different downsampling factors; all upsampling factors can share the same set of coefficients. Do not change any busy-lock registers while the resizer is operating. Specifically, when back-to-back resizes require changes in any busy-lock registers (such as the coefficients, resizing ratios, input and output sizes), users must wait for the first resize to complete. The following section describes some scenarios where this is required.

6.5.8.5.1 Camera ISP Resizer Multiple Passes for Large Resizing Operations

The resizer supports multiple passes of processing for large resizing operations. "Large" has the following meanings:

- Wider output than 4096 pixels: This works only in memory input mode. Input can be partitioned into multiple resizer blocks, and each block is separately resized and stitched together. Having input/output memory line offsets, input starting pixel and starting phase are essential to make this work. The basic idea is to begin subsequent slices at exactly where previous images leave off. The starting phase and pixel registers can be programmed to this exact location.
- Larger than 4x upsampling: Resizing can be applied in multiple passes. For example, 10x upsampling can be realized by first a 4x upsampling, then a 2.5x upsampling. The first pass can be performed on-the-fly with the preview engine. The second pass can be performed only with input from memory, and for 10x digital zoom; there is time outside the active picture region to perform the second pass.
- Larger than 4:1 downsampling: Although it is rarely necessary to generate a very small image from a large image, this is supported by the hardware. For example, 10x downsampling can be realized first with 4x downsampling on-the-fly with the preview engine, then 2.5x downsampling in the memory-input path. There may not be much time outside the active data region for the second pass, but since the image is already reduced to 1/16 of its original size, not much time is necessary. Typically, sensor or video input has 10 ~ 20 % of usable vertical blanking.

For all these scenarios, the second pass can be configured and initiated from an interrupt service routine triggered by the resizer end-of-frame interrupt: [ISP_IRQ0ENABLE\[24\]](#) RSZ_DONE_IRQ (or [ISP_IRQ1ENABLE](#)).

6.5.8.5.2 Camera ISP Resizer Processing Time Calculation

The time calculated below is the time it takes for all resizes where the input source is memory (second pass when doing a 10x resize in preview mode; in the case of a 10x resize in preview mode, the first pass is hidden behind the time it takes to capture and process the image from the sensor based on cam_pclk and the number of lines resized).

The following equation can be used to determine the processing time of the resizer when the input is from memory and therefore how much time it takes before it can switch back to preview input mode:

$$\text{Time} = [W \times \text{bytes_per_pixel} \times H] / [L3/2] \quad (4)$$

Where:

/ If the input is YUV422 and horizontal downsampling is performed: */*

if ((RSZ_CNT[27] INPTYP ==0) ((RSZ_CNT[9:0] HRSZ + 1) 256))

W = average (input_width, output width); / output width includes extra 4 pixels if edge enhancement is enabled*/*

else

*W = max(input width, output width); /*output width includes extra 4 pixels if edge enhancement is enabled*/*

$$\begin{aligned}
 \text{input_width} &= \text{RSZ_IN_SIZE}[12:0]\text{HORZ} \\
 \text{output_width} &= \text{RSZ_OUT_SIZE}[11:0]\text{HORZ} \\
 \text{input_height} &= \text{RSZ_IN_SIZE}[28:16]\text{VERT} \\
 \text{bytes_per_pixel} &= \begin{cases} 1, & \text{when } \text{RSZ_CNT}[27]\text{INPTYP} = 1 \text{ (color separate)} \\ 2, & \text{when } \text{RSZ_CNT}[27]\text{INPTYP} = 0 \text{ (YUV422)} \end{cases}
 \end{aligned}$$

camisp-E097

This time is the baseline steady state calculation of the hardware and does not include the time it takes for the hardware to fetch the first input and fill the Video processing hardware. It also does not include the time spent from the last output from the resizer to get back to memory when the resizer interrupt occurs.

However, these beginning and ending times are relatively negligible.

Depending on real-time constraints, this processing time may be much faster than is required. (data fetches can be delayed from memory to free more bandwidth for use by other system peripherals; see [Section 6.5.11.5.2, Input from Memory](#).)

6.5.8.6 Camera ISP Resizer Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the resizer. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- Vertical and horizontal resize ratio values must be within the following range: [64..1024].
- Output width:
 - Must be within the maximum limit:
 - width 4096 (if vertical resize value is in range: $(\text{RSZ_CNT}[19:10] \text{ VRSZ} + 1) = [64..512]$)
 - width 2048 (if vertical resize value is in range: $(\text{RSZ_CNT}[19:10] \text{ VRSZ} + 1) = [513..1024]$)
 - Must be even
 - Must be a multiple of 16 bytes (for vertical upsizing)
- When input is from preview engine/CCDC:
 - The input height and width must be = the output of the preview engine/CCDC.
 - The input address and offset must be zero.
 - The input cannot be color-separated data.
- If the source is memory:
 - The vertical start pixel must be zero.
 - The horizontal start pixel must be within the range: 0:15 for color interleaved, 0:31 for color separate data.
 - The memory output line offset and address must be on 32-byte boundaries.
- Input height and width MUST adhere to the equations in [Table 6-71](#).

Table 6-71. Camera ISP Resizer How to Set Input Height and Width

	8-phase, 4-tap mode	4-phase, 7-tap mode
RSZ_IN_SIZE [12:0] HORZ	$(32 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 16) * 8 + 7$	$(64 * \text{sph} + (\text{ow} - 1) * \text{hrs} + 32) * 8 + 7$
RSZ_IN_SIZE [28:16] VERT	$(32 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 16) * 8 + 4$	$(64 * \text{spv} + (\text{oh} - 1) * \text{vrs} + 32) * 8 + 7$

Where:

- sph = Start phase horizontal ([RSZ_CNT\[22:20\]](#) HSTPH)
- spv = Start phase vertical ([RSZ_CNT\[25:23\]](#) VSTPH)
- ow = Output width ([RSZ_OUT_SIZE\[11:0\]](#) HORZ + extra)
- oh = Output height ([RSZ_OUT_SIZE\[27:16\]](#) VERT)
- hrsz = Horizontal resize value ([RSZ_CNT\[9:0\]](#) HRSZ + 1)
- vrsz = Vertical resize value ([RSZ_CNT\[19:10\]](#) VRSZ + 1)
- extra = 0 when [RSZ_YENH\[17:16\]](#) ALGO = 0 (edge enhancement disabled)
- extra = 4 when [RSZ_YENH\[17:16\]](#) ALGO != 0 (edge enhancement enabled)

NOTE: Normally, (for example, for a QVGA display or encoded PAL video), the output size, not the input size, matters. The image provided by preview/CCDC/memory must have an adequate output size: at least [RSZ_IN_SIZE\[12:0\]](#) HORZ x [RSZ_IN_SIZE\[28:16\]](#) VERT. If the image is bigger, the resizer can crop extra pixels.

The phase is usually computed to keep the center of the image at the same location. This permits a natural-looking continuous digital zoom.

For this reason, [Table 6-71](#) explains how to compute [RSZ_IN_SIZE\[12:0\]](#) HORZ , [RSZ_IN_SIZE\[28:16\]](#) VERT, not how to compute the output size.

6.5.9 Programming the H3A

This section discusses issues related to software control of the H3A module. It lists which registers are required to be programmed in different modes, how to enable and disable the H3A, and how to check the status of the H3A. It also discusses the different register access types and enumerates programming constraints.

6.5.9.1 Camera ISP H3A Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

6.5.9.1.1 Camera ISP H3A Reset Behavior

On hardware reset of the camera ISP, all registers in the H3A are reset (set to their reset values).

6.5.9.1.2 Camera ISP H3A Register Setup

For register configuration, the AF engine and the AEW engine of the H3A can be independently be configured. Because there are separate enable bits for each engine, so this section discusses the AF engine and the AEW engine separately.

6.5.9.1.2.1 Camera ISP H3A AF Engine

Before enabling the AF engine, the hardware must be correctly configured through register writes. [Table 6-72](#) identifies the register parameters that must be programmed before enabling the AF engine of the H3A.

Table 6-72. Camera ISP H3A AF Engine Required Configuration Parameters

Function	Configuration Required
AF optional preprocessing	H3A_PCR[2] AF_MED_EN H3A_PCR[1] AF_ALAW_EN
AF mode configuration	H3A_PCR[13:11] RGBPOS H3A_PCR[14] FVMODE

Table 6-72. Camera ISP H3A AF Engine Required Configuration Parameters (continued)

Function	Configuration Required
Paxel start and size information	H3A_AFPAX1
	H3A_AFPAX2
	H3A_AFPAXSTART
	H3A_AFIIRSH
Memory address	H3A_AFBUFST
Filter coefficients	H3A_AFCOE010 to H3A_AFCOE1010

The horizontal median filter function is optional.

If it is disabled, the [H3A_PCR\[10:3\] MED_TH](#) does not need to be programmed.

However, if it is enabled, the [H3A_PCR\[10:3\] MED_TH](#) parameter must be programmed so that the horizontal median filter function operates correctly.

[Table 6-73](#) can be read as:

If (**Condition** is TRUE) then

Configuration required parameters must be programmed

Table 6-73. Camera ISP H3A AF Engine Conditional Configuration Parameters

Function	Condition	Configuration Required
Horizontal median filter	H3A_PCR[2] AF_MED_EN	H3A_PCR[10:3] MED_TH

6.5.9.1.2.2 Camera ISP H3A AEW Engine

Before enabling the AEW engine, the hardware must be correctly configured through register writes.

[Table 6-74](#) identifies the register parameters that must be programmed before enabling the AEW engine of the H3A.

Table 6-74. Camera ISP H3A AEW Engine Required Configuration Parameters

Function	Configuration Required
AEW optional preprocessing	H3A_PCR[17] AEW_ALAW_EN
Saturation limit	H3A_PCR[31:22] AVE2LMT
Window start and size information	H3A_AEWWIN1
	H3A_AEWINSTART
	H3A_AEWINBLK
	H3A_AEWSUBWIN
Memory address	H3A_AEWBUFST

6.5.9.2 Camera ISP H3A Enable/Disable Hardware

Setting the [H3A_PCR\[0\] AF_EN](#) bit enables the AF engine, and the [H3A_PCR\[16\] AEW_EN](#) bit enables the AEW engine. This should be done after all required registers are programmed.

The H3A always operates in continuous mode. Because the input to the H3A module is the video-port interface of the CCDIC, processing of the frame depends on the timing signals from the CCDIC. To ensure that data from the CCDIC is not missed, the H3A should be enabled before the CCDIC so that it waits for CCDIC data.

The AF engine or the AEW engine can be disabled by clearing the [H3A_PCR\[0\] AF_EN](#) or [H3A_PCR \[16\] AEW_EN](#) bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

6.5.9.3 Camera ISP H3A Event and Status Checking

Both the AF engine and the AEW engine generate an interrupt at the end of processing each frame. These interrupt events can be sent to CAM_IRQ0 or CAM_IRQ1 by setting the H3A_AWB_DONE_IRQ or H3A_AF_DONE_IRQ bits in the [ISP_IRQ0ENABLE](#) enable register (or [ISP_IRQ1ENABLE](#)).

The status of these interrupts can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the corresponding bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

6.5.9.4 Camera ISP H3A Register Accessibility During Frame Processing

There are two types of register access in the H3A module:

- Shadow registers: These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- [H3A_PCR](#)
- [H3A_AFBUFST](#)
- [H3A_AEWBUFST](#)

- Busy-lock registers:
 - All registers EXCEPT the shadowed registers belong to this category.
 - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective, but allowed writes from software perspective).
 - After the busy bit in the PCR register is reset to 0, the busy-lock registers can be written ([H3A_PCR \[15\] BUSYAF](#) for AF registers and [H3A_PCR \[18\] BUSYAEAWB](#) for AE/AWB registers).

The ideal procedure for changing the H3A registers is:

```
IF (H3A\_PCR \[15\] BUSYAF == 0 OR H3A\_PCR \[18\] BUSYAEAWB == 0) OR IF (EOF interrupt occurs)
  DISABLE AF or AE/AWB
  CHANGE REGISTERS AF or AE/AWB
  ENABLE AF or AE/AWB
```

6.5.9.5 Camera ISP H3A Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Since the [H3A_PCR](#) and memory pointer registers are shadowed, these modifications can occur any time before the end of the frame, and the data is latched in for the next frame. The MPU subsystem can perform these changes on receiving an interrupt.

6.5.9.6 Camera ISP H3A Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The output addresses must be on 64-byte boundaries.
 - AF Engine:
- The pixel horizontal start value must be greater than or equal to the IIR horizontal start position.

- The width and height of the paxels must be even numbers.
- The minimum width of the autofocus paxel must be 16 pixels.
- Paxels cannot overlap the last pixel in a line.
- Paxels must be adjacent to one another.

AEW Engine:

- The width and height of the windows must be even numbers.
- Subsampling windows can only start on even numbers.
- The minimum width of the AE/AWB windows is 6 pixels.

6.5.10 Programming the Histogram

This section discusses issues related to software control of the histogram module. It lists which registers are required to be programmed in different modes, how to enable and disable the histogram, and how to check the status of the histogram; discusses the different register access types; and enumerates programming constraints.

6.5.10.1 Camera ISP Histogram Setup/Initialization

This section discusses the configuration of the histogram required before image processing can begin.

6.5.10.1.1 Camera ISP Histogram Reset Behavior

On hardware reset of the camera ISP, all registers in the histogram are reset to their reset values. However, since the histogram output memory is stored in internal memory, its contents do not have reset values. If the reset is a chip-level power-on reset (reset after power is applied), the contents of this memory are unknown. If the reset is a camera ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

6.5.10.1.2 Camera ISP Histogram Reset of Histogram Output Memory

Clear the output memory before enabling the histogram. This can be done two ways:

- Writing zeros to the memory through software
- If the [HIST_CNT](#) [7] CLR bit is set, reading the memory causes it to be reset after the read.

Reads and writes to the output memory are blocked when the [HIST_PCR](#) [1] BUSY bit is 1.

6.5.10.1.3 Camera ISP Histogram Register Setup

Before enabling the histogram module, the hardware must be correctly configured through register writes. [Table 6-75](#) identifies the register parameters that must be programmed before enabling the histogram.

Table 6-75. Camera ISP Histogram Required Configuration Parameters

Function	Configuration Required
Histogram Control Bits	HIST_CNT [3] SOURCE HIST_CNT [6] CFA HIST_CNT [5:4] BINS HIST_CNT [2:0] SHIFT HIST_CNT [7] CLR
White Balance Gain	HIST_WB_GAIN
Region n Size and position (n = 0)	HIST_Rn_HORZ HIST_Rn_VERT

Table 6-76 can be read as:

If (**Condition** is TRUE) then

Configuration required parameters should be programmed

Table 6-76. Camera ISP Histogram Conditional Configuration Parameters

Function	Condition	Configuration Required
Input from memory	HIST_CNT [3] SOURCE = 0x1	HIST_CNT [8] DATSIZ HIST_RADD HIST_RADD_OFF HIST_H_V_INFO
Less than 256 bins	HIST_CNT [5:4] BINS 3	HIST_Rn_HORZ (n = 1) HIST_Rn_VERT (n = 1)
Less than 128 bins	HIST_CNT [5:4] BINS 2	HIST_Rn_HORZ (n = 2) HIST_Rn_VERT (n = 2) HIST_Rn_HORZ (n = 3) HIST_Rn_VERT (n = 3)

6.5.10.2 Camera ISP Histogram Enable/Disable Hardware

Setting the [HIST_PCR](#) [0] ENABLE bit enables the histogram module. This must be done after all required registers are programmed and the output memory has been cleared.

When the input source is the memory, the histogram module always operates in one-shot mode. In other words, after enabling the histogram, the ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begin immediately on setting the ENABLE bit.

When the input source is the CCD, the histogram always operates in continuous mode. Processing of the frame depends on the timing of the CCD. To ensure that data from the CCD is not missed, the histogram must be enabled before CCD so it waits for CCD data.

When the histogram is in continuous mode, it can be disabled by clearing the ENABLE bit during the processing of the last frame. The disable is latched in at the end of the frame in which it is written.

6.5.10.3 Camera ISP Histogram Event and Status Checking

The histogram generates an interrupt at the end of each frame.

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written to the HIST_DONE_IRQ bit.

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE](#)[x] = 0), the corresponding status ([ISP_IRQ0STATUS](#) [x] = 1) bit is flagged if the corresponding event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The [HIST_PCR](#) [1] BUSY status bit is set when the start of frame occurs (if the [HIST_PCR](#) [0] ENABLE bit is 1 at that time). It is automatically reset to 0 at the end of a frame. The [HIST_PCR](#) [1] BUSY status bit may be polled to determine the end-of-frame status.

6.5.10.4 Camera ISP Histogram Register Accessibility During Frame Processing

There are two types of register access in the histogram module.

- **Shadow registers:** These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads return the most recent write, even though the settings are not used until the next start of frame.

The shadowed registers are:

- HIST_PCR
- HIST_RADD
- HIST_RADD_OFF
- Busy-lock registers
 - All registers EXCEPT the shadowed registers belong to this category.
 - Busy-lock registers cannot be written when the module is busy. Writes are allowed, but no change occurs in the registers (blocked writes from hardware perspective; allowed write from software perspective).
 - After the HIST_PCR [1] BUSY bit is reset to 0, the busy-lock registers can be written.
 - The HIST_DATA register cannot be read when the histogram is busy, because since this register is mapped to memories internally. Such reads return indeterminate data. Byte enables are not implemented for reading the histogram memory.

The ideal procedure for changing the histogram registers is:

```
IF (HIST_PCR [1] BUSY == 0) OR IF (EOF interrupt occurs)
  DISABLE HISTOGRAM
  CHANGE REGISTERS
  ENABLE HISTOGRAM
```

6.5.10.5 Camera ISP Histogram Interframe Operations

Between frames read from memory, it may be necessary to modify the input memory pointers before processing the next frame. Since the H3A_PCR and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The MPU Subsystem can perform these changes on receiving an interrupt.

If continuous frames are processed without clearing the histogram output memory, the bin counters contain the counts of however many images are processed since they were last cleared. To read the bin counters for each frame, the bin counters must be read after each frame is completed, but before the next frame begins (since the counters cannot be read while the HIST_PCR [1] BUSY bit is 1).

If the input source is memory (one-shot mode), the HIST_PCR [0] ENABLE bit must be set once for the frame, and after the frame is completed, the bin counters can be read/cleared before enabling the next frame.

When the input source is the video-port interface of the CCDIC (continuous mode), the HIST_PCR [0] ENABLE bit must be set to enable processing of the frame, and cleared after the frame processing begins (the disable is latched in at the end of the frame). This procedure allows only one frame to be processed. After the frame is completed, the bin counters can be read/cleared before enabling the histogram for the next frame.

6.5.10.6 Camera ISP Histogram Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the histogram. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The input address and line offset must be on 32-byte boundaries.
- A region dimension of 1 (horizontal or vertical or both) is not allowed.

6.5.11 Programming the Central-Resource SBL

This section discusses issues related to the software control of the central-resource SBL. It lists which registers are required to be programmed in different modes, describes how to check the status of the central resource SBL overflow bits, and enumerates programming constraints.

The central-resource SBL controls data interactions between the camera ISP modules and the interface to memory. A small number of registers configure maximum data-read bandwidth in memory-to-memory operations.

6.5.11.1 Camera ISP Central-Resource SBL Setup/Initialization

This section discusses the configuration of the central-resource SBL required before image processing can begin.

6.5.11.1.1 Camera ISP Central-Resource SBL Reset Behavior

On hardware reset of the camera ISP, all registers in the SBL are reset to their reset values.

6.5.11.1.2 Camera ISP Central-Resource SBL Register Setup

Before enabling any of the camera ISP modules, the hardware must be correctly configured through register writes to the camera ISP registers. If the preview engine, resizer, or the histogram is reading from memory, the [SBL_SDR_REQ_EXP](#) register must be programmed. The values programmed in each of the three fields (PRV_EXP, RSZ_EXP, HIST_EXP) determines the number of clock cycles required to allow two consecutive read requests from the module.

6.5.11.2 Camera ISP Central-Resource SBL Enable/Disable Hardware

The central-resource SBL functionality is always enabled, unless the PRCM idles the clocks to the camera ISP.

6.5.11.3 Camera ISP Central-Resource SBL Event and Status Checking

The SBL generates one interrupt for the write buffer overflow events listed below. Software must check which overflow event has raised the interrupt request, by reading the [SBL_PCR](#) register.

See [Table 6-77](#).

Table 6-77. Camera ISP Central-Resource SBL Write-Buffer Overflow Events

Bit	Event Description
SBL_PCR [26] CSI1_CCP2B_CSI2C_WBL_OVF	CSI1/ CCP2B or CSI2C write-buffer memory overflow
SBL_PCR [25] CSI2A_WBL_OVF	CSI2A write-buffer memory overflow
SBL_PCR [24] CCDCPRV_2_RSZ_OVF	CCDC/PREVIEW to RESIZER input overflow This bit is set if the RESIZER input source is sent to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of 4x is required per frame. Therefore, the RESIZER must operate in two passes. In the first pass, the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should start only after the second pass on the previous frame is complete. This bit indicates the failure status.
SBL_PCR [23] CCDC_WBL_OVF	CCDC write-buffer memory overflow
SBL_PCR [22] PRV_WBL_OVF	PREVIEW write-buffer memory overflow
SBL_PCR [21] RSZ1_WBL_OVF	RESIZER line 1 write-buffer memory overflow
SBL_PCR [20] RSZ2_WBL_OVF	RESIZER line 2 write-buffer memory overflow
SBL_PCR [19] RSZ3_WBL_OVF	RESIZER line 3 write-buffer memory overflow
SBL_PCR [18] RSZ4_WBL_OVF	RESIZER line 4 write-buffer memory overflow
SBL_PCR [17] H3A_AF_WBL_OVF	H3A AF write-buffer memory overflow
SBL_PCR [16] H3A_AEAWB_WBL_OVF	H3A AE/AWB write-buffer memory overflow

The status of this interrupt can be checked by reading the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#)). When the read of the register [ISP_IRQ0STATUS](#) occurs (or [ISP_IRQ1STATUS](#)), the register is not automatically reset. To reset the interrupt, a 1 must be written:

- To the corresponding bit(s) in the [SBL_PCR](#) registers
- To the OVF_IRQ bit in the [ISP_IRQ0STATUS](#) register (or [ISP_IRQ1STATUS](#))

Each event that generates an interrupt can be individually mapped to ARM or DSP using the [ISP_IRQ0ENABLE](#) register (or [ISP_IRQ1ENABLE](#)). When a particular event is not enabled (for example [ISP_IRQ0ENABLE\[x\] = 0](#)), the correspondent status ([ISP_IRQ0STATUS \[x\] = 1](#)) bit is flagged if the correspondent event occurs. This has no effect on the interrupt line, but can be used by software to poll the status.

The SBL flags no read buffer logic underflow events. These are signaled by the reading module. [Table 6-78](#) lists the read port and corresponding events if they exist.

Table 6-78. Camera ISP Central-Resource SBL Read-Buffer Underflow Events

Read port	Description
CCDC faulty pixel	When faulty-pixel correction is used, the pixel frequency is imposed by the camera clock. This imposes read-time constraints to the faulty-pixel table read. When the table read was too slow, the CCDC_FPC [16] FPERR bit is set to 1 and no more faulty pixels are processed for that frame. This error generates an interrupt that can be mapped to DSP or ARM by setting the CCDC_ERR_IRQ bit in the ISP_IRQ0ENABLE register (or ISP_IRQ1ENABLE). To clear this interrupt, clear the CCDC_FPC [16] FPERR bit before clearing the ISP_IRQ0STATUS [11] CCDC_ERR_IRQ bit (or ISP_IRQ1STATUS).
CCDC lens-shading compensation	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, then the CCDC_LSC_PREFETCH_ERROR event is triggered and an interrupt generated.
Preview dark frame	There must be adequate memory bandwidth if this feature is enabled. If the data fetched from memory arrives late, the PRV_PCR [31] DRK_FAIL status bit is set to indicate a fail. No interrupt is generated by this event.
Preview image from memory	No error can occur on this port because the preview module stops processing when no image data is ready.
Resizer image from memory	No error can occur on this port because the resizer module stops processing when no image data is ready.
Histogram image from memory	No error can occur on this port because the histogram module stops processing when no image data is ready.
CSI1/CCP2B image from memory	No error can occur on this port because the CSI1/CCP2B module stops processing when no image data is ready.

6.5.11.4 Camera ISP Central-Resource SBL Register Accessibility During Frame Processing

The central resource SBL registers are all busy-writable registers.

- Busy-writable registers
 - These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantaneously.

6.5.11.5 Camera ISP Central-Resource SBL Camera ISP Bandwidth Adjustments

For memory-to-memory operation, the camera ISP processes data at the highest possible data rate. If this processing returns results long before real-time deadlines, the performance of other peripherals in the system may be negatively affected. The camera ISP offers two kinds of adjustments that can slow down data processing in this situation. One can be made when the sensor input to the CCDC is the input source, and the other can be made when the memory is the source of the input image.

6.5.11.5.1 Camera ISP Central-Resource SBL Input From CCDC Video-Port Interface

The video-port interface delivers data at a rate independent of the pixel clock when the data reformatter is enabled. By default, this rate is set to 100 MHz, which is fast enough to support a parallel interface clock of 90 MHz or a CSI/CCP2B /CSI2 clock of 100 MHz. When the pixel clock is at a lower frequency, it is unnecessary for the video-port interface to operate at such a high frequency. The [CCDC_FMTCFG \[21:16\]](#) VPIF_FRQ field of the CCDC can be programmed to reduce the rate at which the video port delivers new data to the other modules (Preview, H3A, and histogram). In effect, this register indirectly controls the output bandwidth of the preview engine, resizer, and H3A. Depending on the input sensor clock, Users can set this field appropriately and balance the bandwidth requirements to memory. [Figure 6-120](#) demonstrates how this register can expand processing time per line for lower PCLK frequencies.

Figure 6-120. Camera ISP Central-Resource SBL Video-Port Interface Bandwidth Balancing

camisp-091

6.5.11.5.2 Camera ISP Central-Resource SBL Input From Memory

When the input image is from memory, data is fetched from memory and processed at a steady state rate of 200 MB/sec. Depending on the image size and real-time deadline for each frame, this may be much faster than necessary. Such activity can also starve other processes in the system. Internally, when a CAMERA ISP module receives input from memory, the CAMERA ISP makes a read request to the L3 interconnect whenever there is available memory in its internal buffers.

The [SBL_SDR_REQ_EXP](#) register can be programmed to control the rate at which a camera ISP module (Preview, resizer, or histogram) reads the input frame from memory. This indirectly controls the output bandwidth of the preview engine and resizer. Depending on the size of the images and the real-time deadlines, users can set this field appropriately and balance the bandwidth requirements to memory.

The minimum number of cycles (L3) in between read requests used to program the [SBL_SDR_REQ_EXP](#) register can be determined based on the frame size and real-time requirement using the following equation:

$$\text{Number of cycles/request} = (\text{DMA cycles/frame}) / (\text{DMA read requests/frame})$$

In the previous equation, (DMA cycles/frame) is based on a real-time requirement. For example, if the real-time requirement is a frame rate of 1/30 sec and the L3 clock equals the ISP clock, this can be calculated as:

$$(\text{DMA cycles/frame}) = \text{L3 clock} * \text{frame rate} = \text{ISP clock} * 1/30 = 5.53\text{M cycles}$$

The (DMA read requests/frame) is based on the frame size and the alignment in memory. Assuming a VGA (640 x 480) frame size and optimal alignment conditions:

$$(\text{DMA read requests/frame}) = \text{Transfers per line} * \text{number of lines} = 640 \text{ pix/line} * 2 \text{ bytes/pix} / 256 \text{ bytes/xfer} * 480 \text{ lines} = 2400 \text{ requests/frame}$$

In this example, the final equation can now be solved:

$$\text{Number of cycles/request} = 5.53\text{M cycles} / 2400 \text{ requests} = 2306 \text{ cycles/request}$$

[Figure 6-121](#) demonstrates how this register can expand processing time for lower real-time requirements.

Figure 6-121. Camera ISP Central-Resource SBL Memory Read Bandwidth Balancing

The maximum values that can be written to the [SBL_SDR_REQ_EXP](#) register for the different read requestors is 1023. For the histogram and preview engine, this should be sufficient for the typical size of RAW data frames. However, because the resizer can read a variety of video frame sizes, the field for the resizer is internally multiplied by 32. Therefore, for this example, the [SBL_SDR_REQ_EXP\[19:10\]](#) RSZ_EXP bit field can be programmed to $\text{FLOOR}(2306/32) = 72$.

The previous equations provide an estimate or a starting point for programming this register. Depending on the system loads and available bandwidth, it may be necessary to reduce this number to compensate for a heavily loaded system.

NOTE: The granularity for the resizer, HIST, and preview is 32.

6.5.12 Programming the Circular Buffer

6.5.12.1 Camera ISP CBUFF Setup/Initialization

This section discusses the configuration of the circular buffer required before address translation can begin.

6.5.12.2 Camera ISP CBUFF Reset Behavior

Upon hardware reset of the circular buffer, all of the registers in the circular buffer are reset to their reset values.

6.5.12.3 Camera ISP CBUFF Register Setup

All registers of the circular buffer to be used (CBUFFx, x=0 or 1) have to be initialized for correct operation.

The [CBUFFx_START](#) and [CBUFFx_END](#) register define the virtual address range managed by the circular buffer. It usually corresponds to the address region where one image frame is written by the camera ISP.

The window count and size are set through the [CBUFFx_CTRL](#) [9:8] WCOUNT and [CBUFFx_WINDOWSIZE](#) registers. The window size usually depends on the utilization of the buffer. 8 or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency related overflow protection.

When the camera ISP accesses data in an incremental addressing scheme, the next window is never used. In this case the overflow event generation, when the processor window falls into the "next window", can be disabled by setting the [CBUFFx_CTRL](#) [3] ALLOW_NW_EQ_CPUW flag.

When the 2D addressing capability is not used the [CBUFFx_THRESHOLD](#) register is set to the window size. Otherwise it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to 8 lines by 4096 pixel but the camera ISP only send lines of 2560 pixels the [CBUFFx_WINDOWSIZE](#)=8*4096 and [CBUFFx_THRESHOLD](#)=8*2560.

When the register setup is completed the module is enabled using the [CBUFFx_CTRL](#) [0] EN bit.

It can be disabled by clearing the [CBUFFx_CTRL](#) [0] EN bit. This must only be done when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the circular buffer are reset when it is disabled. Pending interrupts are not affected.

6.5.12.4 Camera ISP CBUFF Event and status Checking

6.5.12.4.1 Camera ISP CBUFF Interrupts

All events generated by the circular buffer are mapped to an unique event at camera ISP level: [CBUFF_IRQ](#),

The CBUFF module event can be mapped to the MPU SS or to the IVA SS.

The [CBUFF_IRQ](#) bit in the [ISP_IRQ0ENABLE](#) [21] [CBUFF_IRQ](#) register control whether the CBUFF module event triggers an interrupt to the MPU SS. The [CBUFF_IRQ](#) bit in the [ISP_IRQ0ENABLE](#) [21] [CBUFF_IRQ](#) register control whether the CBUFF module event triggers an interrupt to the IVA2.2 SS.

When an event has been triggered the [ISP_IRQ0STATUS](#) [21] [CBUFF_IRQ](#) bit is set (or [ISP_IRQ1STATUS](#)). SW must than read the [CBUFF_IRQSTATUS](#) register to know which circular buffer event has triggered the interrupt. SW must clear the event first in the circular buffer module by writing 1 to the proper bit in [CBUFF_IRQSTATUS](#) register and then clear the event at camera ISP level by writing 1 to the [ISP_IRQ0STATUS](#) [21] [CBUFF_IRQ](#) bit (or [ISP_IRQ1STATUS](#)). If another event is pending at circular buffer level, the [CBUFF_IRQ](#) interrupt is triggered again.

6.5.12.4.2 Camera ISP CBUFF Status Checking

The event status can be checked through the [CBUFFx_READY_IRQ](#), [CBUFFx_INVALID_IRQ](#), and [CBUFFx_OVR_IRQ](#) bits in the [CBUFF_IRQSTATUS](#) registers.

In addition to those status bits the circular buffer module provides read only access to the "current window", "next window" and "CPU windows" indexes through the [CBUFFx_STATUS](#) register. The "CPU window" index can for example be used by the processor to compute the address of the physical buffer. Those indexes can also be used to evaluate latency margins.

6.5.12.5 Camera ISP CBUFF Register Accessibility During Frame Processing

All registers are Busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantaneously. However the module behavior is unpredictable when registers are changed during processing.

For correct operation software must follow the following steps:

- Disable all accesses to the virtual space managed by CBUFFx. For example when the circular buffer relocates data provided by the CCD module SW must disable the CCD module and check SBL status registers to make sure there are no more outstanding transactions.
- Disable circular buffer x by clearing the [CBUFFx_CTRL](#) [0] ENABLE bit.
- Change the configuration.
- Re-enable CBUFFx by setting the [CBUFFx_CTRL](#) [0] ENABLE bit.

6.5.12.6 Camera ISP CBUFF Operations

A [CBUFFx_READY_IRQ](#) event is generated each time processor can read data from the circular buffer. Processor can clear the event when it starts processing the data to avoid masking of other events. Processor can keep trace of the location on the data internally or use the circular buffer registers to compute it.

The formula used for CBUFF1 is:

$$\text{ADDR} = \text{CBUFFx_STATUS}[3:0] \text{ CPUW} \times \text{CBUFFx_WINDOWSIZE} + \text{CBUFFx_START} \quad (5)$$

Because of the functionality of the fragment, the formula used for CBUFF0 is:

$$\text{ADDR} - \text{CBUFFx_ADDRy}[\text{CBUFFx_STATUS}[3:0] \text{ CPUW}] \quad (6)$$

When processor is done with processing, it must free the buffer by setting the `CBUFFx_CTRL[2]` DONE bit. Otherwise an overflow event may occur.

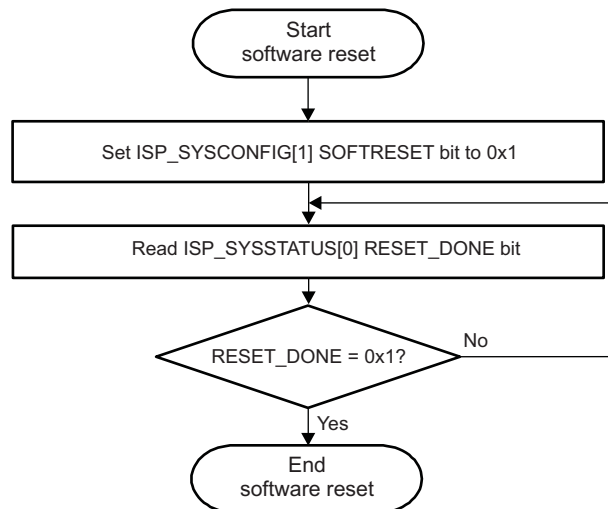

The circular buffer does not keep trace of end of frame events. They must be managed by the processor using the end of frame event of the module that writes into the circular buffer. At the end of the frame there may remain data in the "current write" and "next write" windows. For example, when the window size is set to 8 lines and the image size is 20 lines only 2 window ready events are generated for a linear addressing scheme. The remaining 4 lines can be read after the end of frame event.

No automatic reset of the CBUFF FSM occurs at the end of the camera ISP frame. Software must reset the CBUFF by clearing the `CBUFFx_CTRL[0]` ENABLE bit when the frame has been completely processed. A new frame can only start when `CBUFFx_CTRL [0]` ENABLE has been set.

6.5.13 Programming the Camera ISP Software Reset

The flow chart in [Figure 6-122](#) describes the steps to perform a software reset.

Figure 6-122. Camera ISP Software Reset Sequence

camisp-404

[Table 6-79](#) lists the registers to configure for the camera subsystem software reset step.

Table 6-79. Camera ISP Software Register Settings

Register Name	Address	Value Description
ISP_SYSCONFIG	0x480B C004	Initiate a software reset. The <code>ISP_SYSCONFIG[1]</code> SOFTRESET is automatically reset by hardware.
ISP_SYSSTATUS	0x480B C008	The <code>ISP_SYSSTATUS[0]</code> RESETDONE is set to 1 when the reset sequence is done.

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection is chosen with the ISP_CTRL.SYNC_DTECT bit field. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
30	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
29	OCP_ERR_IRQ	ISP interconnect error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
28	MMU_ERR_IRQ	MMU error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
27:26	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
25	OVF_IRQ	Central Resource SBL overflow This event is triggered when one of the buffer in the central resource SBL overflows. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
23:22	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
21	CBUFF_IRQ	Circular buffer interrupt 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read to slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. Could be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It could be used to minimize buffer underflow risks. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
16	HIST_DONE_IRQ	HIST module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
15	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0
14	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
11	CCDC_ERR_IRQ	CCDC module - faulty pixel correction memory underflow 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
8	CCDC_VD0_IRQ	CCDC module - programmable event 0. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
7	CSIB_LC3_IRQ	CSI1/CCP2B receiver module - event on logical channel 3. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
6	CSIB_LC2_IRQ	CSI1/CCP2B receiver module - event on logical channel 2. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
5	CSIB_LC1_IRQ	CSI1/CCP2B receiver module - event on logical channel 1. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
4	CSIB_LC0_IRQ	CSI1/CCP2B receiver module - event on logical channel 0. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
3	CSIB_LCM_IRQ	CSI1/CCP2B receiver module - event on memory channel. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
2	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
1	CSI2C_IRQ	CSI2C module event. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
0	CSI2A_IRQ	CSI2A module event. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0

Table 6-92. ISP_IRQ1ENABLE

Address Offset	0x0000 0014	Instance	ISP
Physical Address	See Table 6-81		
Description	INTERRUPT ENABLE REGISTER TO DSP. IRQ1 STATUS LINE. The same events are mapped in IRQ0. However, one event shall be mapped to only one target.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_VS_IRQ	RESERVED	OCP_ERR_IRQ	MMU_ERR_IRQ	RESERVED	OVF_IRQ	RSZ_DONE_IRQ	RESERVED	CBUFF_IRQ	PRV_DONE_IRQ	CCDC_LSC_PREFETCH_ERROR	CCDC_LSC_PREFETCH_COMPLETED	CCDC_LSC_DONE	HIST_DONE_IRQ	RESERVED	RESERVED	H3A_AWB_DONE_IRQ	H3A_AF_DONE_IRQ	CCDC_ERR_IRQ	CCDC_VD2_IRQ	CCDC_VD1_IRQ	CCDC_VD0_IRQ	CSIB_LC3_IRQ	CSIB_LC2_IRQ	CSIB_LC1_IRQ	CSIB_LC0_IRQ	CSIB_LCM_IRQ	RESERVED	CSI2C_IRQ	CSI2A_IRQ		

Bits	Field Name	Description	Type	Reset
31	HS_VS_IRQ	HS or VS synchro event This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection is chosen with the ISP_CTRL.SYNC_DTECT bit field.	RW	0
30	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
29	OCP_ERR_IRQ	ISP interconnect error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
28	MMU_ERR_IRQ	MMU error. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
27:26	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
25	OVF_IRQ	Central Resource SBL overflow This event is triggered when one of the buffer in the central resource SBL overflows. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
24	RSZ_DONE_IRQ	RESIZER module - resizer processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
23:22	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
21	CBUFF_IRQ	Circular buffer interrupt 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
20	PRV_DONE_IRQ	PREVIEW module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
19	CCDC_LSC_PREFETCH_ERROR	The prefetch error indicates when the gain table was read to slowly from SDRAM. When this event is pending the module goes into transparent mode (output=input). Normal operation can be resumed at the start of the next frame after 1) clearing this event 2) disabling the LSC module 3) enabling it 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
18	CCDC_LSC_PREFETCH_COMPLETED	Indicates current state of the prefetch buffer. Could be used to start sending the data once the buffer is full to minimize the risk of an underflow. This event is triggered when the buffer contains 3 full paxel rows. It could be used to minimize buffer underflow risks. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
17	CCDC_LSC_DONE	The event is triggered when the internal state of LSC toggles from BUSY to IDLE. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
16	HIST_DONE_IRQ	HIST module - processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
15	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0
14	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
13	H3A_AWB_DONE_IRQ	H3A module - auto exposure and auto white balance processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
12	H3A_AF_DONE_IRQ	H3A module - autofocus processing done event. This event is triggered at the end of the frame when the processing is completed for the current frame. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
11	CCDC_ERR_IRQ	Write 0's for future compatibility. Reads returns 0.	RW	0
10	CCDC_VD2_IRQ	CCDC module - programmable event 2 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
9	CCDC_VD1_IRQ	CCDC module - programmable event 1. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
8	CCDC_VD0_IRQ	CCDC module - programmable event 0. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
7	CSIB_LC3_IRQ	CSI1/CCP2B receiver module - event on logical channel 3. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
6	CSIB_LC2_IRQ	CSI1/CCP2B receiver module - event on logical channel 2. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
5	CSIB_LC1_IRQ	CSI1/CCP2B receiver module - event on logical channel 1. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
4	CSIB_LC0_IRQ	CSI1/CCP2B receiver module - event on logical channel 0. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0

Bits	Field Name	Description	Type	Reset
3	CSIB_LCM_IRQ	CSI1/CCP2B receiver module - event on memory channel. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
2	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
1	CSI2C_IRQ	CSI2C module event. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0
0	CSI2A_IRQ	CSI2A module event. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs.	RW	0

Table 6-96. TCTRL_GRESET_LENGTH

Address Offset	0x0000 0030	
Physical Address	See Table 6-81	Instance ISP
Description	TIMING CONTROL - GLOBAL SHUTTER LENGTH REGISTER This register is used by the TIMING CTRL module to generate the CAM.GRESET signal.	
Type	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								LENGTH																							

Bits	Field Name	Description	Type	Reset
31:24	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x00
23:0	LENGTH	Sets the length of the CAM.GLOBAL_RESET signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.GRESETEN bit is automatically cleared. The possible values are 0 to 2 ²⁴ -1 cycles. The polarity of the CAM.GLOBAL_RESET signal is set by the TCTRL_CTRL.GRESETPOL bit.	RW	0x000000

Table 6-98. TCTRL_PSTRB_REPLAY

Address Offset	0x0000 0034		
Physical Address	See Table 6-81	Instance	ISP
Description	TIMING CONTROL - PRESTROBE REPLAY REGISTER This register is used by the TIMING CTRL module to generate the prestrobe signal.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
COUNTER								DELAY																							

Bits	Field Name	Description	Type	Reset
31:25	COUNTER	Sets the number of PRESTROBE pulses after the original pulse. If this bit is set to 0, the PRESTROBE signal behavior is only controlled by TCTRL_FRAME.STRB , TCTRL_PSTRB_DELAY and TCTRL_PSTRB_LENGTH . If TCTRL_PSTRB_LENGTH =0, there is no replay. This bit is useful when one wants to enable red-eye removal.	RW	0x00
24:0	DELAY	Sets the delay for the PRESTROBE signal re-assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to 2 ²⁵ -1 cycles. If TCTRL_PSTRB_LENGTH =0, there is no replay. This bit field shall not be set to 0 if the COUNTER is set to a value different of 0. This bit is useful when one wants to enable red-eye removal.	RW	0x0000000

26	SBL_SHARED_WPORTC	Controls SBL shared write port C access 0x0: CSI1/CCP2B : CCP2 protocol engine 0x1: CSI2C : CSI2C protocol engine	RW	0
25:24	CBUFF1_BCF_CTRL	Bandwidth control feedback loop configuration register 0x0: Disabled. 0x1: The BCF signal of CBUFF1 stalls the response phase of the CSI1/CCP2B Interconnect read master port. 0x2: The BCF signal of CBUFF1 stalls the request phase of the CSI1/CCP2B Interconnect read master port. 0x3: The BCF signal of CBUFF1 stalls the request and response phase of the CSI1/CCP2B Interconnect read master port.	RW	0x0
23:22	CBUFF0_BCF_CTRL	Bandwidth control feedback loop configuration register 0x0: Disabled. 0x1: The BCF signal of CBUFF0 stalls the response phase of the CSI1/CCP2B Interconnect read master port. 0x2: The BCF signal of CBUFF0 stalls the request phase of the CSI1/CCP2B Interconnect read master port. 0x3: The BCF signal of CBUFF0 stalls the request and response phase of the CSI1/CCP2B Interconnect read master port.	RW	0x0
21	SBL_AUTOIDLE	Sets the SBL autoidle mode 0x0: Disabled 0x1: Enabled	RW	1
20	SBL_WR0_RAM_EN	This bit controls the SBL module WRITE0 RAM used by the RESIZER module. If the RESIZER module is disabled, this bit shall be set to '0' to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0
19	SBL_WR1_RAM_EN	This bit controls the SBL module WRITE1 RAM. If the RESIZER module is the only module enabled to perform memory to memory resize operations, this bit shall be set to '0' to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0

Bits	Field Name	Description	Type	Reset
18	SBL_RD_RAM_EN	This bit controls the SBL module READ RAM. If no read requests are generated, this bit shall be set to '0' to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0
17	PREV_RAM_EN	This bit controls the PREVIEW module RAM. If the PREVIEW module is not used, this bit shall be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0
16	CCDC_RAM_EN	This bit controls the CCDC module RAM. If the CCDC module is not used, the bit shall be set to 0 to save power. 0x0: RAM is disabled 0x1: RAM is enabled	RW	0
15:14	SYNC_DETECT	HS or VS synchronization signal detection It is sometimes necessary to detect the rising or falling edge of the horizontal and vertical synchro signals. When such event is detected, an interrupt will be triggered if ISP_IRQ0ENABLE.HS_VS_IRQ = 1 or ISP_IRQ0ENABLE.HS_VS_IRQ = 1 . 0x0: HS falling edge 0x1: HS rising edge 0x2: VS falling edge 0x3: VS rising edge	RW	0x0
13	RSZ_CLK_EN	RSZ module clock enable. This bit controls the clock distribution to the RSZ module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0
12	PRV_CLK_EN	PRV module clock enable. This bit controls the clock distribution to the PRV module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0
11	HIST_CLK_EN	HIST module clock enable. This bit controls the clock distribution to the HIST module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0
10	H3A_CLK_EN	H3A module clock enable. This bit controls the clock distribution to the H3A module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0
9	CBUFF_AUTOGATING	CBUFF module autogating feature control 0x0: CBUFF autogating feature is disabled. The CBUFF internal clock is free running. 0x1: CBUFF autogating feature is enabled. The CBUFF internal clock is only enabled when it is requested by the CBUFF module.	RW	1

Bits	Field Name	Description	Type	Reset
8	CCDC_CLK_EN	CCDC module clock enable. This bit controls the clock distribution to the CCDC module. 0x0: Disable clock. The module is not active. However, accesses on the module slave port to configure it are still possible. 0x1: Enable clock. The module is fully functional.	RW	0
7:6	SHIFT	Data lane shifter The parallel interface is a 12-bit interface, The video port of CSI1/CCP2B is a 12-bit interface, The video port of CSI2A or CSI2C is a 14-bit interface. The CAMERA ISP has 14 data lanes but the full imaging pipeline only supports 10 bits. There are 2 main utilizations of the data lane shifter 1) Dynamic reduction: For example data from a 12 bit sensor could be converted into 10bit. 2) When a camera module as fewer than 12 data lanes, the ISP requires the pins to be connected on the least significant lanes. An issue occurs when a n-bit camera parallel interface can work in a m-bit mode with mn. The ISP expects the m bits to be on the least significant data lanes whereas it is not correct. The data lane shifter takes place before the CCDC module 0x0: No shift. CAMEXT[13:0] - CAM [13:0] 0x1: Shift by 2. CAMEXT[13:2] - CAM [11:0] 0x2: Shift by 4 CAMEXT[13:4] - CAM [9:0] 0x3: Shift by 6 CAMEXT[13:6] - CAM [7:0]	RW	0x0
5	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0
4	PAR_CLK_POL	This bit sets the pixel clock polarity on the parallel interface. The pixel clock is used for latching the pixel data into the CCDC module. 0x0: Clock not inverted. The data are sampled on the rising edge of the clock. 0x1: Clock inverted. The data are sampled on the falling edge of the clock.	RW	0
3:2	PAR_BRIDGE	This bit field controls the 8 to 16-bit bridge at the input of the CCDC module. 0x0: The bridge is disabled: no conversion. 0x1: Reserved 0x2: The bridge is enabled. The first byte is written to CAM.DATA[7:0], the second byte is written to CAM.DATA[15:8] 0x3: The bridge is enabled. The first byte is written to CAM.DATA[15:8], the second byte is written to CAM.DATA[7:0]	RW	0x0
1:0	PAR_SER_CLK_SEL	Selects the serial or parallel interface as the input to the preview hardware. 0x0: Selects the 12-bit parallel interface as the input to the CCDC module. 0x1: Selects the CSI2A as the input to the CCDC module. 0x2: Selects the CSI1/CCP2B serial interface as the input to the CCDC module. 0x3: Selects the CSI2C as the input to the CCDC module.	RW	0x0

Table 6-102. TCTRL_CTRL

Address Offset	0x0000 0050	Instance	ISP
Physical Address	See Table 6-81		
Description	TIMING CONTROL - CONTROL REGISTER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
GRESETDIR	GRESETPOL	GRESETEN	INSEL	STRBPSTRBPOL	RESERVED	SHUTPOL	STRBEN	PSTRBEN	SHUTEN	RESERVED	DIVC						DIVB			DIVA											

Bits	Field Name	Description	Type	Reset
31	GRESETDIR	Sets the direction of the GLOBAL_RESET signal. 0x0: INPUT. GLOBAL_RESET is an input to the TIMING CONTROL module. GLOBAL_RESET is externally generated. 0x1: OUTPUT. GLOBAL_RESET is an output of the TIMING CONTROL module. GLOBAL_RESET is internally generated. If GRESETEN is set to 1, the internally generated GLOBAL_RESET will trigger the generation of the PRESTROBE, STROBE and SHUTTER signals. The frame counters are ignored.	RW	0

Bits	Field Name	Description	Type	Reset
30	GRESETPOL	Sets the polarity of the global reset signal: CAM.GLOBAL_RESET. It applies whatever the direction of the GLOBAL_RESET signal: input or output. 0x0: active high 0x1: active low	RW	0
29	GRESETEN	Triggers the generation of the CAM.GLOBAL_RESET signal. The signal is asserted immediately. If enabled, the CAM.GLOBAL_RESET signal will be asserted for TCTRL_GRESET_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. The polarity of the GLOBAL_RESET signal is set with TCTRL_CTRL.GRESETPOL . Enabling this bit triggers the generation of the CAM.SHUTTER and CAM.STROBE signals (if previously enabled). The frame counters shall be set to 0 when this bit is set to 1 and GRESETDIR is set a OUTPUT.	RW	0
28:27	INSEL	Sets the mode that will trigger the SHUTTER, PRESTROBE and STROBE signals. 0x0: Video port. The VS sync pulse at the input of the CCDC module is used to count the frames. The source of the VS pulse is selected by the ISP_CTRL [1:0] PAR_SER_CLK_SEL register. 0x1: CSI2A interface. The frame start code (FSC) and frame end code (FEC) sync codes are used to count the frames. 0x2: CSI1/CCP2B or CSI2C interface. The frame start code (FSC) and frame end code (FEC) sync codes are used to count the frames. 0x3: GRESET. The CAM.GLOBAL_RESET input signal will trigger the SHUTTER, PRESTROBE and STROBE signals. In this mode, there are no frame counters. The delay counters start decrementing as soon as the GLOBAL_RESET signal is asserted. The polarity of the GLOBAL_RESET signal is set with TCTRL_CTRL.GRESETPOL .	RW	0x0
26	STRBPSTRBPOL	Sets the polarity of the strobe and prestrobe signals. 0x0: Active high 0x1: Active low	RW	0
25	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0
24	SHUTPOL	Sets the polarity of the mechanical shutter signal: CAM.SHUTTER 0x0: Active high 0x1: Active low	RW	0
23	STRBEN	Flash strobe signal enable. If enabled, the STROBE signal will be asserted after TCTRL_FRAME.STRB frames have been received and a delay of TCTRL_STRB_DELAY cycles have passed. The STROBE signal is asserted for TCTRL_STRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal shall not be disabled by software.	RW	0
22	PSTRBEN	Flash prestrobe signal enable. If enabled, the PRESTROBE signal will be asserted after TCTRL_FRAME.PSTRB frames have been received and a delay of TCTRL_PSTRB_DELAY cycles have passed. The PRESTROBE signal is asserted for TCTRL_PSTRB_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal shall not be disabled by software.	RW	0

Bits	Field Name	Description	Type	Reset
21	SHUTEN	Mechanical shutter signal enable. If enabled, the SHUTTER signal will be asserted after TCTRL_FRAME.SHUT frames have been received and a delay of TCTRL_SHUT_DELAY cycles have passed. The SHUTTER signal is asserted for TCTRL_SHUT_LENGTH cycles. After the signal assertion, the enable bit is automatically cleared to 0. This signal shall not be disabled by software.	RW	0
20:19	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
18:10	DIVC	Sets the clock divisor value for the CNTCLK clock generation based on the CAM.MCLK input clock. CNTCLK is an internal clock used by the TIMING CTRL module counters. Usually, CNTCLK = CAM.MCLK / DIVC, except for some particular values shown hereafter. 0x0: No clock. CNTCLK is gated.	RW	0x000
9:5	DIVB	Sets the clock divisor value for the CAM.XCLKB clock generation based on the CAM.MCLK input clock. Usually, CAM.XCLKB = CAM.MCLK / DIVB, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset. 0x0: CAM.XCLKB = stable low level. Divider disabled. 0x1: CAM.XCLKB = stable high level. Divider disabled. 0x1F: CAM.XCLKB = CAM.XCLK. Bypass.	RW	0x00
4:0	DIVA	Sets the clock divisor value for the CAM.XCLKA clock generation based on the CAM.MCLK input clock. Usually, CAM.XCLKA = CAM.MCLK / DIVA, except for some particular values shown hereafter. This bit field is not reset by a soft reset; a hard reset is required. It enables to keep the clock configuration stable through a soft reset. 0x0: CAM.XCLKA = stable low level. Divider disabled. 0x1: CAM.XCLKA = stable high level. Divider disabled. 0x1F: CAM.XCLKA = CAM.XCLK. Bypass.	RW	0x00

Table 6-129. CBUFFx_CTRL

Address Offset	0x0000 0020 + (x * 0x4)	Index	x = 0 to 1
Physical Address	0x480B C120 + (x * 0x4)	Instance	ISP_CBUFF
Description	Circular buffer x control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																WCOUNT		BCF				ALLOW_NW_EQ_CPUW	DONE	RWMODE	ENABLE						

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000000
9:8	WCOUNT	Window count 0x0: 2 windows 0x1: 4 windows 0x2: 8 windows 0x3: 16 windows	RW	0x0
7:4	BCF	This register controls the bandwidth control feedback loop output. Functionality depends on subsystem integration. 0: Control loop disabled. Data read from memory is free running. 1-15: The control feedback loop signal is asserted when the window count available for ISP is below () the threshold. In other words at least (=) BCF windows are available for ISP access when this signal is released.	RW	0x0
3	ALLOW_NW_EQ_CPUW	Allow NW=CPUW. Better buffer utilization when ISP does not use the next write window. 0x0: When the CPUW and the NW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when - the CPU has received an READY IRQ for that window indicating that it can be accessed and - the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity. 0x1: When the CPUW and the CW pointers designate the same window and accesses are effectively performed to those windows an overflow event occurs. This happens when - the CPU has received an READY IRQ for that window indicating that it can be accessed and - the ISP performs an access to that window. ISP accesses are tracked based on OCPI activity.	RW	0x0
2	DONE	Write this bit to 1 to indicate the CPU has finished processing its physical buffer. This bit is automatically cleared by hardware, reads always return 0. 0x0: No effect. 0x1: The CPU has completely processed the CPUW physical buffer.	W	0x0

Bits	Field Name	Description	Type	Reset
1	RWMODE	Selects read or write mode 0x0: Write mode. HW writes and CPU reads the physical space. CPU accesses are out of CBUFF module's scope, therefore only writes are permitted between CBUFF0_START and CBUFF0_END. 0x1: Read mode. HW reads and CPU writes the physical space. CPU accesses are out of CBUFF module's scope; therefore only reads are permitted between CBUFF0_START and CBUFF0_END.	RW	0x0
0	ENABLE	Enable/disable 0x0: Disables the circular buffer 0; this resets the internal state of circular buffer 0. All accesses received on OCPI are transmitted to OCPO without modification. Disabling the module takes effect immediately. It is SW responsibility to ensure that no more accesses to CBUFF0 are outstanding before disabling the module. Otherwise memory corruption may occur. 0x1: Enable the circular buffer 0. All accesses between CBUFF0_START and CBUFF0_END are processed by the module.	RW	0x0

6.6.3.2 Camera ISP CCP2 Register Description

Table 6-146. CCP2_REVISION

Address Offset	0x0000 0000	Instance	ISP_CCP2
Physical Address	See Table 6-145		
Description	MODULE REVISION This register contains the IP revision code in binary coded digital. For example, 0x01 = revision 0.1 and 0x21 = revision 2.1		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REV															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write 0's for future compatibility. Reads returns 0.	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision	R	TI internal data

Table 6-148. CCP2_SYSCONFIG

Address Offset	0x0000 0004	Instance	ISP_CCP2
Physical Address	0x480B C404		
Description	SYSTEM CONFIGURATION REGISTER This register is the Interconnect-socket system configuration register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MSTANDBY_MODE		RESERVED										SOFT_RESET	AUTO_IDLE		

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00000
13:12	MSTANDBY_MODE	Sets the behavior of the master port power management signals 0x0: Force-standby. MStandby is asserted only when the module is disabled. 0x1: No-standby. MStandby is never asserted. 0x2: Smart-standby: MStandby is asserted based on the activity of the module. The module tries to go to standby during the vertical blanking period.	RW	0x0
11:2	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x000
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. Read returns 0. 0x0: Normal mode 0x1: The module is reset.	RW	0x0
0	AUTO_IDLE	Internal Interconnect clock-gating strategy 0x0: Interconnect clock is free-running. 0x1: Automatic Interconnect clock-gating strategy is applied based on Interconnect interface activity.	RW	0x1

Table 6-164. CCP2_CTRL

Address Offset	0x0000 0040	Instance	ISP_CCP2
Physical Address	0x480B C440		
Description	GLOBAL CONTROL REGISTER. This register controls the CCP2B RECEIVER module. This register is not modified dynamically (except IF_EN bit field).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0									
FRACDIV																	POSTED	DBG_EN	VP_CLK_POL	VP_ONLY_EN	INV	VP_CLK_FORCE_ON	RESERVED	BURST	MODE	FRAME	IO_OUT_SEL	PHY_SEL	IF_EN											

Bits	Field Name	Description	Type	Reset
31:15	FRACDIV	Fractional clock divider control for the video port. The means video port clock is VPBASECLOCK * FRACDIV/65536.	RW	0x10000
14	POSTED	Selects between posted and nonposted writes 0x0: Nonposted 0x1: Posted	RW	0x0
13	DBG_EN	Enables the debug mode 0x0: Disable 0x1: Enable		0x0
12	VP_CLK_POL	VP clock polarity 0x0: The CCP2B RECEIVER module writes the data on the VP on the pixel clock falling edge. The module connected to the VP samples the data on the pixel clock rising edge. 0x1: The CCP2B RECEIVER module writes the data on the VP on the pixel clock raising edge. The module connected to the VP samples the data on the pixel clock falling edge.	RW	0x0

Bits	Field Name	Description	Type	Reset
11	VP_ONLY_EN	VP only enable 0x0: The VP is enabled and the Interconnect master port is enabled. 0x1: The VP is enabled and the Interconnect master port is disabled. The embedded data and pixel data are output on the VP.	RW	0x0
10	INV	Strobe/clock inversion control signal 0x0: Not inverted 0x1: Inverted	RW	0x0
9	VP_CLK_FORCE_ON	Controls video port clock gating during frame blanking periods. 0x0: The video port clock is gated during vertical blanking periods. 0x1: The video port clock is free-running during vertical blanking periods.	RW	0x1
8	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
7:5	BURST	Forces the write burst size used by the module The write burst size must never exceed the output FIFO size. The output FIFO size can be read with the CCP2_GNQ.FIFODEPTH bit field. 0x0: 1 x 64-bit burst = single request 0x1: 2 x 64-bit bursts 0x2: 4 x 64-bit bursts 0x3: 8 x 64-bit bursts 0x4: 16 x 64-bit bursts	RW	0x0
4	MODE	Selects the receiver operating mode 0x0: MIPI CSI1-compatible mode. When this bit is set, all CCP2B settings are ignored. If the settings are not set correctly to MIPI CSI1 values, the behavior of the receiver is unpredictable. 0x1: CCP2B compatible mode	RW	0x0
3	FRAME	Set the modality in which IF_EN works. 0x0: When SW writes IF_EN = 0, the interface is disabled immediately. 0x1: When SW writes IF_EN = 0, the interface is disabled after the next FEC synchronization code.	RW	0x0
2	IO_OUT_SEL	IO cell output mode selection 0x0: RESERVED 0x1: MUST BE SET TO 1, IO output is parallel: DATA32, DATATOG, SYNTOG. The SSC_IRQ error can be triggered in this configuration.	RW	0x0
1	PHY_SEL	Physical layer protocol selection. Applies for all logical channels 0x0: Data/clock physical layer 0x1: Data/strobe physical layer	RW	0x0
0	IF_EN	Enables the physical interface to the module 0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled on the next FEC synchronization code. If FRAME=1, it is advised to disable the logical channels (CCP2_LCX_CTRL.CHAN_EN = 0) before writing IF_EN = 0. 0x1: The interface is enabled immediately, the data acquisition starts on the next FSC synchronization code. Writing 1 to this register when the current value is 0 clears the output FIFO. The pixel data of the following frame is written in the PING buffer; that is, the CCP2_LCX_CTRL.PING_PONG bits are also reset to 1.	RW	0x0

Physical Address	0x480B C450 + (x * 0x30)	Instance	ISP_CCP2
Description	CONTROL REGISTER - LOGICAL CHANNEL x. This register controls logical channel x. This register is shadowed; modifications are taken into account after the next FSC synchronization code.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0				
COUNT								RESERVED								ALPHA								FORMAT								REGION_EN		CHAN_EN	

Bits	Field Name	Description	Type	Reset
31:24	COUNT	Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the COUNT_IRQ interrupt is triggered and CHAN_EN is set to '0'. Writes to this bit field are controlled by the COUNT_UNLOCK bit. COUNT can be overwritten dynamically with a new count value. 0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.	RW	0x00
23:20	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
19	CRC_EN	Enables the cyclic redundancy check. 0x0: Disabled 0x1: Enabled	RW	0
18	DPCM_PRED	Selects the DPCM predictor to be used for the RAW6+DPCM10, RAW7+DPCM10 and RAW8+DPCM12 data formats. The RAW8+DPCM10 data format always use the simple predictor. 0x0: The advanced predictor is used 0x1: The simple predictor is used.	RW	0
17	PING_PONG	Indicates whether the PING or PONG destination address (CCP2_LC0_DAT_PING_ADDR or CCP2_LC0_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC sync code. Read 0x0: PING buffer Read 0x1: PONG buffer	R	1
16	COUNT_UNLOCK	Unlock writes to the COUNT bit field. Write 0x0: COUNT bit field is locked. Writes have no effect Write 0x1: COUNT bit field is unlocked. Writes are possible.	W	0
15:8	ALPHA	Alpha value for RGB888 and RGB444.	RW	0x00
7:2	FORMAT	Data format selection. 0x0: YUV422 BIG ENDIAN 0x1: YUV422 LITTLE ENDIAN 0x2: YUV420 0x3: YUV422 + VP or RAW8 + VP 0x4: RGB444 + EXP16 0x5: RGB565 0x6: RGB888 0x7: RGB888 + EXP32 0x8: RAW6 + EXP8 0x9: RAW6 + DPCM10 + EXP16 0xA: RAW6 + DPCM10 + VP 0xB: RAW10 - RAW6 DPCM RAW10 data from sensor is DPCM compressed into RAW6 before it is send to memory. Table 6-174. CCP2_LCx_CODE

Address Offset	0x0000 0054 + (x * 0x30)	Index	x = 0 to 3
Physical Address	0x480B C454 + (x * 0x30)	Instance	ISP_CCP2
Description	CODE REGISTER - LOGICAL CHANNEL x. This register sets the codes that are used in the 32-bit synchronization codes to recognize the logical channel, frame start, frame end, line start, and line end codes. This register applies for logical channel x only. The default values should not be modified. Updating this register with new codes under a flowing serial transmission on that channel causes unexpected results.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								CHAN_ID				FEC				FSC				LEC			LSC								

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x000
19:16	CHAN_ID	Logical channel x identifier The channel identifier is located between bits 4 to 7 in the 32-bit synchronization codes.	RW	0x0 for LC0 0x1 for LC1 0x2 for LC2 0x3 for LC3
15:12	FEC	Logical channel x frame end synchronization code identifier The synchronization code identifier is between bits 0 to 3 in the 32-bit synchronization codes.	RW	0x3
11:8	FSC	Logical channel x frame start synchronization code identifier The synchronization code identifier is between bits 0 to 3 in the 32-bit synchronization codes.	RW	0x2
7:4	LEC	Logical channel x line end synchronization code identifier The synchronization code identifier is between bits 0 to 3 in the 32-bit synchronization codes.	RW	0x1
3:0	LSC	Logical channel x line start synchronization code identifier The synchronization code identifier is between bits 0 to 3 in the 32-bit synchronization codes.	RW	0x0

Table 6-192. CCP2_LCx_DAT_OFST

Address Offset	0x0000 0078 + (x * 0x30)	Index	x = 0 to 3
Physical Address	0x480B C478 + (x * 0x30)	Instance	ISP_CCP2
Description	DATA MEMORY ADDRESS OFFSET REGISTER - LOGICAL CHANNEL x. This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR . For example, it enables 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data have the same data format. Note that the 5 LSBs are ignored: the offset shall be a multiple of 32 bytes. The use of this register is limited to the following data formats: YUV422 little-endian, YUV422 big-endian, RGB565, RGB444 + EXP16, RGB888 + EXP32. This register is shadowed; modifications are taken into account after the next FSC synchronization code.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFST																RESERVED															

Bits	Field Name	Description	Type	Reset
31:5	OFST	Line offset programmed in bytes If OFST = 0, the data are written contiguously in memory. Otherwise, OFST sets the destination offset between the first pixel of the previous line and the first pixel of the current line. ⁽¹⁾	RW	0x0000000
4:0	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00

⁽¹⁾ An Interconnect access (read/write) is required to properly update the CCP2_LCx_DAT_OFST register.

Table 6-194. CCP2_LCM_CTRL

Address Offset	0x0000 01D0	Instance	ISP_CCP2
Physical Address	0x480B C5D0		
Description	Control register for the memory channel. It defines the data format of the source frame stored in memory and how this frame is processed.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
DST_PACK	RESERVED	RESERVED	RESERVED		DST_FORMAT			SRC_PACK	RESERVED	RESERVED	RESERVED		SRC_FORMAT			RESERVED								BURST_SIZE	READ_THROTTLE	DST_PORT	RESERVED	CHAN_EN			

Bits	Field Name	Description	Type	Reset
31	DST_PACK	Data is packed before it is sent to memory. Applies to RAW6, RAW7, RAW10, and RAW12 only. 0x0: Disabled 0x1: Enabled	RW	0x0
30	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
39	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
27	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
26:24	DST_FORMAT	Output format selection Not every combination of input and output formats is possible. See Table 6-25, Camera ISP CSI1/CCP2B Memory-to-Video Processing Hardware Supported Formats 0x0: RAW6 0x1: RAW7 0x2: RAW8 0x3: RAW10 0x4: RAW12 0x5: RAW14 0x6: RAW16	RW	0x0
23	SRC_PACK	Data stored in memory is packed and must be unpacked. 0x0: Disabled 0x1: Enabled	RW	0x0
22	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
21	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
19	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
18:16	SRC_FORMAT	Data format of the data stored in memory Because there is no header embedded in the data sent to memory, the user is responsible for choosing the correct format. 0x0: RAW6 0x1: RAW7 0x2: RAW8 0x3: RAW10 0x4: RAW12 0x5: RAW14 0x6: RAW16	RW	0x0
15:8	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00
7:5	BURST_SIZE	Defines the burst size of the master read port 0x0: 1x 64-bit burst = single request 0x1: 2x 64-bit bursts 0x2: 4x 64-bit bursts 0x3: 8x 64-bit bursts 0x4: 16x 64-bit bursts 0x5: 32x 64-bit bursts	RW	0x0

Bits	Field Name	Description	Type	Reset
4:3	READ_THROTTLE	Limit maximum data read speed for memory-to-memory operation. 0x0: Full speed. Throughput is limited by internal processing capabilities. 0x1: 1/2 speed 0x2: 1/4 speed 0x3: 1/8 speed	RW	0x0
2	DST_PORT	Select the destination port. 0x0: Data is sent to video port; it is always sent without compression or packing. The CCP2_LCM_CTRL.DST_PACK , CCP2_LCM_DST_ADDR and CCP2_LCM_DST_OFST registers have no effect. 0x1: Data is sent to memory.	RW	0x0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
0	CHAN_EN	Enables the read from the memory channel Before enabling the memory read channel, the software must: - Disable the physical interface using the IF_EN bit - Wait until disabling of the physical interface is effective (depends on the FRAME bit) Read from memory starts when this bit is set; therefore, all CCP2_LCM_x registers must be configured correctly before the bit is set. This bit is cleared by hardware at the end of the frame. 0x0: Disabled 0x1: Enabled	RW	0x0

Table 6-202. CCP2_LCM_SRC_ADDR

Address Offset	0x0000 01E0	Instance	ISP_CCP2
Physical Address	0x480B C5E0		
Description	Memory channel source address register This register sets the 32-bit memory address where the pixel data are stored. The 5 LSBs are ignored; the address is aligned on a 32-byte boundary.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ADDR																RESERVED															

Bits	Field Name	Description	Type	Reset
31:5	ADDR	27 MSBs of the 32-bit address	RW	0x0000000
4:0	RESERVED	5 LSBs of the 32-bit address Write 0s for future compatibility. Read returns 0.	RW	0x00

Table 6-204. CCP2_LCM_SRC_OFST

Address Offset	0x0000 01E4	Instance	ISP_CCP2
Physical Address	0x480B C5E4		
Description	Memory channel source offset register. This register sets the offset, which is applied on the source address after each line is read from memory. For example, it enables 2D data transfers of the pixel data from a frame buffer. In such case, the pixel data and frame buffer data have the same data format. The 5 LSBs are ignored; the offset is a multiple of 32 bytes.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFST																RESERVED															

Bits	Field Name	Description	Type	Reset
31:5	OFST	Line offset programmed in bytes If OFST = 0, the data are read contiguously from memory. Otherwise, OFST sets the source offset between the first pixel of the previous line and the first pixel of the current line.	RW	0x0000000
4:0	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00

Table 6-208. CCP2_LCM_DST_OFST

Address Offset	0x0000 01EC	Instance	ISP_CCP2
Physical Address	0x480B C5EC		
Description	Memory channel destination offset register. This register sets the offset, which is applied on the destination address after each line is written to memory. For example, it enables 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data have the same data format. The 5 LSBs are ignored; the offset is a multiple of 32 bytes.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
OFST																RESERVED															

Bits	Field Name	Description	Type	Reset
31:5	OFST	Line offset programmed in bytes If OFST = 0, the data are written contiguously to memory if possible. At the end of a line, only full 32-bit words are written, eventually creating gaps at the end of lines. Otherwise, OFST sets the destination offset between the first pixel of the previous line and the first pixel of the current line.	RW	0x0000000
4:0	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00

Table 6-215. CCDC_SYN_MODE

Address Offset	0x0000 0008	Instance	ISP_CCDC
Physical Address	0x480B C608		
Description	SYNC and mode set register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								SDR2RSZ	VP2SDR	WEN	VDHLEN	FLDSTAT	LPF	INPMOD	PACK8	DATSIZ				FLDMODE	DATAPOL	EXWEN	FLDPOL	HDPOL	VPOL	FLDOUT	VDHOUT				

Bits	Field Name	Description	Type	Reset
31:20	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
19	SDR2RSZ	Memory port output into the RESIZER input. Controls whether or not the memory port output data are forwarded to the RESIZER module input port. This does not depend on the state of the CCDC_SYN_MODE.WEN bit. This bit must only be set if the CCDC module receives directly YUV422 data. The input frame size to the RESIZER module is the same as the output frame size to the memory port. The data are simultaneously written to memory if the WEN bit is set while sending the same data to the RESIZER module. The PREVIEW module can also write to the RESIZER module: this bit takes precedence over the PREVIEW module settings. This bit is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
18	VP2SDR	Video port output enable to the output formatter. Controls whether the video port data is forwarded to the output formatter or not. If CCDC_SYN_MODE.WEN = 1, the video port data is written to memory. Note that if field is set, then SDRAM line (VERT_START.SLVx) and pixel start (HORZ_INFO.SPH) are with respect to the video port output (and not the original input) This bit field is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0
17	WEN	Data write enable. Controls whether the CCDC module output data are written to memory or not. This bit field is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0x0
16	VDHDEN	Timing generator enable. If HS/VS sync pulses are defined as output signals, activates the internal timing generator. If HS/VS sync pulses are defined as input signals, activates internal timing generator to synchronize with HS/VS. This bit must be set to 1 when HS and VS signals are used. 0x0: Disable 0x1: Enable	RW	0x0
15	FLDSTAT	cam_fld signal status. This bit field applies only if the CCDC module is configured to work in interlaced mode: CCDC_SYN_MODE.FLDMODE = "interlaced". It indicates the status of the current field. 0x0: Odd field 0x1: Even field	R	0x0
14	LPF	Three-tap low pass (antialiasing) filter enable. This bit field is latched by the VS sync pulse. 0x0: Filter is disabled. 0x1: Filter is enabled.	RW	0x0
13:12	INPMOD	cam_d format in SYNC mode. Sets the data input format. 0x0: Raw data 0x1: YCbCr data on 16 bits. It is required to enable the 8 to 16-bit bridge in the ISP_CTRL register. 0x2: YCbCr data on 8 bits.	RW	0x0
11	PACK8	Data packing. Sets the data packing configuration when the data is written to memory. 0x0: Normal mode: 16 bits/pixel. 0x1: Pack mode: 8 bits/pixel.	RW	0x0
10:8	DATSIZ	cam_d signal width in SYNC mode. Valid only when CCDC_SYN_MODE.INPMOD = "raw data". 0x0: cam_d is 8 bits but the 8 to 16-bit bridge is enabled in the ISP_CTRL register. 0x4: cam_d is 12 bits 0x5: cam_d is 11 bits 0x6: cam_d is 10 bits 0x7: cam_d is 8 bits	RW	0x0

Bits	Field Name	Description	Type	Reset
7	FLDMODE	cam_fld signal mode. 0x0: Progressive mode. cam_fld not used. 0x1: Interlaced mode. cam_fld used.	RW	0x0
6	DATAPOL	cam_d signal polarity. 0x0: Normal 0x1: One's complement	RW	0x0
5	EXWEN	External write enable selection. The cam_wen signal can be used as an external memory write-enable signal. The data is stored to memory only if cam_hs, cam_vs and cam_wen signals are asserted. 0x0: cam_wen is not used. 0x1: cam_wen is used	RW	0x0
4	FLDPOL	cam_fld signal polarity. 0x0: Positive 0x1: Negative	RW	0x0
3	HDPOL	Sets the cam_hs signal polarity. 0x0: Positive 0x1: Negative	RW	0x0
2	VDPOL	cam_vs signal polarity 0x0: Positive 0x1: Negative	RW	0x0
1	FLDOUT	cam_fld signal direction. 0x0: Input 0x1: Output	RW	0x0
0	VDHDOUT	cam_hs and cam_vs signal directions. 0x0: Input 0x1: Output	RW	0x0

PPLN																HLPRF															

Bits	Field Name	Description	Type	Reset
31:16	PPLN	Pixels per line Sets the number of pixel clock periods in one line. HD period = (PPLN + 1) pixel clocks. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). This bit field is latched by the VS sync pulse	RW	0x0000

Bits	Field Name	Description	Type	Reset
15:0	HLPFR	<p>Half line per field or frame Sets the number of half lines per frame or field. VD period = (HLPFR + 1)/2 lines. Not used when HS/VS sync pulses are input signals (CCDC_SYN_MODE.VDHDOUT = 0). Sets the internal timing generator to generate the correct number of HS pulses in between two VS pulses. If the sensor is interlaced, with a total of N lines, then this field must be set to N. This means that N half lines are written for each field. If the sensor is progressive, then this register must be set to be twice the number of lines to be written. For example, if sensor outputs N lines, this field must be set to 2N. This bit field is latched by the VS sync pulse.</p>	RW	0x0000

Table 6-243. CCDC_FPC

Address Offset	0x0000 0040	Instance	ISP_CCDC
Physical Address	0x480B C640		
Description	FAULT PIXEL CORRECTION REGISTER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																FPER	FPCEN	FPNUM													

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
16	FPERR	<p>Fault pixel correction error</p> <p>This bit is set when the CCDC module is unable to fetch the required fault pixel table entry in time. Write 1 to clear the error or end_of_frame clears it automatically for the next frame.</p> <p>For example, the current pixel being processed has coordinates of 256/512 (256th line and 512th pixel in that line) and it must be corrected. If the entry in the fault pixel table that must be used has coordinates 256/256, then the current pixel cannot be corrected since the correct entry is not loaded in time.</p> <p>Note that there is no error recovery mechanism in the CCDC; if this bit is set at anytime in a frame, there are no more fault pixels corrected in that frame. Firmware is responsible for making sure that there is enough bandwidth in the system to allow for loading of the fault pixel table. Alternately, decreasing the frequency of the fault pixels to be corrected enhances the chances of this bit not being set.</p> <p>0x0: No error 0x1: Error</p>	RW	0x0
15	FPCEN	<p>Fault pixel correction enable.</p> <p>Upon setting this bit, and as long as it remains enabled, the fault pixel logic continues to request data and just start over for next frame once the last data of current frame has been received. As soon as the register is set the data are fetched. To disable fault pixel correction, users can write a 0 at any time. However, the disabling only applies after the current frame is processed (busy bit for current frame is 0)</p> <p>This bit should only be written after the FPC_ADDR register below has been set. Also, the other fields in this register have to be set prior to enabling this bit. The required process is: Write(FPC_ADDR) Write(FPC) with this bit (FPC.FPCEN) turned off Write(FPC) with this bit (FPC.FPCEN) turned on while other fields are same as previous write</p> <p>0x0: Disable 0x1: Enable</p>	RW	0x0
14:0	FPNUM	<p>Number of fault pixels to be corrected in the frame</p> <p>This field should not be changed when the FPCEN is enabled at any time</p>	RW	0x0000

RESERVED								VPIF_FRQ				VPEN	VPIN			PLEN_EVEN			PLEN_ODD		LNUM	LNALT	FMTEN								

Bits	Field Name	Description	Type	Reset
31:22	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000
21:16	VPIF_FRQ	Video port data ready frequency. This field allows the firmware to control the rate at which the video port delivers new data to the other modules (PREVIEW, H3A, and HIST modules). In effect, this register controls the raw output bandwidth of the PREVIEW, H3A, and HIST. Depending on the input sensor clock, the user can set this field appropriately and balance the bandwidth requirements to memory. Given a pixel clock, one shall set this bit field with the higher divisor value to lower the memory bandwidth requirement. The video port clock is Interconnect/(VPIF_FRQ+2). The valid range for VPIF_FRQ is 0..62	RW	0x00
15	VPEN	Video port enable. This bit shall be enabled to send data to the PREVIEW, H3A and HIST modules. 0x0: Disable 0x1: Enable	RW	0
14:12	VPIN	10-bit input select for video port. 0x3: bits 12-3 0x4: bits 11-2 0x5: bits 10-1 0x6: bits 9-0	RW	0x4
11:8	PLEN_EVEN	Number of program entries in even line minus 1. If the desired number of program entries is 8, then the value shall be set to 7.	RW	0x0

Bits	Field Name	Description	Type	Reset
7:4	PLEN_ODD	Number of program entries in odd line minus 1. If the desired number of program entries is 8, then the value shall be set to 7.	RW	0x0
3:2	LNUM	Number of output lines from 1 input line 0x0: 1 line 0x1: 2 lines 0x2: 3 lines 0x3: 4 lines	RW	0x0
1	LNALT	Line alternating mode enable. In Line Alternating Mode, even and odd lines are swapped. 0th line output as 1st line and 1st line output as 0th line, and so on. If this bit field is set, the start and number of lines for the formatter (FMTVERT below) should be even. The FMTEN field below should be set in addition for this field to function 0x0: Enable. Normal mode 0x1: Disable. Line alternating mode	RW	0
0	FMTEN	Formatter enable. This bit is latched by the VS sync pulse. 0x0: Disable 0x1: Enable	RW	0

30:17	VERT_NUM	Number of vertical lines to clock out the video. If the data reformatter is turned off, then the number of lines that can be clocked out of the video port must be at least 1 line less than the number of lines input from the sensor. If the data reformatter is turned on, then the number of lines that can be clocked out of the video port must be less than $(CCDC_FMT_VERT.FMTLNV - 1) * (CCDC_FMTCFG.LNUM + 1)$. The video port output VS pulse is generated right from the first video port input VS itself.	RW	0x0000
16:4	HORZ_NUM	Number of horizontal pixel to clock out the video port. The minimum value allowed is 2 pixels. The maximum offset allowed is 1376 if original input is broken down to 4 lines. The maximum offset allowed is 1376 if original input is broken down to 3 lines. The maximum offset allowed is 2*1376 if original input is broken down to 2 lines. The maximum offset allowed is 4*1376 if original input is broken down to 1 line.	RW	0x0000
3:0	HORZ_ST	Horizontal start pixel in each output line. The maximum value allowed is 15. The video port output HSYNC pulse is generated from this position on for each line. To be able to select an offset higher than 15, the input settings to the data reformatter must be configured appropriately. The purpose of this parameter is to allow for sensors that can read out a parallelogram image rather than a rectangular image.	RW	0x0

Bits	Field Name	Description	Type	Reset
31:15	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x00000
14:12	GAIN_MODE_M	Define the horizontal dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (M=4) 0x3: Paxel is 8 pixels tall (M=8) 0x4: Paxel is 16 pixels tall (M=16) 0x5: Paxel is 32 pixels tall (M=32) 0x6: Paxel is 64 pixels tall (M=64)	RW	0x6
11	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
10:8	GAIN_MODE_N	Define the vertical dimension of a paxel. Possible values are listed below 0x2: Paxel is 4 pixels tall (N=4) 0x3: Paxel is 8 pixels tall (N=8) 0x4: Paxel is 16 pixels tall (N=16) 0x5: Paxel is 32 pixels tall (N=32) 0x6: Paxel is 64 pixels tall (N=64)	RW	0x6
7	BUSY	Module busy or idle 0x0: The module is idle 0x1: The module is busy	R	0x0

Bits	Field Name	Description	Type	Reset
6	AFTER_REFORMATTER	Chooses if lens-shading compensation is done before or after data reformatting 0x0: Lens-shading is done before data reformatting. H3A, HIST and PREVIEW receives shading compensated data 0x1: Data received by H3A is not compensated. Data received by PREVIEW and HIST is compensated.	RW	0x0
5:4	RESERVED	Write 0s for future compatibility. Reads return 0.	RW	0x0
3:1	GAIN_FORMAT	Sets gain table format 0x0: Coded as 8-bit fraction Range from 0 to 255/256 0x1: Coded as 8-bit fraction + 1.0 of base. Range from 1 to 1+255/256 0x2: Coded as 1-bit integer, 7-bit fraction. Range from 0 to 1+127/128 0x3: Coded as 1-bit integer, 7-bit fraction + 1.0 Range from 1 to 2+127/128 0x4: Coded as 2-bit integer, 6-bit fraction Range from 0 to 3+63/64 0x5: Coded as 2-bit integer, 6-bit fraction + 1.0 Range from 1 to 4+63/64 0x6: Coded as 3-bit integer, 5-bit fraction Range from 0 to 7+31/32 0x7: Coded as 3-bit integer, 5-bit fraction + 1.0 Range from 1 to 8+31/32	RW	0x0
0	ENABLE	Enables/disables LSC 0x0: Disables the module at the end of the current frame. Video data is transmitted without modification when LSC is disabled. The BUSY bit can be used to poll when access to SBL buffer can be used by the preview module. 0x1: Enables the module. Module starts fetching the gain table as soon it is started. Firmware has to make sure it has been correctly initialized before starting the module. Data processing is only effective at the start of the next frame. Note that preview module dark frame subtract must be disabled because there is only one shared read port.	RW	0x0

Table 6-356. PRV_PCR

Address Offset	0x0000 0004	Instance	ISP_PREVIEW
Physical Address	0x480B CE04		
Description	PERIPHERAL CONTROL REGISTER All the fields in this register can be altered even when the PREVIEW module is busy. Changes take place only for the next frame.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
DRK_FAIL	RESERVED	DCOR_METHOD	DCOREN	GAMMA_BYPASS	RESERVED	SCOMP_SFT	SCOMP_EN	SDRPORT	RSZPORT	YCPOS	SUPEN	YNENHEN	CFAFMT				CFAEN	NFEN	HMEDEN	DRKFCAP	DRKFEN	INVALAW	WIDTH	ONESHOT	SOURCE	BUSY	ENABLE						

Bits	Field Name	Description	Type	Reset
31	DRK_FAIL	Dark frame subtract fail status. Write 1 to clear this bit. Reset to zero for the next frame. When the error is triggered, dark frame subtract is abandoned for the current frame, dark frame subtract resumes for next frame (but bit is not cleared unless explicitly done by firmware). 0x0: No error 0x1: Error	RW	0x0
30:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
28	DCOR_METHOD	Defect correction method. 0x0: MinMax 0x1: MinMax2 (Couplet defect correction)	RW	0x0
27	DCOREN	Defect correction enable This bit enables or disables the defect correction. The PRV_PCR.DCOR_METHOD and PRV_CDC_THRx registers must be configured for correct operation. 0x0: Disable defect correction 0x1: Enable defect correction	RW	0x0
26	GAMMA_BYPASS	Bypass, the output is set to the 8 MSB of the 10-bit input. 0x0: No bypass. 0x1: Bypass, the output is set to the 8 MSB of the 10-bit input.	RW	0x0
25	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
24:22	SCOMP_SFT	Shading compensation shift value after multiplication. The right-shift range is 0 to 7.	RW	0x0
21	SCOMP_EN	Shading compensation enable instead of dark frame The 8-bit value loaded from memory is multiplied by the current pixel instead of subtracting it. Note that the dark frame subtract (DRKFEN) must be enabled in addition to this bit being active to perform shading compensation. 0x0: Disable. Dark frame subtract can be used. 0x1: Enable. Dark frame subtract cannot be used.	RW	0x0

Bits	Field Name	Description	Type	Reset
20	SDRPORT	PREVIEW module memory output port enable. This bit enables or disables the data transfer from the PREVIEW module to the memory. 0x0: Disable 0x1: Enable	RW	0x1
19	RSZPORT	RESIZER module output port enable. This bit enables or disables the data transfer between the PREVIEW and RESIZER modules. Controls whether or not SDRAM output data is forwarded to the resizer input port. This control bit does not depend on the state of the former SDRPORT bit. Data is simultaneously written to SDRAM (if SDRPORT bit is set) while sending the same data to the resizer as input. Note that the CCDC is also capable of directly writing to the resizer input port. The CCDC setting takes precedence over the preview engine setting. 0x0: Disable 0x1: Enable	RW	0x0
18:17	YCPOS	(CRYCBY) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0) 0x0: (YCRYCB) Y1(31:24) Cr0(23:16) Y0(15:8) Cb0(7:0) 0x1: (YCBYCR) Y1(31:24) Cb0(23:16) Y0(15:8) Cr0(7:0) 0x2: (CBYCRY) Cb0(31:24) Y1(23:16) Cr(15:8) Y0(7:0) 0x3: (CRYCBY) Cr0(31:24) Y1(23:16) Cb0(15:8) Y0(7:0)	RW	0x0
16	SUPEN	Color suppression. 0x0: Disable 0x1: Enable	RW	0x0
15	YNENHEN	Non-linear enhancer 0x0: Disable 0x1: Enable	RW	0x0
14:11	CFAFMT	CFA format 0x0: Mode 0: conventional Bayer. 0x1: Mode 1: horizontal 2x downsample. 0x2: Mode 2: bypass CFA stage 0x3: Mode 3: horizontal and vertical 2x downsample. 0x4: Mode 4: Super CCD Honeycom movie mode sensor. 0x5: Mode5: bypass CFA stage .	RW	0x0
10	CFAEN	CFA enable 0x0: Disable 0x1: Enable	RW	0x0
9	NFEN	Noise filter enable 0x0: Disable 0x1: Enable	RW	0x0
8	HMEDEN	Horizontal median filter enable. 0x0: Disable 0x1: Enable	RW	0x0
7	DRKFCAP	Dark frame capture enable. 0x0: Normal processing. 0x1: Capture dark frame.	RW	0x0
6	DRKFEN	Subtract dark frame enable. 0x0: Disable 0x1: Enable	RW	0x0

Bits	Field Name	Description	Type	Reset
5	INVALAW	Inverse A-Law enable. 0x0: Disable 0x1: Enable	RW	0x0
4	WIDTH	Input data width selection. 0x0: 10-bit mode 0x1: 8-bit mode	RW	0x0
3	ONESHOT	One-shot mode selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Continuous mode (through the video port). 0x1: One shot mode.	RW	0x0
2	SOURCE	Input source selection. If this bit is set to 1, it is reset to 0 after the ENABLE bit is asserted. 0x0: Video port (through the CCDC) 0x1: Memory.	RW	0x0
1	BUSY	Busy bit. 0x0: PREVIEW module not busy. 0x1: PREVIEW module busy.	R	0x0
0	ENABLE	Enable bit. If the ONESHOT or SOURCE bit is 1, this bit is reset to 0 after it is asserted 0x0: PREVIEW module disabled. 0x1: PREVIEW module enabled.	RW	0x0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								SPH								RESERVED								EPH							

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
29:16	SPH	Start pixel horizontal. If <code>PRV_PCR.SOURCE == 0</code> (CCDC input) SPH must be = 2.	RW	0x0000
15:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
13:0	EPH	End pixel horizontal. The input width of the preview engine must be a multiple of the average count multiplied by the least common multiple of the odd distance and even distance of the AVE register settings. If <code>PRV_PCR.SOURCE == 0</code> (CCDC input) EPH must be = 2 pixels before the last pixel sent from the CCDC. $PRV_HORZ_INFO.EPH - PRV_HORZ_INFO.SPH + 1$ $MOD ((1 PRV_AVE.COUNT) * LeastCommonMultiple(PRV_AVE.ODDDIST+1, PRV_AVE.EVENDIST+1)) = 0$	RW	0x0000

RADR																															

Bits	Field Name	Description	Type	Reset
31:0	RADR	32-bit read address. Specifies the 32-bit address in memory of the input frame. The lower 5 bits of this register are always treated as 0s. The offset should be aligned on a 32-byte boundary. This field can be altered even when the PREVIEW module is busy. The change takes place only for the next frame (next VS pulse). However, note that reading this register always gives the latest value.	RW	0x00000000

Description	PERIPHERAL CONTROL REGISTER	
Type	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																ONESHOT	BUSY	ENABLE													

Bits	Field Name	Description	Type	Reset
31:3	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000000
2	ONESHOT	One-shot or continuous mode selection. This bit only applies when the image source is CCDC or PREVIEW (RSZ_CNT INPSRC =0) 0x0: Continuous mode. The module must be disabled by software. The disable module is latched at the end of the frame it was written in. 0x1: One shot mode. Enable bit is reset to 0 once the busy bit turns to 1.	RW	0x1
1	BUSY	RESIZER module busy. 0x0: RESIZER module not busy. 0x1: RESIZER module busy.	R	0x0
0	ENABLE	RESIZER module enable. Memory to memory operation: Resizer always operates in one-shot mode in memory to memory operation. Enable bit is reset to 0 once the busy bit turns to 1. CCDC/PREVIEW to memory operation: The resizer operates either in one-shot or continuous mode. The behavior is defined by the RSZ_PCR [2] ONESHOT bit. The enable bit MUST be the last field written to resize a frame. The enable bit can be written when the resizer is busy. 0x0: Disable RESIZER module. 0x1: Enable RESIZER module.	RW	0x0

RESERVED	CBILIN	INPSRC	INPTYP	YCPOS	VSTPH	HSTPH										VRSZ																HRSZ

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
29	CBILIN	Chrominance horizontal algorithm select. Filtering that is same as luminance processing is intended only for downsampling, and bilinear interpolation is intended only for upsampling. 0x0: The chrominance uses the same processing as the luminance. 0x1: The chrominance uses bilinear interpolation processing.	RW	0x0
28	INPSRC	Input source select. NOTE: If this field is set to zero, the resizer input is fed from either the preview engine or the CCDC, but not both. The CCDC and preview engine modules have individual control to feed their output to the resizer input. If both the CCDC and preview engine modules are set to drive the resizer input, the CCDC output takes precedence. 0x0: PREVIEW or CCDC module. 0x1: Memory.	RW	0x0
27	INPTYP	Input type select. 0x0: YUV422 color is interleaved 0x1: Color separate data on 8 bits.	RW	0x0
26	YCPOS	Luminance and chrominance position in 16-bit word 0x0: YC 0x1: CY	RW	0x0
25:23	VSTPH	Vertical starting phase. The phase range is 0 to 7.	RW	0x0
22:20	HSTPH	Horizontal starting phase. The phase range is 0 to 7.	RW	0x0
19:10	VRSZ	Vertical resizing value. (range from 64 - 1024) plus 1 Vertical resizing ratio is 256/(VRSZ+1) For have the correct functionality, must enter the desired value minus 1. For example for a ratio of 1, must enter 255	RW	0x0FF
9:0	HRSZ	Horizontal resizing value. (range from 64 - 1024) plus 1 Horizontal resizing ratio is 256/(HRSZ+1) For have the correct functionality, must enter the desired value minus 1. For example for a ratio of 1, must enter 255	RW	0x0FF

Table 6-433. RSZ_IN_START

Address Offset	0x0000 0010	Instance	ISP_RESIZER
Physical Address	0x480B D010		
Description	INPUT CONFIGURATION REGISTER This register must be used when the input pixel data comes from the PREVIEW module. must be set to 0 is the input pixel data comes from memory.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								VERT_ST								RESERVED								HORZ_ST							

Bits	Field Name	Description	Type	Reset
31:29	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
28:16	VERT_ST	Vertical start line. This field makes sense when the resizer obtains its input from the preview engine/CCDC When the resizer gets its input from SDRAM, this field must be set to 0	RW	0x0000
15:13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:0	HORZ_ST	Horizontal start pixel. Pixels are coded on 16 bits for YUV and 8 bits for color separate data. When the resizer gets its input from SDRAM, this field must be set to = 15 for YUV 16-bit data and = 31 for 8-bit color separate data Horizontal starting pixel value is in number of pixels if input is from SDRAM. If the input to the resizer is from CCDC/preview engine, this field must be programmed as follows: (1) Program this field using number of bytes (twice number of pixels). (2) Change the lowest bit to reflect start position in pixels (effectively change from a value 0 to a value 1 if required)	RW	0x0000

Table 6-514. SBL_PCR

Address Offset	0x0000 0004	Instance	ISP_SBL
Physical Address	0x480B D204		
Description	PERIPHERAL CONTROL REGISTER Note on the overflow bits: the overflow does not prevent the modules to make further requests. The only way to clear the overflow is to reset the bit. After an overflow, the data will be corrupted and the application layer should disregard the data. No software reset is required after an overflow. If the overflow condition is cleared the data will continue to be acquired normally.

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0's for future compatibility. Reads returns 0.	RW	0x00
26	CSI1_CCP2B_CSI2C_WBL_OVF	CSI1/CCP2B or CSI2C Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. Read 0x0: No overflow Read 0x1: Overflow	RW	0
25	CSI2A_WBL_OVF	CSI2A Write buffer memory overflow All DUs have been filled up: overflow. Software has to write 1 to clear the bit. Read 0x0: No overflow Read 0x1: Overflow	RW	0

Bits	Field Name	Description	Type	Reset
24	CCDCPRV_2_RSZ_OVF	<p>CCDC/PRV to RESIZER input overflow</p> <p>This bit is set if the RESIZER input source is set to CCDC/PREVIEW engine when the active data (to be resized) has already showed up at the resizer interface. In such a case, resizing for this frame cannot take place and the bit is set. This scenario can happen when a resize of 4x is required per frame. Therefore, the RESIZER needs to operate in two passes. In the first pass the input data from CCDC/PREVIEW is directly resized and written to memory. In the second pass, the resized data from the first pass is resized again. The next frame from the CCDC/PREVIEW engine should only start after the second pass on the previous frame is complet. This bit indicated the failure status.</p> <p>Software has to write 1 to clear the bit.</p> <p>Note: Ignore the behavior of this field when RSZ_CNT[28] INPSRC = 0x1 (when data comes from memory).</p> <p>Read 0x0: No overflow Read 0x1: Overflow</p>	RW	0
23	CCDC_WBL_OVF	<p>CCDC Write buffer memory overflow</p> <p>All DUs have been filled up: overflow. Software has to write 1 to clear the bit.</p> <p>Read 0x0: No overflow Read 0x1: Overflow</p>	RW	0

Table 6-641. CSI2_SYSCONFIG

Address Offset	0x0000 0010
Physical Address	See Table 6-638
Description	Instance See Table 6-80 SYSTEM CONFIGURATION REGISTER This register is the Interconnect-socket system configuration register.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																MSTANDBY_MODE	RESERVED												SOFT_RESET	AUTO_IDLE	

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000000
13:12	MSTANDBY_MODE	Sets the behavior of the master port power management signals. 0x0: Force-standby. MStandby is only asserted when the module is disabled. 0x1: No-standby. MStandby is never asserted. 0x2: Smart-standby: MStandby is asserted based on the activity of the module. The module will try to go to standby during the vertical blanking period.	RW	0x0
11:2	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000

Bits	Field Name	Description	Type	Reset
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hw. During reads return 0. 0x0: Normal mode. 0x1: The module is reset	RW	0
0	AUTO_IDLE	Internal Interconnect gating strategy 0x0: Interconnect clock is free-running. 0x1: Automatic Interconnect clock gating strategy is applied based on the Interconnect interface activity.	RW	1

Table 6-649. CSI2_CTRL

Address Offset	0x0000 0040
Physical Address	See Table 6-638
Description	Instance See Table 6-80 GLOBAL CONTROL REGISTER This register controls the CSI2 RECEIVER module. This register shall not be modified dynamically (except IF_EN bit field).
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								VP_CLK_EN	RESERVED			VP_ONLY_EN	RESERVED	VP_OUT_CTRL	DBG_EN	RESERVED	ENDIANNESS	FRAME	ECC_EN	RESERVED	IF_EN										

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000
15	VP_CLK_EN	VP clock enable. 0x0: The VP clock is disabled. 0x1: The VP clock is enabled.	RW	0
14:12	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0
11	VP_ONLY_EN	VP only enable. 0x0: The VP is enabled and the Interconnect master port is enabled. 0x1: The VP is enabled and the Interconnect master port is disabled.	RW	0
10	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000
9:8	VP_OUT_CTRL	Video port output clock control. Sets the video port output clock as a function of the interface clock (OCPCLK). 0x0: RESERVED 0x1: Division by 2: video port clock = OCPCLK / 2. 0x2: Division by 3: video port clock = OCPCLK / 3. 0x3: Division by 4: video port clock = OCPCLK / 4. Note: Software must change the reset value that is not appropriate.	RW	0x0
7	DBG_EN	Enables the debug mode. 0x0: Disable 0x1: Enable	RW	0
6:5	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000
4	ENDIANNESS	Select endianness for YUV422 8 bit and YUV420 legacy formats. 0x0: Use native MIPI CSI2 endianness: Little endian for all formats except for YUV422 8b and YUV420 Legacy which a big endian. 0x1: Store all pixel formats little endian.	RW	0
3	FRAME	Set the modality in which IF_EN works. 0x0: If IF_EN = 0 the interface is disabled immediately. 0x1: If IF_EN = 1 the interface is disabled after all FEC sync code have been received for the active contexts.	RW	0
2	ECC_EN	Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0x0: Disabled 0x1: Enabled	RW	0
1	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x000
0	IF_EN	Enables the physical interface to the module. 0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled when each context has received the FEC sync code. 0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing '1' to this register when the current value is '0' has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, i.e., the CSI2_CTX_CTRL.PING_PONG bits are reset to '0' as well.	RW	0

Address Offset	0x0000 0050	Instance	See Table 6-80
Physical Address	See Table 6-638		
Description	PHY configuration register for the PHY associated to the receiver This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED	RESET_CTRL	RESET_DONE	PWR_CMD	PWR_STATUS	PWR_AUTO	RESERVED										DATA2_POL	DATA2_POSITION	DATA1_POL	DATA1_POSITION	CLOCK_POL	CLOCK_POSITION										

Bits	Field Name	Description	Type	Reset
31	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0
30	RESET_CTRL	Controls the reset of the PHY 0x0: PHY reset active. 0x1: PHY reset de-asserted.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using the PPI byte clock from the PHY Read 0x0: Internal module reset is on going. Read 0x1: Reset completed.	R	0
28:27	PWR_CMD	Command for power control of the PHY 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to Ultra Low Power state	RW	0x0

Bits	Field Name	Description	Type	Reset
26:25	PWR_STATUS	Status of the power control of the PHY Read 0x0: PHY in OFF state Read 0x1: PHY in ON state Read 0x2: PHY in Ultra Low Power state	R	0x0
24	PWR_AUTO	Automatic switch between ULP and ON states based on ULPM signals from PHY 0x0: Disable 0x1: Enable	RW	0
23:12	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order 0x1: -/+ pin order	RW	0
10:8	DATA2_POSITION	Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at position 1. 0x2: Data lane 2 is at position 2. 0x3: Data lane 2 is at position 3. Note: If the parallel camera sensor and the other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the SCM.CONTROL_CAMERAx_PHY_CAMMOD bit must be set for CCP2 or CSI2mode, respectively, (even if only one pair is used as GPI for CPI mode). The corresponding DATAx_POSITION bit must be set to 0x0 for the lane in GPI mode.	RW	0x0
7	DATA1_POL	+/- differential pin order of DATA lane 1. 0x0: +/- pin order 0x1: -/+ pin order	RW	0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. The data lane 1 is always present. 0x0: Not used/connected 0x1: Data lane 1 is at position 1. 0x2: Data lane 1 is at position 2. 0x3: Data lane 1 is at position 3. Note: If the parallel camera sensor and the other camera sensor (CCP2 or CSI2) are connected to the same CSIPHY, the SCM.CONTROL_CAMERAx_PHY_CAMMOD bit must be set for CCP2 or CSI2mode, respectively, (even if only one pair is used as GPI for CPI mode). The corresponding DATAx_POSITION bit must be set to 0x0 for the lane in GPI mode. Note: The settings differ when using CSIPHY1/CSIPHY2 and CCP2. See Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver.	RW	0x0
3	CLOCK_POL	±differential pin order of CLOCK lane. 0x0: ± pin order 0x1: ± pin order	RW	0

Bits	Field Name	Description	Type	Reset
2:0	CLOCK_POSITION	<p>Position and order of the CLOCK lane. The clock lane is always present.</p> <p>0x0: Not used/connected</p> <p>0x1: Clock lane is at position 1.</p> <p>0x2: Clock lane is at position 2.</p> <p>0x3: Clock lane is at position 3.</p> <p>0x5: Clock lane is at position 2 (using CSIPHY1) or 1 (using CSIPHY2). This setting is valid for CCP2 receiver mode only.</p> <p>Note: The settings differ when using CSIPHY1/CSIPHY2 and CCP2. See Section 6.5.2.2, Camera ISP CSIPHY Initialization for Work With CSI1/CCP2B Receiver.</p>	RW	0x0

Table 6-665. CSI2_TIMING

Address Offset	0x0000 006C		
Physical Address	See Table 6-638	Instance	See Table 6-80
Description	TIMING REGISTER This register controls the CSI2 RECEIVER module. This register shall not be modified while CSI2_CTRL.IF_EN is set to '1'. It is used to indicate the number of L3 cycles for the Stop State monitoring.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED												FORCE_RX_MODE_IO1	STOP_STATE_X16_IO1	STOP_STATE_X4_IO1	STOP_STATE_COUNTER_IO1																

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0
15	FORCE_RX_MODE_IO1	Control of ForceRxMode signal 0x0: De-assertion of ForceRxMode. The HW reset the bit at the end of the Force RX Mode assertion. The SW can reset the bit in order to stop the assertion of the ForceRXMode signal prior to the completion of the period. 0x1: Assertion of ForceRxMode	RW	0
14	STOP_STATE_X16_IO1	Multiplication factor for the number of L3 cycles defined in STOP_STATE_COUNTER_IO1 bit-field 0x0: The number of L3 cycles defined in STOP_STATE_COUNTER_IO1 is multiplied by 1x 0x1: The number of L3 cycles defined in STOP_STATE_COUNTER_IO1 is multiplied by 16x	RW	1
13	STOP_STATE_X4_IO1	Multiplication factor for the number of L3 cycles defined in STOP_STATE_COUNTER_IO1 bit-field 0x0: The number of L3 cycles defined in STOP_STATE_COUNTER_IO1 is multiplied by 1x 0x1: The number of L3 cycles defined in STOP_STATE_COUNTER_IO1 is multiplied by 4x	RW	1
12:0	STOP_STATE_COUNTER_IO1	Stop State counter for monitoring. It indicates the number of L3 to monitor for Stop State before de-asserting ForceRxMode (Complex I/O #1). The value is from 0 to 8191.	RW	0x1FFF

Address Offset	0x0000 0070 + (x * 0x20)	Index	x = 0 to 7
Physical Address	See Table 6-638	Instance	See Table 6-80
Description	CONTROL REGISTER - Context This register controls the Context. This register is shadowed: modifications are taken into account after the next FSC sync code.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
BYTESWAP	GENERIC	RESERVED			TRANSCODE				FEC_NUMBER								COUNT								EOF_EN	EOL_EN	CS_EN	COUNT_UNLOCK	PING_PONG	VP_FORCE	LINE_MODULO	CTX_EN

Bits	Field Name	Description	Type	Reset
31	BYTESWAP	Allows swapping bytes two by two in the payload data. It doesn't affect - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the Interconnect port and/or video port 0x0: Disabled 0x1: Enabled	RW	0
30	GENERIC	Enables the generic mode. 0x0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 0x1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored.	RW	0
29:28	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0
27:24	TRANSCODE	Enables image transcoding. When this features is enabled: - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register 0x0: Feature disabled. 0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data 0x3: Outputs ALAW compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data. 0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data 0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data 0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data 0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data 0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data 0x9: Outputs uncompressed RAW14 data.	RW	0x0
23:16	FEC_NUMBER	Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory. (shall be used only in interlace mode, otherwise set to '1')	RW	0x01

Bits	Field Name	Description	Type	Reset
15:8	COUNT	<p>Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to '0'.</p> <p>Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same Interconnect write access , the bit-field COUNT_UNLOCK shall be written in addition to COUNT bit-field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value."</p> <p>0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire.</p>	RW	0x00
7	EOF_EN	<p>Indicates if the end of frame signal shall be asserted at the end of the line.</p> <p>Read 0x0: The end of frame signal is not asserted at the end of each frame. Read 0x1: The end of frame signal is asserted at the end of each frame.</p>	RW	0
6	EOL_EN	<p>Indicates if the end of line signal shall be asserted at the end of the line.</p> <p>Read 0x0: The end of line signal is not asserted at the end of each frame. Read 0x1: The end of line signal is asserted at the end of each frame.</p>	RW	0
5	CS_EN	<p>Enables the checksum check for the received payload (long packet only).</p> <p>0x0: Disabled 0x1: Enabled</p>	RW	0
4	COUNT_UNLOCK	<p>Unlock writes to the COUNT bit field.</p> <p>Write 0x0: COUNT bit field is locked. Writes have no effect Write 0x1: COUNT bit field is unlocked. Writes are possible.</p>	W	0
3	PING_PONG	<p>Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame.</p> <p>This bit field toggles after every FEC_NUMBER FEC sync code received for the current context.</p> <p>Read 0x0: PING buffer Read 0x1: PONG buffer</p>	R	1
2	VP_FORCE	<p>Forces sending of the data to both VPORT and Interconnect.</p> <p>Only applies to formats that existing in 2 versions: - one sending data to Interconnect port only - one sending data to VPORTonly (tagged with the +VP extension) The format version sending data only to Interconnect should be choosen.</p> <p>0x0: Disabled 0x1: Enabled</p>	RW	0
1	LINE_MODULO	<p>Line modulo configuration</p> <p>0x0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 0x1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame)</p>	RW	0

Bits	Field Name	Description	Type	Reset
0	CTX_EN	Enables the Context 0x0: Disabled 0x1: Enabled	RW	0

Address Offset	0x0000 0078 + (x * 0x20)	Index	x = 0 to 7
Physical Address	See Table 6-638	Instance	See Table 6-80
Description	<p>DATA MEM ADDRESS OFFSET REGISTER - Context</p> <p>This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both CSI2_CT_x_DAT_PING_ADDR and CSI2_CT_x_DAT_PONG_ADDR.</p> <p>For example, it enables to perform 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data shall have the same data format.</p> <p>Note that the 5 LSBs are ignored: the offset shall be a multiple of 32 bytes.</p> <p>This register is shadowed: modifications are taken into account after the next FSC sync code. Only full 32-bit values shall be written.</p>		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								OFST										RESERVED													

Bits	Field Name	Description	Type	Reset
31:17	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x0000
16:5	OFST	Line offset programmed in bytes (signed value 2's complement). If OFST = 0, the data is written contiguously in memory. Otherwise, OFST sets the destination offset between the first pixel of the previous line and the first pixel of the current line.	RW	0x000
4:0	RESERVED	Write 0s for future compatibility. Read returns 0.	R	0x00

Display Subsystem

This chapter describes the Display Subsystem for the device.

NOTE: This document is strictly for wireless/cellular software developers using AM/DM37x application processors, which are not available for the broad market through authorized distributors.

NOTE: This chapter contains information that is ©2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

All rights reserved. This material is reprinted with the permission of the MIPI Alliance, Inc. No part(s) of this document may be disclosed, reproduced or used for any purpose other than as needed to support the use of the products of TI.

See [Device 37xx MIPI Disclaimer](#) for details.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5](#), *AM/DM37x Family* and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

7.1 Display Subsystem Overview	1549
7.2 Display Subsystem Environment	1554
7.3 Display Subsystem Integration	1606
7.4 Display Subsystem Functional Description	1623
7.5 Display Subsystem Basic Programming Model	1698
7.6 Display Subsystem Use Cases and Tips	1770
7.7 Display Subsystem Register Manual	1805

7.1 Display Subsystem Overview

The display subsystem provides the logic to display a video frame from the memory frame buffer (either SDRAM or SRAM) on a liquid-crystal display (LCD) panel or a TV set. The display subsystem integrates the following elements:

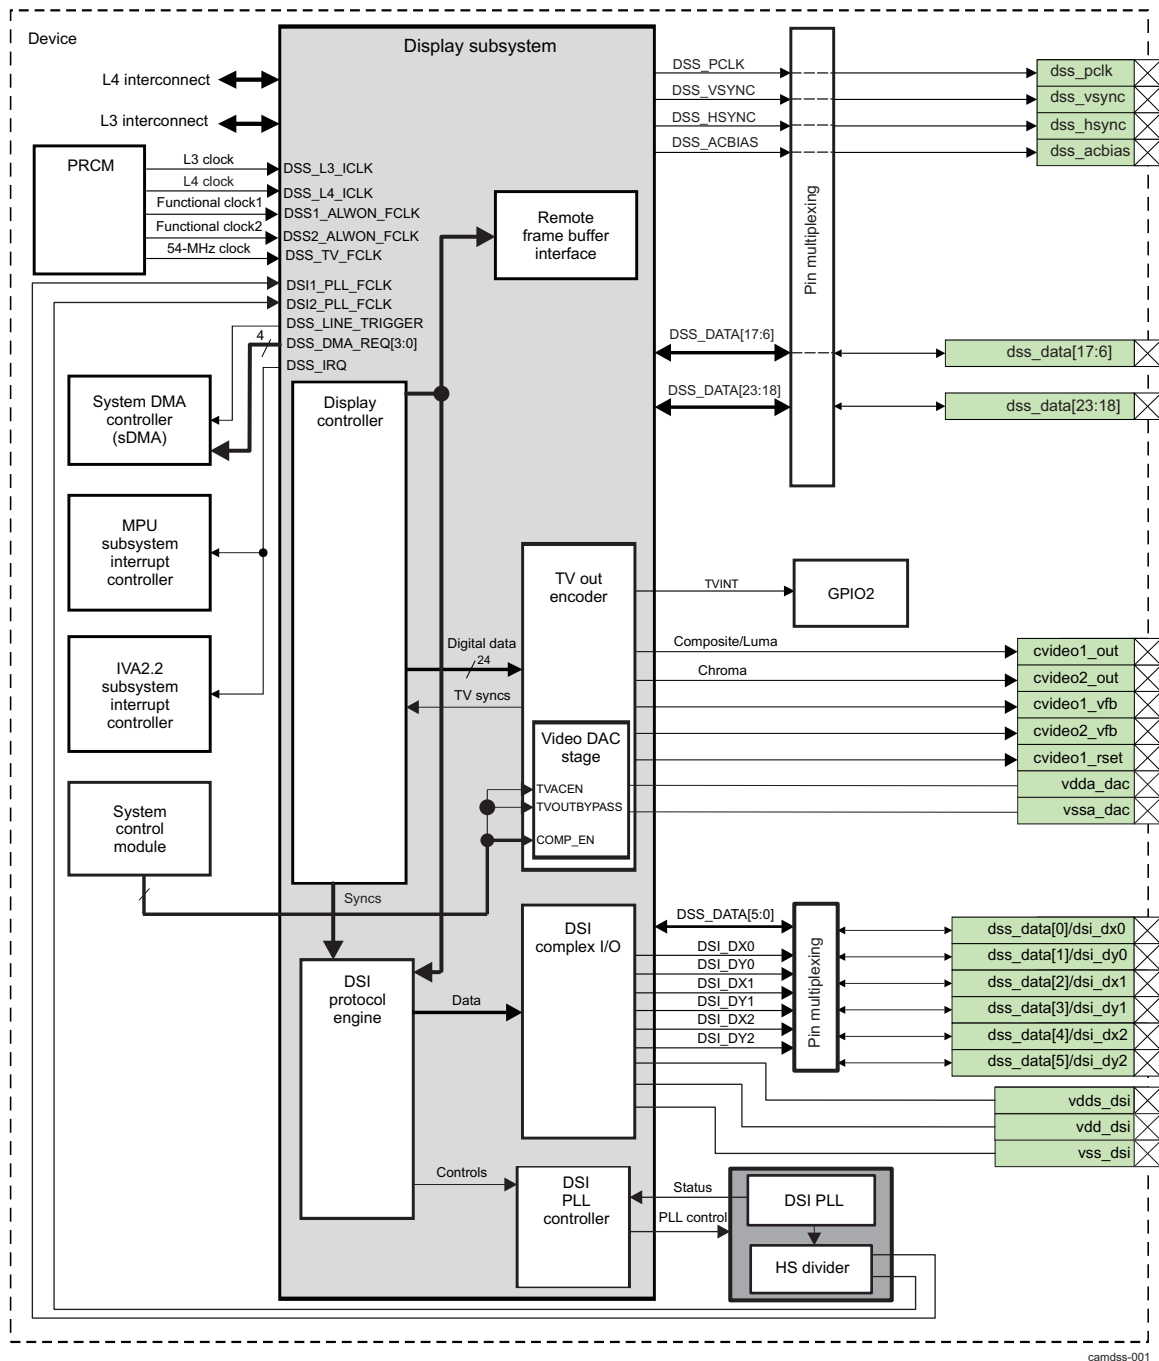

- Display controller (DISPC) module
- Remote frame buffer interface (RFBI) module
- Display serial interface (DSI) complex I/O module and a DSI protocol engine
- DSI PLL controller that drives a DSI PLL and high-speed (HS) divider.
- NTSC/PAL video encoder

The display controller and the DSI protocol engine are connected to the L3 and L4 interconnect; the RFBI and the TV out encoder modules are connected to the L4 interconnect.

NOTE: The DSI complex I/O module, and the DSI PLL controller are not connected to an L3 or L4 interconnect. Specific display subsystem registers manage their programmable features.

[Figure 7-1](#) shows a block diagram of the display subsystem.

Figure 7-1. Display Subsystem Highlight

NOTE: For more information about connecting the LOCK, RECAL, and TVINT signals through the GPIO2 and GPIO3 modules, see [Chapter 25, GPIO](#).

The display subsystem includes the following main features:

- Display controller
 - Display modes
 - Programmable pixel display modes (1, 2, 4, 8, 12, 16, and 24 bits-per-pixel [BPP] modes)
 - Programmable display size supported:

- XGA - 1024 x 768 VESA timings at 60 fps (pixel clock = 63.5 MHz)
- WXGA - 1280 x 800 VESA timings at 59.91 fps (pixel clock = 71 MHz)
- SXGA+ - 1400 x 1050 direct drive of LCD with minimal blanking at 50 fps (pixel clock = 75 MHz)
- HD 720p - 1280 x 720 at 60 fps (pixel clock = 74.25 MHz)
- 256 x 24-bit entries palette in red, green, and blue (RGB)
- Programmable pixel rate up to 75 MHz

NOTE: The panel size is programmable and can be any width that is a multiple of 8 pixels (line length) in the range [1:2048] pixels (in the case of the RFBI mode, the minimum transfer size is a byte). The maximum resolution is 2048 (lines) x 2048 (pixels).

- Display support
 - Four types of displays are supported: Passive (super-twist nematic [STN]) and active (thin-film transistor [TFT]) colors, passive (STN), and active (TFT) monochromes.
 - 4-/8-bit monochrome passive matrix panel interface support (15 grayscale levels supported using dithering block)
 - 8-bit color passive matrix panel interface support (3375 colors supported for a color panel using dithering block)
 - 12-/16-/18-/24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
 - Remote frame buffer support through the RFBI module
 - Partial display through the RFBI module
 - Second 24-bit digital output
 - Multiple-cycle output format on 8-/9-/12-/16-bit interface time division multiplexing (TDM)
 - HDMI through external bridge
- Signal processing
 - Overlay support for graphics (ARGB, RGBA, RGB, or Color Look-Up Table (CLUT)) and video1 (YCbCr 4:2:2, RGB), video2 (YCbCr 4:2:2, or ARGB, RGBA, RGB)
 - Programmable video resizer independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4), maximum input width of 1024 pixels in 5-tap mode, and 2048 pixels in 3-tap configurations; no limitation on input height
 - Rotation 90-, 180-, and 270-degrees with DISPC DMA engine
 - Transparency color key (source and destination)
 - Synchronized buffer update
 - Programmable video color space conversion YCbCr 4:2:2 into RGB
 - Hardware cursor
 - Gamma curve support on LCD output
 - Multiple-buffer support
 - Mirroring support
 - Programmable color phase rotation (CPR)
 - Alpha blending support (no rescaling in ARGB or RGBA formats), with pre-multiplied alpha control
- Advanced
 - Self-refresh using the DMA FIFO
 - Arbitration between high/low priority (graphics video1 and video2)
 - FIFO handcheck in STALL mode
- Power modes: Low-power saving modes
- RFBI (MIPI® DBI protocol)

- Access to remote frame buffer (RFB) direct microprocessor unit (MPU) interface
 - Sends commands to the RFB panel through the L4 interconnect
 - Sends data, received from the display controller or from the MPU through the DISPC pixel data bus, to the RFB panel
 - Reads data/status from the RFB to the L4 interconnect
- RFB interface
 - 8-/9-/12-/16-bit 8086-series parallel interface
 - Two programmable configurations for two devices connected to the RFBI module
- Data formats
 - Programmable pixel modes (12-/16-/18-/24-BPP modes in RGB format)
 - Programmable output formats on one/multiple cycles per pixel (data from the display controller and from the L4 interconnect)
- Interconnect/FIFO
 - One slave port with DMA request and interconnect FIFO of 24x32-bit depth (for write access to [DSS.RFBI_DATA](#) register only)
 - One video port FIFO of 8 x 24-bit depth receiving data from the display controller
- MIPI DSI
 - Transfer pixels and data received on the video port or L4 interconnect to the display through the DSI DSI_PHY
 - The maximum resolution supported on the video port is SVGA at 60 fps with 24-bit pixels (maximum pixel clock of 48 MHz) for low voltage, and WXGA at 60 fps with 24-bit pixels (maximum pixel clock of 86.5 MHz) for nominal voltage..
 - Supports video mode and command mode
 - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
 - Supports up to two data-configurable lanes, in addition to the clock signaling (minimum of one data link and maximum of two, depending on speed, signal integrity requirements, and number of displays)
 - Maximum data rate of up to 900 Mbps per data pair
 - Data splitter for 2-data lane configuration
 - Error-correction code (ECC) and check-sum generation
 - Burst support for the video mode
 - RGB16, RGB18 packed and nonpacked, and RGB24 formats supported for video mode
 - Serial configuration port (SCP) for the DSI_PHY complex I/O and DSI PLL
 - Connection to the DSI_PHY complex I/O through PPI
 - Data interleaving support for one synchronous stream (video mode) from the display controller and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
 - Data interleaving supports up to four interleaved asynchronous streams (command mode) from the interconnect or video port when there is no video mode
 - MIPI DCS support (transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral)
 - Supports selection between low-power state and HS mode between HS packet transfers
 - Generic data type (DT) support

NOTE: The DSI pins are multiplexed with LCD parallel outputs.

- Video encoder
 - NTSC/PAL encoder outputs with the following standards:
 - NTSC-J, M

- PAL-B, D, G, H, I
- PAL-M
- CGMS-A as described in the CEA-608-x Standard.
- Input data interface compatible with the following protocols:
 - 24-bit input bus compatible with external sync
 - RGB 4:4:4
- Dual output data 10-bit interface for two internal digital-to-analog converters (DACs) that support:
 - Composite video (CVBS)
 - Separate video (S-video)
- TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
- Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
- Programmable horizontal sync, vertical timing, and waveforms
- Programmable subcarrier frequency and SCH
- Internal test pattern generation (color bar, flat field, color burst)
- 2x/4x oversampling
- Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

CAUTION

In square pixel mode, an external clock generator is required to provide sampling frequencies.

- TV detection gating pulse generation

7.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

7.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

[Table 7-1](#) provides more details on the supported interfaces to LCD panels, and the respective pad and signal configurations.

Table 7-1. LCD Interface Signals and Configurations

Pad names at device level boundary.	Pads Property	Pads and Signals Configuration				Possible Operational Interfaces

sys_boot0	System control module				DISPC_DATA_L CD18		DISPC_DATA_L CD [18-23]				
sys_boot1					DISPC_DATA_L CD19						
sys_boot3					DISPC_DATA_L CD20						
sys_boot4					DISPC_DATA_L CD21						
sys_boot5					DISPC_DATA_L CD22						
sys_boot6					DISPC_DATA_L CD23						

The DISPC_DATA_LCD[23:18] data is additionally multiplexed on the sys_boot device pads to allow simultaneous availability of the DSI interface and the complete parallel 24-bit DSS interface.

NOTE: The DISPC_DATA_LCD[5:0] data multiplexed with the DSI signals on dss_data[5:0] pads is limited to up to 60 MHz pixel clock frequency. If the parallel 18/24-bit interface in bypass mode with a pixel clock above 60 MHz is required, the DISPC_DATA_LCD[5:0] multiplexed on dss_data[23:18] pads, and DISPC_DATA_LCD[23:18] multiplexed on sys_boot pads must be used.

NOTE: [Table 7-1](#) shows only the DSS capabilities of supporting simultaneous and sequential LCD interfaces due to the additional signal multiplexing, without describing explicitly all possible configurations.

For more information on signals multiplexing, see [Chapter 13, System Control Module](#). The parallel interface connectivity is detailed in [Section 7.2.1.1, Parallel Interface](#). For more details on the serial interface, see [Section 7.2.1.2, DSI Serial Interface](#).

7.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI 2.0 protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI 1.0 protocol

The DSS.DISPC_CONTROL[16:15] GPOUT[1:0] bits control selection of the display subsystem modules (see [Table 7-2](#)).

Table 7-2. I/O Pad Mode Selection

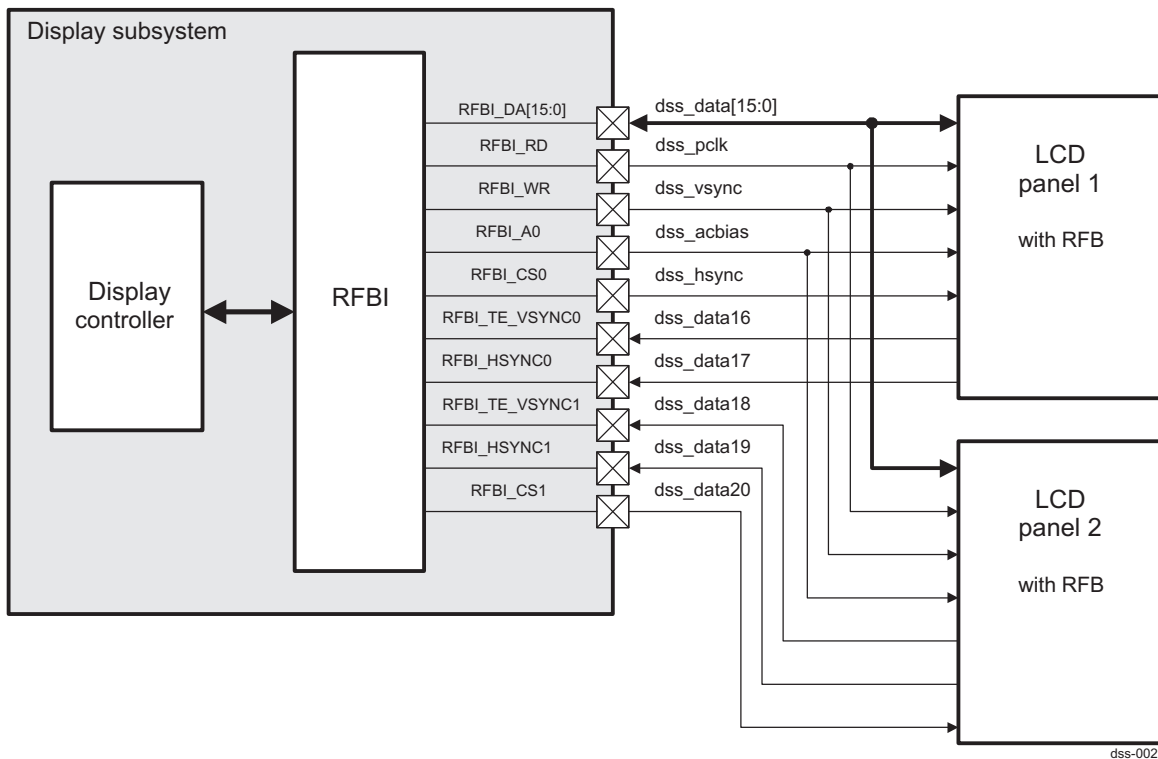

DSS.DISPC_CONTROL[16] GPOUT1	DSS.DISPC_CONTROL[15] GPOUT0	Mode
0	0	Reset
0	1	RFBI mode
1	0	Invalid
1	1	Bypass mode

The RFB of the LCD panel is connected directly to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from the memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

7.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

[Figure 7-2](#) shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

Figure 7-2. LCD Support Parallel Interface (RFBI Mode)

NOTE: Configure the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 7-3 describes the interface signals to/from the LCD panel in RFBI mode.

Table 7-3. LCD Interface Signals (RFBI Mode)

Signal Name	Type ⁽¹⁾	Description
RFBI_DA[15:0]	I/O	RFBI I/O data
RFBI_RD	O	Read access signal
RFBI_WR	O	Write access signal
RFBI_A0	O	Command/data selection signal
RFBI_CS0	O	Chip-select (CS) signal for LCD 1
RFBI_CS1	O	CS signal for LCD 2
RFBI_TE_VSYNC0	I	Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1)
RFBI_HSYNC0	I	HSYNC from LCD panel 1
RFBI_TE_VSYNC1	I	TE synchronization signal (TE or VSYNC for LCD panel 2)
RFBI_HSYNC1	I	HSYNC from LCD panel 2

⁽¹⁾ I = Input, O = Output

- RFBI_DA[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.
Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel module. RFBI_DA is multiplexed at the chip-level boundary with dss_data [15:0].
- RFBI_RD: This is the read-enable signal used to indicate when a read from the embedded memory in the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle

time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with `dss_pclk`. The read is used to get status/data information from the LCD panel.

- **RFBI_WR:** The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with `dss_vsync`.
- **RFBI_A0:** The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with `dss_acbias`.
- **RFBI_CSx:** The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed (x = 0 for LCD panel 1; x = 1 for LCD panel 2). CS0 is multiplexed at the chip-level boundary with `dss_hsync`, and CS1 is multiplexed at the chip-level boundary with `dss_data[20]`.
- **RFBI_TE_VSYNCx:** Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI_TE_VSYNCx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.

To select the trigger mode, configure the DSS.[RFBI_CONFIGi\[3:2\]](#) TRIGGERMODE bit field (0x0: Internal trigger mode with the DSS.[RFBI_CONTROL\[4\]](#) ITE bit, 0x1: External trigger mode with the TE signal RFBI_TE_VSYNCx, 0x2: External trigger mode with the RFBI_TE_VSYNCx, and RFBI_HSYNCx signals with the programmable line counter).

These signals are multiplexed at the chip-level boundary with `dss_data[16]` (RFBI_TE_VSYNC0) and `dss_data[18]` (RFBI_TE_VSYNC1) (LCD panel 1: x = 0; LCD panel 2: x = 1).

- **RFBI_HSYNCx:** The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with `dss_data[17]` (RFBI_HSYNC0) and `dss_data[19]` (RFBI_HSYNC1) (LCD panel 1: x = 0; LCD panel 2: x = 1).

7.2.1.1.1.1 Description of the TE Pulse Signal

The externally-generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see [Figure 7-3](#)). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

Figure 7-3. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.[RFBI_VSYNC_WIDTH](#) register.

HSYNC is detected based on the minimum pulse width defined by the DSS.[RFBI_HSYNC_WIDTH](#) register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI_TE signal or use a bit field in the RFBI registers to start data capture.

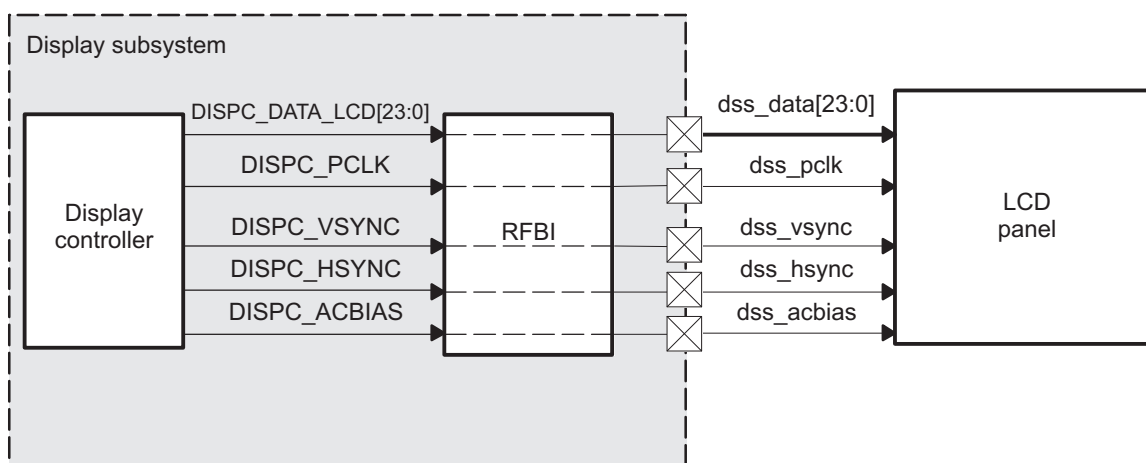

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDED signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

7.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 7-4 shows the LCD support parallel interface in bypass mode.

Figure 7-4. LCD Support Parallel Interface (Bypass Mode)

dss-004

Table 7-4 describes the interface signals to/from the LCD panel in bypass mode.

Table 7-4. LCD Interface Signals (Bypass Mode)

Signal Name	Type ⁽¹⁾	Description
DISPC_DATA_LCD[23:0]	O	LCD data from the display controller module
DISPC_PCLK	O	Pixel CLK from the display controller module
DISPC_VSYNC	O	VSYNC from the display controller module
DISPC_HSYNC	O	HSYNC from the display controller module
DISPC_ACBIAS	O	ACBIAS from the display controller module

⁽¹⁾ I = Input, O = Output, I/O = Input/Output

- DISPC_DATA_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC_DATA_LCD is connected at the chip-level boundary with dss_data[23:0].
- DISPC_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss_pclk.
- DISPC_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed with dss_vsync at the chip-level boundary.
- DISPC_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal is multiplexed on the chip-level boundary with dss_hsync.
- DISPC_ACBIAS: Uses the ac-bias signal from the display controller.

- In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
- In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with dss_acbias.

7.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 7-5 through Figure 7-11 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 7-5 lists the number of displayed pixels per pixel clock cycle based on the type of display panel.

Table 7-5. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type

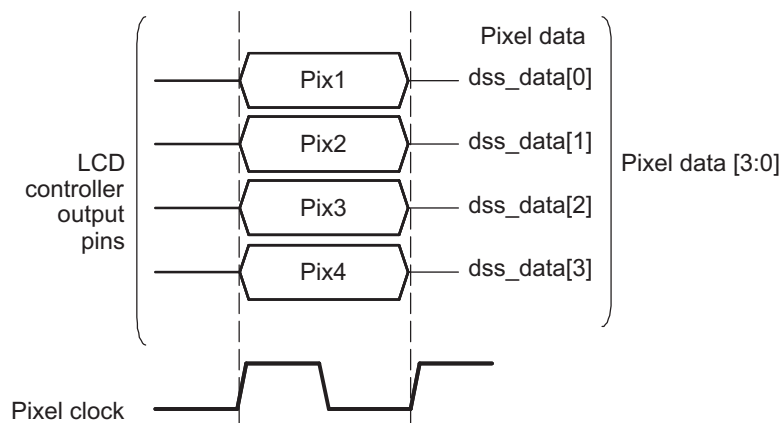

Display Panel	Number of Displayed Pixels per Pixel Clock Cycle
Monochrome 4-bit	4
Monochrome 8-bit	8
Passive matrix color	8/3
Active matrix	1

- Passive matrix technology, Monochrome mode

Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

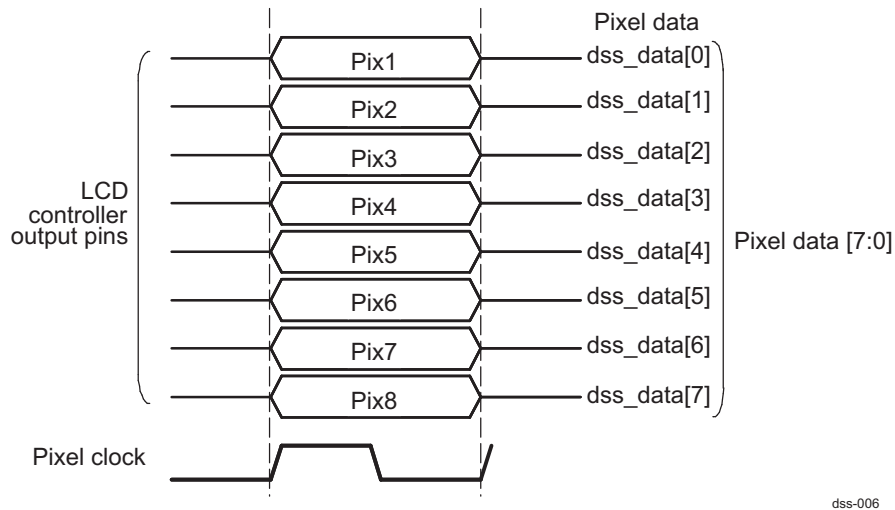

Figure 7-5 and Figure 7-6 show 4- and 8-bit monochrome displays, respectively.

Figure 7-5. LCD Pixel Data Monochrome4 Passive Matrix

dss-005

Figure 7-6. LCD Pixel Data Monochrome8 Passive Matrix

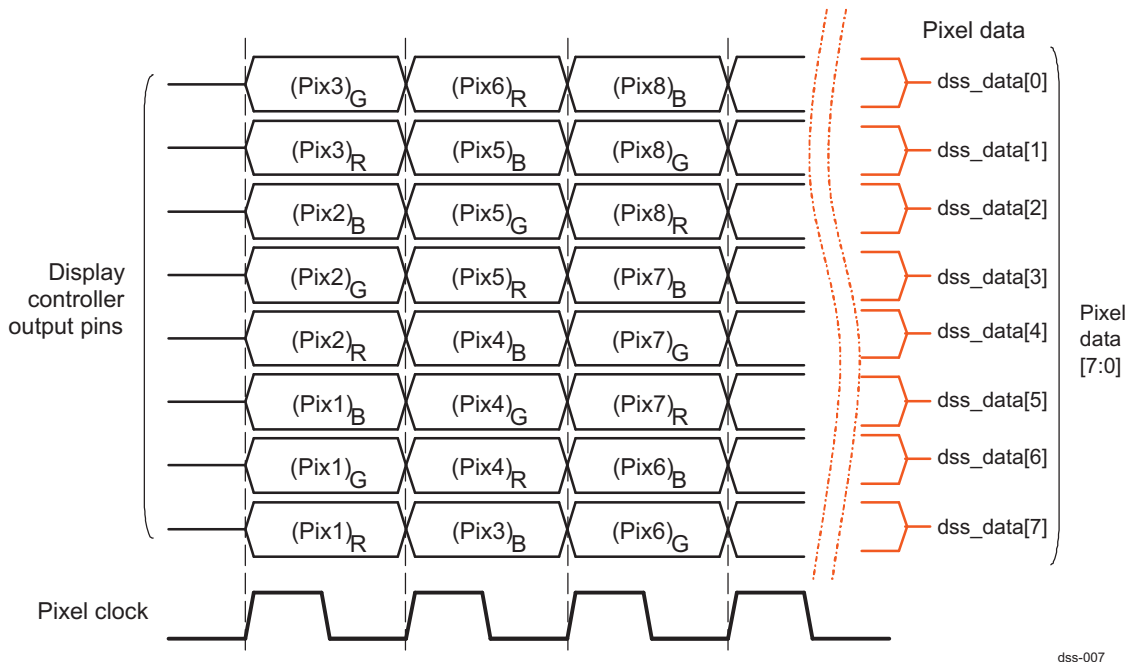

dss-006

- Passive matrix technology, color mode
Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).

Figure 7-7 shows an 8-bit color passive matrix display.

Figure 7-7. LCD Pixel Data Color Passive Matrix

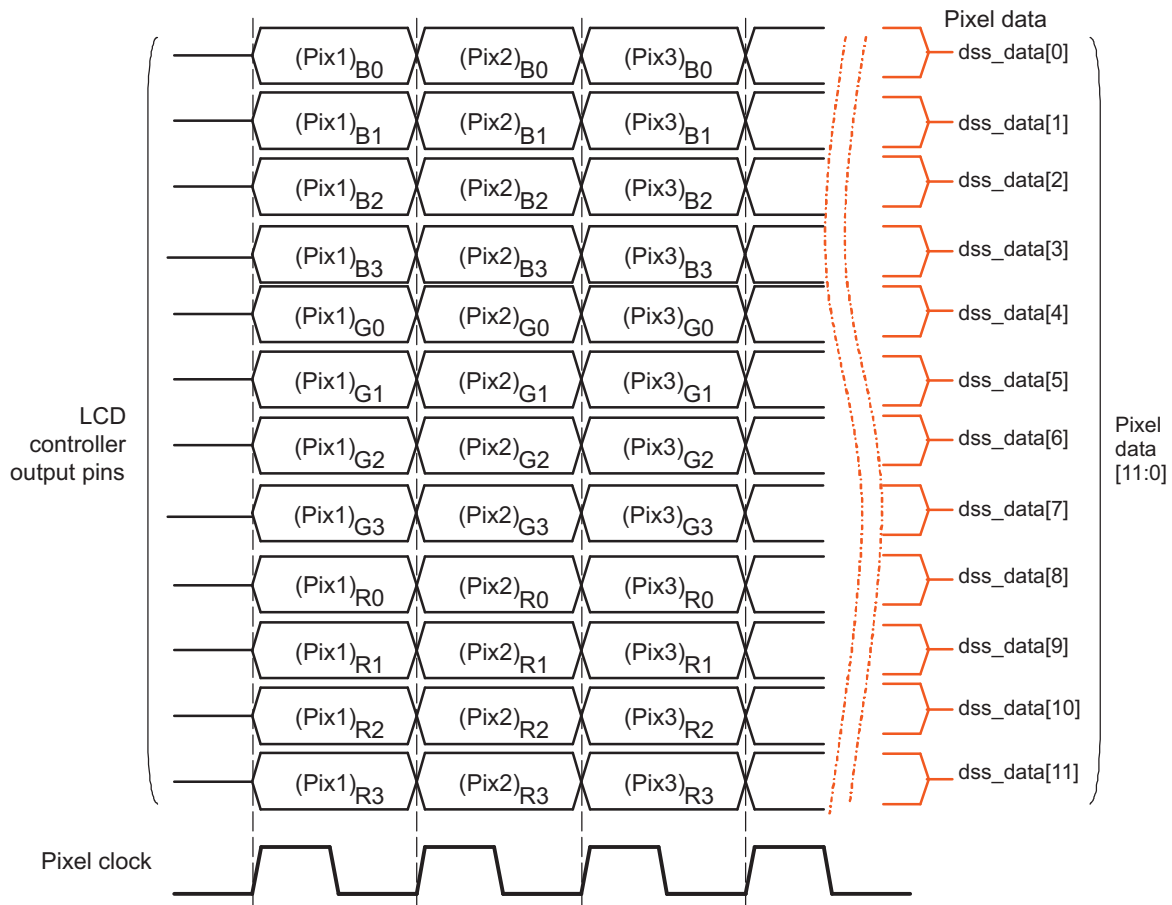

dss-007

- Active matrix technology
Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.

Figure 7-8 through Figure 7-11 show 12-, 16-, 18-, and 24-active matrix displays, respectively.

Figure 7-8. LCD Pixel Data Color12 Active Matrix

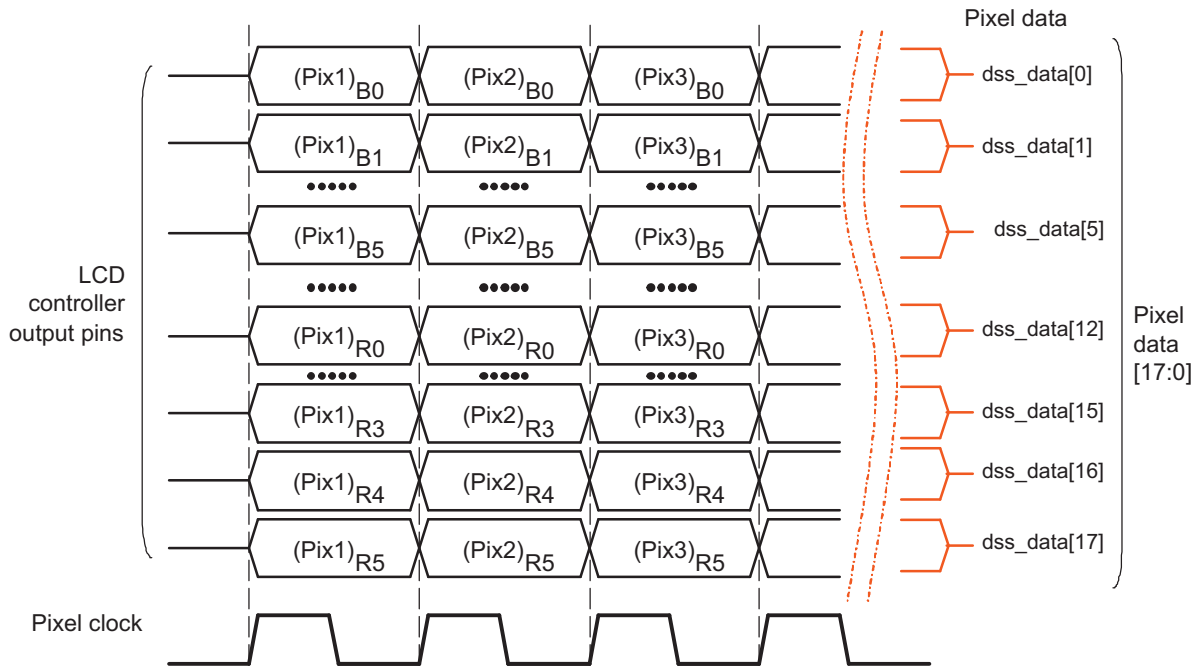

dss-008

Figure 7-11. LCD Pixel Data Color24 Active Matrix

dss-011

7.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
 - Stall signal

The stall signal is used in RFBI and DSI modes. In the case of RFBI mode, it is used to indicate when the display controller must stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data must be outputted by the display controller.

Figure 7-12. RFBI Data Stall Signal Diagram

dss-134

To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the `DSS.DISPC_CONFIG[16]` FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature must be enabled only when the STALL mode is used (`DSS.DISPC_CONTROL[11]` STALLMODE bit set to 1).

When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow cannot occur for the pipelines associated with the LCD output in RFBI mode. [Figure 7-13](#) details the RFBI data stall with FIFO handcheck mode activated.

Figure 7-13. RFBI Data Stall Signal Diagram With Handcheck

– RFBI timing diagrams

Table 7-6 lists the programmable timing fields. Figure 7-14 through Figure 7-16 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

Table 7-6. Programmable Timing Fields in RFBI Mode

Timing Name	Register Field	Description
CSOnTime	DSS.RFBI_ONOFF_TIME[3:0] CSONTIME (with I = 0 or 1)	CS assertion time from start access time
CSOffTime	DSS.RFBI_ONOFF_TIME[9:4] CSOFFTIME (with I = 0 or 1)	CS deassertion time from start access time
WeCycleTime	DSS.RFBI_CYCLE_TIME[5:0] WECYCLETIME (with I = 0 or 1)	The time when A0 becomes valid until write cycle completion
WEOnTime	DSS_RFBI_ONOFF_TIME[13:10] WEONTIME (with I = 0 or 1)	WE assertion delay time from start access time
WEOffTime	DSS_RFBI_ONOFF_TIME[19:14] WEOFFTIME (with I = 0 or 1)	WE deassertion delay time from start access time
RECycleTime	DSS.RFBI_CYCLE_TIME[11:6] RECYCLETIME (with I = 0 or 1)	The time when A0 becomes valid until read cycle completion
REOnTime	DSS_RFBI_ONOFF_TIME[23:20] REONTIME (with I = 0 or 1)	RE assertion delay time from start access time
REOffTime	DSS.RFBI_ONOFF_TIME[29:24] REOFFTIME (with I = 0 or 1)	RE assertion delay time from start access time
CSPulseWidth	DSS.RFBI_CYCLE_TIME[17:12] CSPULSEWIDTH (with I = 0 or 1)	The time when write cycle time or read cycle time completes

Figure 7-14. Command Data Write

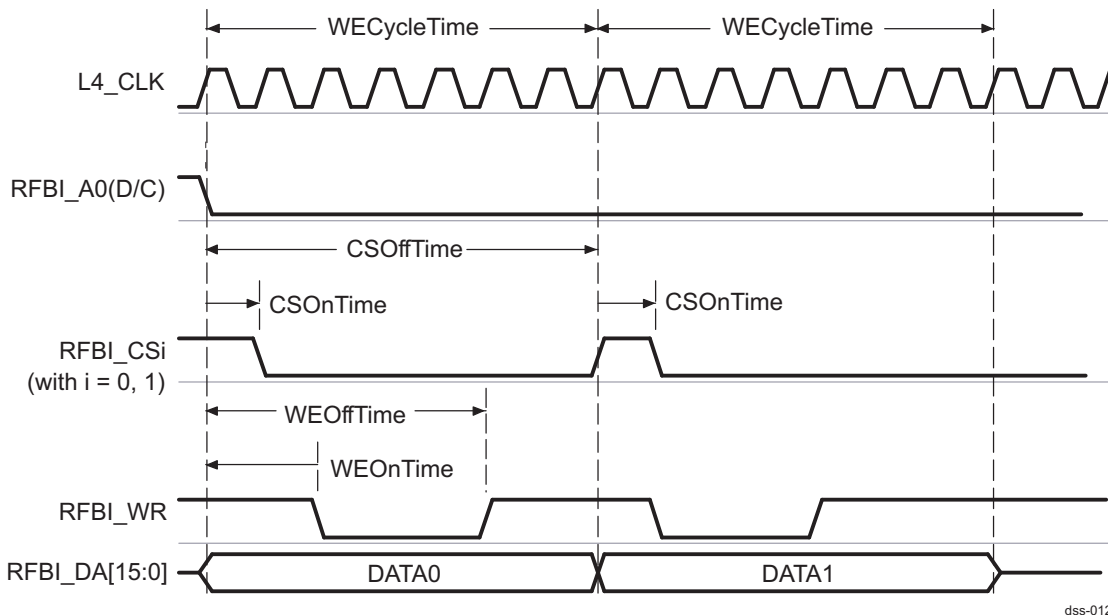

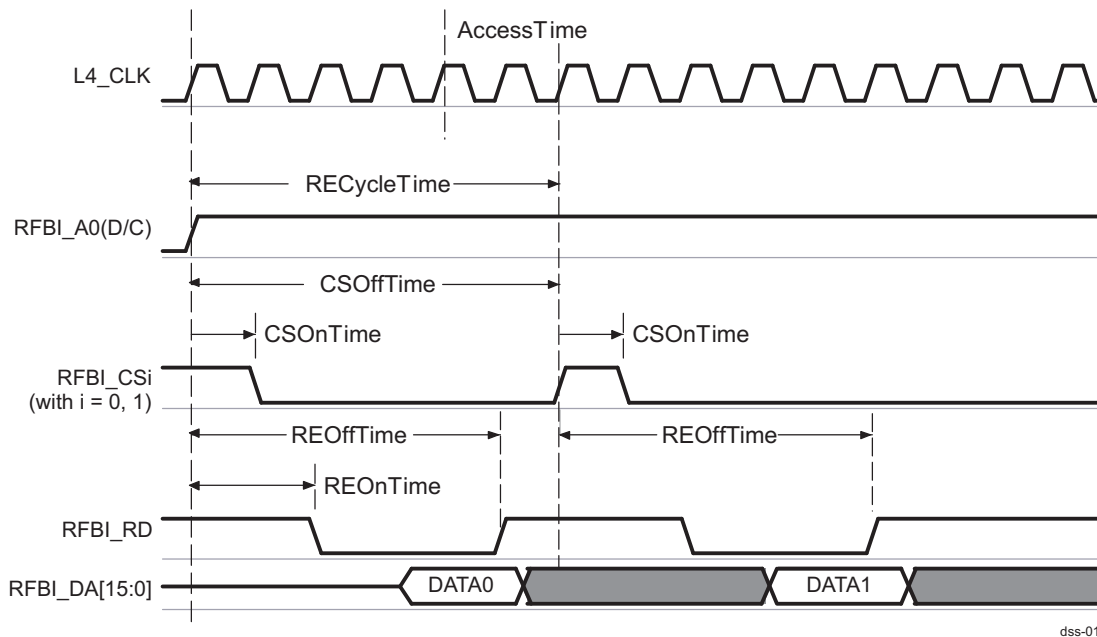

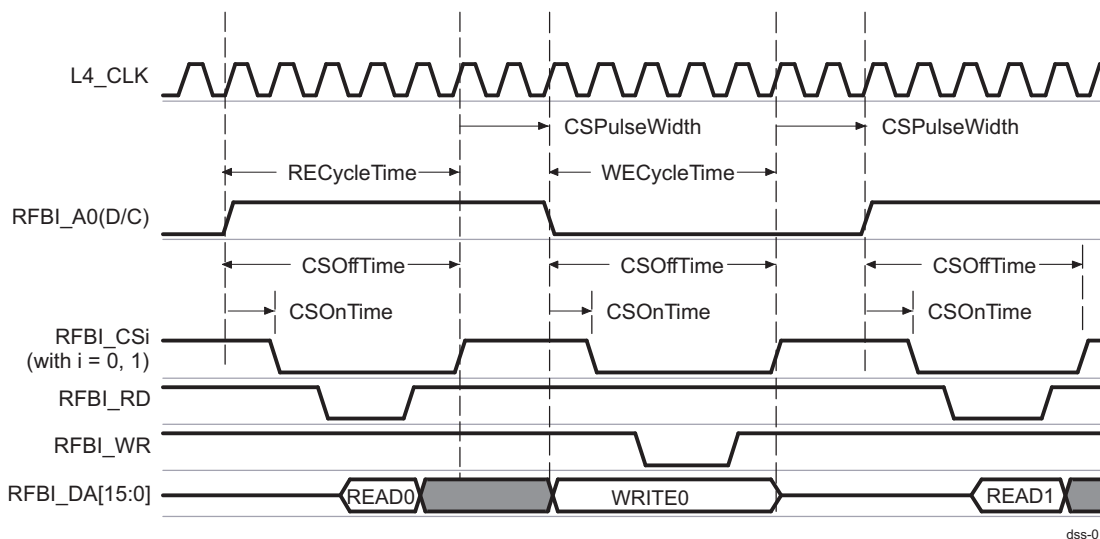

Figure 7-15. Display Data Read**Figure 7-16. Read to Write and Write to Read**

- Timing diagrams in bypass mode

[Figure 7-17](#) through [Figure 7-32](#) show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in [Table 7-7](#).

Table 7-7. Programmable Fields in Bypass Mode

Name	Register	Description
PPL	DSS.DISPC_SIZE_LCD[10:0] PPL bit field value + 1	Pixels per line (PPL)
LPP	DSS.DISPC_SIZE_LCD[26:16] LPP bit field value + 1	Lines per panel
HBP	DSS.DISPC_TIMING_H[31:20] HBP bit field value + 1	Horizontal back porch
HFP	DSS.DISPC_TIMING_H[19:8] HFP bit field value + 1	Horizontal front porch
HSW	DSS.DISPC_TIMING_H[7:0] HSW bit field value + 1	Horizontal synchronization pulse width

Table 7-7. Programmable Fields in Bypass Mode (continued)

Name	Register	Description
VBP	DSS.DISPC_TIMING_V[31:20] VBP bit field value	Vertical back porch
VFP	DSS.DISPC_TIMING_V[19:8] VFP bit field value	Vertical front porch
VSW	DSS.DISPC_TIMING_V[7:0] VSW bit field value + 1	Vertical synchronization pulse width
ONOFF	DSS.DISPC_POL_FREQ[17] ONOFF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock control
RF	DSS.DISPC_POL_FREQ[16] RF bit	DISPC_HSYNC and DISPC_VSYNC pixel clock edge control
IEO	DSS.DISPC_POL_FREQ[15] IEO bit	Invert DISPC_ACBIAS
IPC	DSS.DISPC_POL_FREQ[14] IPC bit	Invert DISPC_PCLK
IHS	DSS.DISPC_POL_FREQ[13] IHS bit	Invert DISPC_HSYNC
IVS	DSS.DISPC_POL_FREQ[12] IVS bit	Invert DISPC_VSYNC

- Active matrix timing configuration 1
 - DSS.DISPC_POL_FREQ[17] ONOFF bit = 0
 - DSS.DISPC_POL_FREQ[16] RF bit = 0
The DISPC_HSYNC and DISPC_VSYNC signals are driven on the opposite edge of DISPC_PCLK from the pixel data.
 - DSS.DISPC_POL_FREQ[15] IEO = 0
The DISPC_ACBIAS signal is active high.
 - DSS.DISPC_POL_FREQ[14] IPC = 0
The pixel data are driven on the rising edge of DISPC_PCLK.
 - DSS.DISPC_POL_FREQ[13] IHS = 0
The DISPC_HSYNC signal is active high.
 - DSS.DISPC_POL_FREQ[12] IVS = 0
The DISPC_VSYNC signal is active high.

7.2.1.2 DSI Serial Interface

Figure 7-33 shows a typical connection between the DSI modules and a compliant panel display.

Figure 7-33. Typical DSI Connection

dss-194

NOTE: The DSI pins are multiplexed in mode 1 with some LCD parallel pins. See [Chapter 13, System Control Module](#), for more details on pad multiplexing.

7.2.2 LCD Support With MIPI DSI 1.0 Protocol and Data Format

This section summarizes the MIPI® DSI1.0 protocol and data format.

NOTE: Copyright ©2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

7.2.2.1 Physical Layer

Table 7-8 lists the DSI interface I/O.

Table 7-8. I/O Description for DSI Serial Interface

Signal Name	I/O ⁽¹⁾	Description	Value at Reset
dsi_dx0	line 1	I/O	Serial data/clock input/output
dsi_dy0			
dsi_dx1	line 2	I/O	Serial data/clock input/output
dsi_dy1			
dsi_dx2	line 3	I/O	Serial data/clock input/output

⁽¹⁾ I/O = Input/Output

Table 7-8. I/O Description for DSI Serial Interface (continued)

Signal Name	I/O ⁽¹⁾	Description	Value at Reset
dsi_dy2			

NOTE: Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. All polarities are supported. The MIPI DSI 1.0 protocol requires at least one clock line and one data lane.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultra-low power state used between two transmissions
- Off mode: Lane is off.

7.2.2.1.1 Data/Clock Configuration

From the device point of view, the DSI interface consists of six input/output signals representing three differential signals: The serial clock and one or two serial data. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The DSI transmitter in the host sends the data in-quadrature with the DDR clock in high speed mode; otherwise, the clock is extracted from the received data in low-speed mode. The data is transmitted byte-wise least significant bit (LSB) first.
- The clock signal carries the DDR clock signal in high speed transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI_PHY into bytes.

Table 7-9 details all the DSI lanes configuration.

Table 7-9. DSI Lane Configuration

DSI DSI_PHY Lane Configuration	Data/Clock Lane Position			Description
	1	2	3	
Mode CLK + DATA1	CLK	DATA1	Not used	Single data lane
	CLK	Not used	DATA1	
	DATA1	CLK	Not used	
	Not used	CLK	DATA1	
	DATA1	Not used	CLK	
	Not used	DATA1	CLK	
Mode CLK + DATA1 + DATA2	CLK	DATA1	DATA2	Two data lanes
	CLK	DATA2	DATA1	
	DATA1	CLK	DATA2	
	DATA2	CLK	DATA1	
	DATA1	DATA2	CLK	
	DATA2	DATA1	CLK	

NOTE:

- The byte on Dn is sent before the byte on Dn+1, all the combinations of data and clock are supported through programming of the DSS.DSI_COMPLEXIO_CFG1 register. The CLOCK_POSITION and CLOCK_POL bit fields configure which lane transmits the clock and define its polarity. Four bit fields (DATA1_POSITION, DATA1_POL, DATA2_POSITION, and DATA2_POL) configure the data lanes and their polarity. The DATA2_POSITION bit field can be set to 0; in this case, only the data lane defined in the DATA1_POSITION bit field is used, and data is transmitted on only one clock lane and one data lane.
- The configuration of the DSI complex I/O (number of data lanes, position, differential order) must not be changed while DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is set to 1. For the hardware to recognize a new configuration of the complex I/O (done in DSS.DSI_COMPLEXIO_CFG1 register), it is recommended to follow this sequence: First set the DSS.DSI_CTRL[0] IF_EN bit to 1, next reset the DSS.DSI_CTRL[0] IF_EN to 0, then set DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE to 1, and finally, set again the DSS.DSI_CTRL[0] IF_EN bit to 1. If the sequence is not followed, the DSI complex I/O configuration is undetermined.
- Only DATA1 is bidirectional in command mode. The low-power received information is always sent by the display panel using DATA1. Since any lane of the DSI complex I/O can be configured as data lane DATA1, all lanes of the complex I/O are bidirectional

7.2.2.1.2 ULPS

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the DSI module.
- For data lane 1, no BTA should have been sent. The DSI module should have control of the bus.

The control of each lane is independently controlled by the DSS.DSI_COMPLEXIO_CFG2 register.

7.2.2.2 Video Port (VP) Interface

NOTE: The signals described in this section are internal and not bounded outside the device. This section aims at helping software users understand the internal connections between the display controller (DISPC) and the DSI protocol engine.

[Table 7-10](#) summarizes the video interface signals. This interface is used to connect the display controller to the DSI protocol engine to send real time data streams. Note that only the active matrix timings are supported by DSI protocol engine. The HSYNC/VSYNC/DE/DATA signals are driven on the rising or falling edge of the pixel clock (VP_PCLK).

Table 7-10. Video Interface for DSI Protocol Engine

Signal Name	Type ⁽¹⁾	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: Bits 0 to 23
VP_PCLK	I	Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP_CLK. The VP_PCLK is generated from VP_CLK through division. The clock ratio is defined in the DSS.DSI_CTRL[4] VP_CLK_RATIO bit and must be aligned with the configuration of the clock divisor in the display controller (DSS.DISPC_DIVISOR[7:0] PCD bit field).
VP_DE	I	Data enable

⁽¹⁾ I = Input, O = Output

Table 7-10. Video Interface for DSI Protocol Engine (continued)

Signal Name	Type ⁽¹⁾	Description
VP_STALL	O	The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated).
VP_CLK	I	Display controller internal clock. It is a free-running clock.

NOTE:

- The polarities of VP_HSYNC and VP_VSYNC are programmable by setting the DSS.DSI_CTRL register.
- The maximum frequency for VP_CLK is 173 MHz at nominal voltage, and 96 MHz at low voltage.
- Clocks VP_CLK and VP_PCLK can have the same frequency.
- The number of bits to be captured on the video port is defined in the DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.
- VP_DE is connected to the dss_acbias signal in the display controller, and its polarity can be controlled by setting the DISPC_POL_FREQ[15] IEO bit.

The data received on the video port can be stored into the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the display controller.
- There is no line buffer instantiated. If there is no line buffer, the burst mode, defined as frequency burst mode, cannot be used. Only the transparency burst mode is supported.

NOTE: The DSS.DSI_CTRL[13:12] LINE_BUFFER bit field defines the number of lines to be used for transferring data from the video port to the DSI link.

7.2.2.2.1 Video Port Used for Video Mode

If the video port is used for video mode, the VP_STALL is not used. [Table 7-11](#) lists the active signals on the video port.

Table 7-11. Video Interface in the Context of Video Mode

Signal Name	Type ⁽¹⁾	Description
VP_HSYNC	I	Horizontal sync signal
VP_VSYNC	I	Vertical sync signal
VP_DATA[23:0]	I	Parallel output data: bits 0 to 23
VP_PCLK	I	Pixel clock.
VP_DE	I	Data enable
VP_CLK	I	It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage, and 96 MHz at low voltage.

⁽¹⁾ I = Input, O = Output

Three video modes are available:

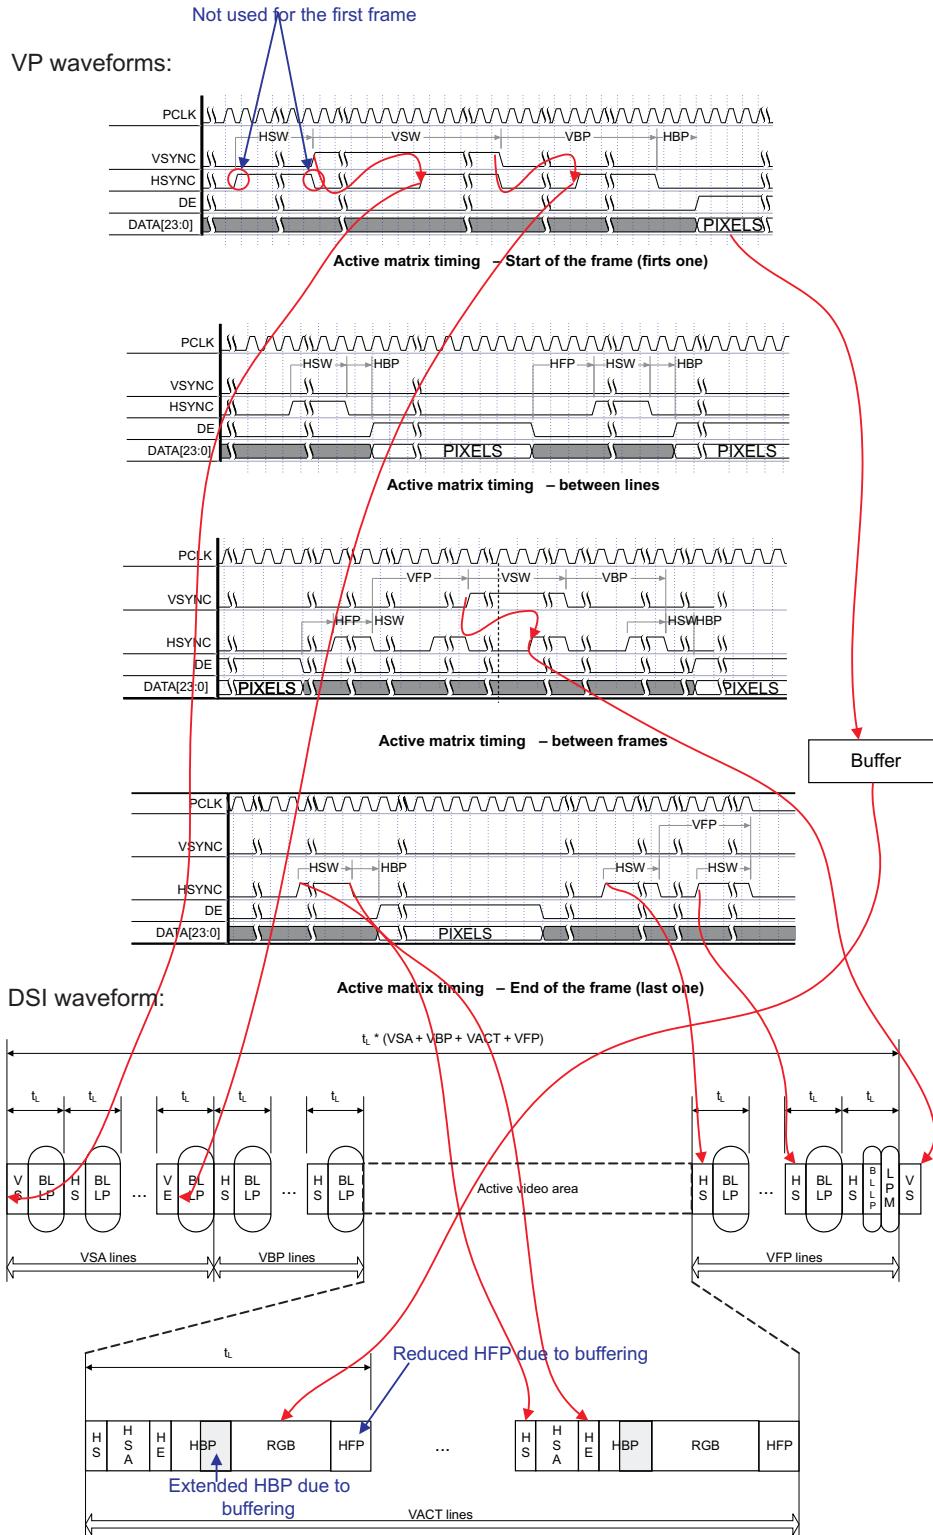

- No line buffer: The data received on the video port are directly output of the DSI port without buffering. The ration of VP_CLK and the DSI high-speed (HS) clock period must ensure identical throughput on the two ports (the two clocks must be generated using the same PLL; the subsystem must provide such configuration).
- One line buffer:
 - The data are first stored in the line buffer; once all the data for one line are received, the DSI protocol engine sends the whole line. The software must adjust timings to allow for the storage of all line data into the line buffer before sending to DSI outputs. The synchronization packets are never stored into the line buffer.

- Two line buffers:
 - One line is stored when the second line is output on the DSI port. It allows burst capability. While receiving the first line of the frame, there is no RGB packets sent because the line buffers are empty. To send the last line of the frame, a dummy line must be provided by the display controller to flush the line buffers. The synchronization packets are never stored into the line buffer.

NOTE: If more active lines are received on the video port than the number defined in the DSS.DSI_VM_TIMING3[15:0] VACT bit field, the extra lines are discarded by the DSI protocol engine. These lines are treated as blanking lines.

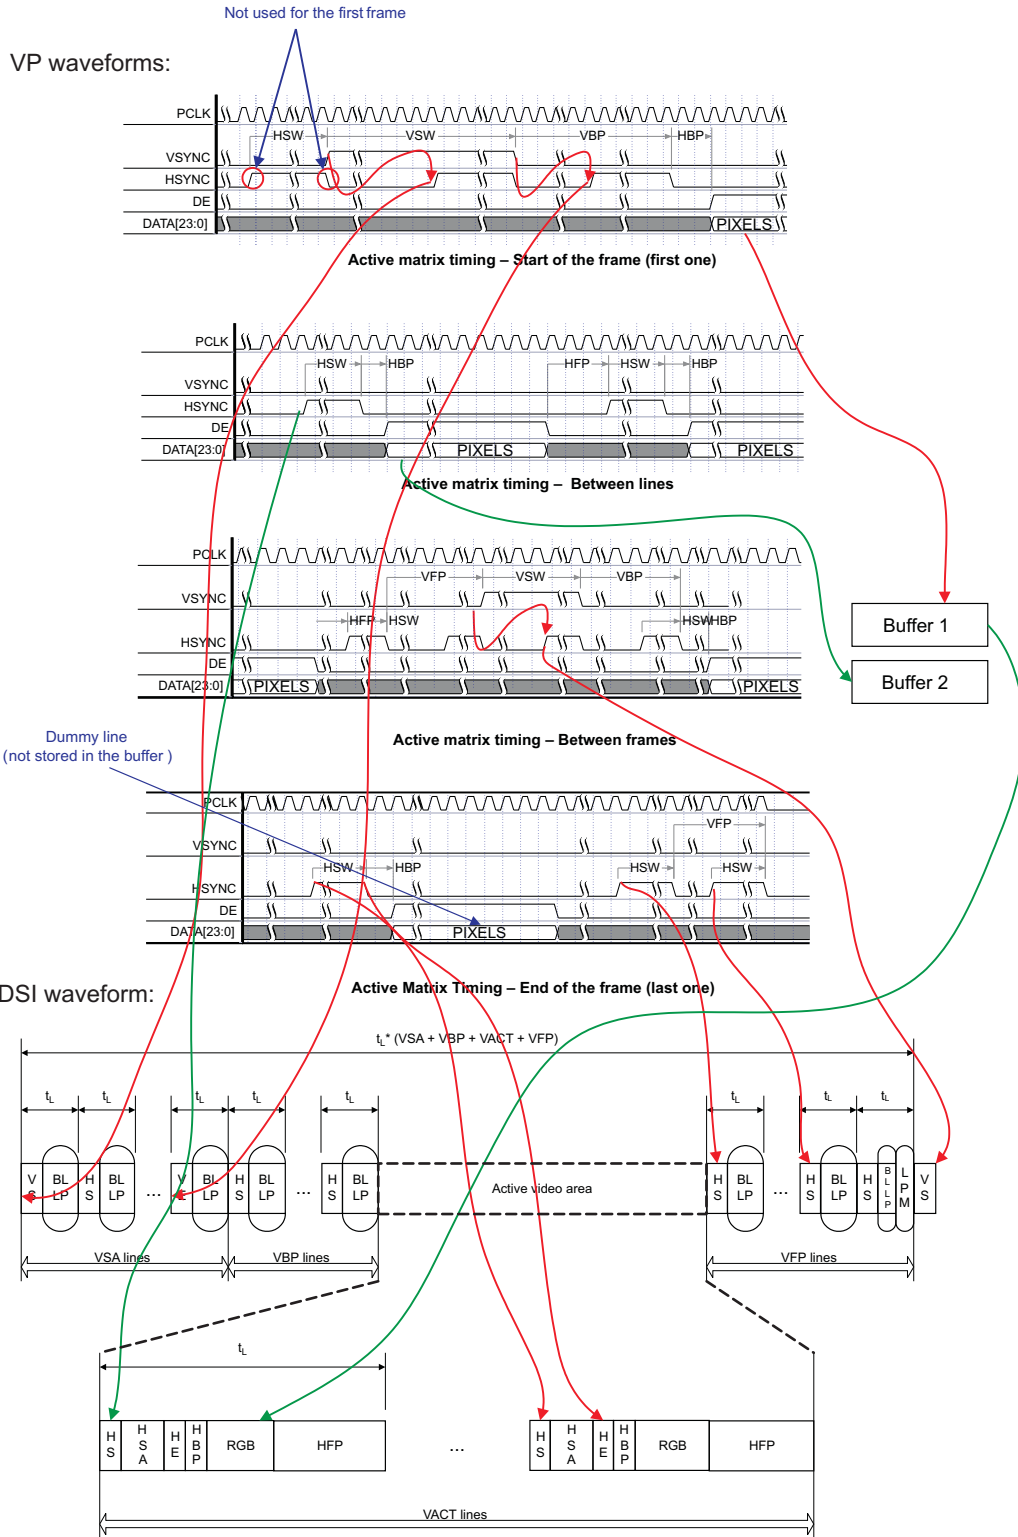

Figure 7-34, Figure 7-35, and Figure 7-36 show these three video modes.

Figure 7-35. DSI Video Mode Without Burst (One-Line Buffer)

dss-137

Figure 7-36. DSI Video Mode With Burst (Two-Line Buffers)

dss-138

NOTE: In [Figure 7-34](#), [Figure 7-35](#), and [Figure 7-36](#):

- When HSync start and Hsync end short packets are not generated (HSA does not exist), HBP signal must be different from 0.
- The software must ensure that VBP is always defined so that there is at least one HSYNC during VBP.
- In blanking low-power mode (BL-LP), two options are possible
 - The lane remains in ULPS, and the [DSI_CTRL\[20\]](#) BLANKING_MODE bit is set to 0x0.
 - Dummy bytes are sent during LP with the [DSI_CTRL\[20\]](#) BLANKING_MODE bit set to 0x1; the number of sent bytes is determined by the [DSI_VM_TIMING6\[15:0\]](#) BL_LP_INTERLEAVING bit field.

If the signal VP_DE is not asserted during enough VP_PCLK cycles to be able to capture the number of bytes defined in the word count of the header, the module must send the valid data received on the video port followed by bytes of 0s to match the required number of bytes to transmit. The VP_PCLK must be present during all extra cycles where the DSI protocol engine is expecting pixels.

If the VP_DE signal is asserted for too many VP_PCLK cycles, the module should stop capturing the data on the video port while the number of bytes to capture, as defined in the word count field of the header, is reached.

The HS must check that the received synchronization events on the video port (VSYNC and HSYNC) are within the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out-of-sync must be generated and the interface must be disabled (DSS.DSI_CTRL[0] IF_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field.

7.2.2.2.2 Video Port Used on Command Mode

If the video port is used for command mode, the VP_HSYNC, VP_VSYNC, and VP_DE signals are not used. [Table 7-12](#) describes the active signals on the video port.

Table 7-12. Video Interface in the Context of Command Mode

Signal Name	Type ⁽¹⁾	Description
VP_DATA[23:0]	I	Parallel output data: bits 0 to 23
VP_PCLK	I	One pulse is generated every time new data is output on the data bus
VP_STALL	O	The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated).
VP_CLK	I	Display controller internal clock: It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage and 96 MHz at low voltage.

⁽¹⁾ I = Input, O = Output

NOTE: The stall signal must be deasserted to receive pixels and asserted to stop receiving pixels.

[Figure 7-37](#) and [Figure 7-38](#) show the VP_STALL signal assertion and deassertion on rising and falling edges, respectively.

NOTE: In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Figure 7-37. Stall Timing With Pixel on Rising Edge

dss-187

Figure 7-38. Stall Timing With Pixel on Falling Edge

dss-188

To stop the transfer, the VP_STALL signal must be asserted when the last data is output. The data can be output on the rising or falling edge of the VP_PCLK through registers in the display controller module. The case with data output on falling edge of VP_PCLK is supported by the DSI protocol engine.

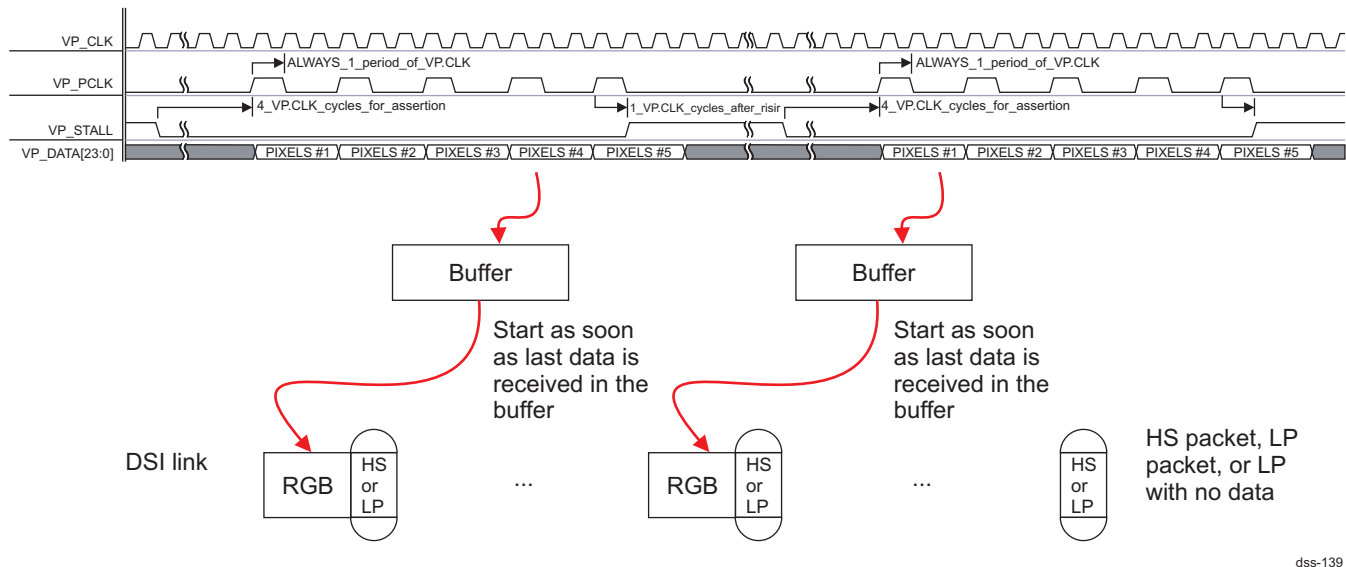

The VP_PCLK clock is generated from VP_CLK; these two clocks are balanced. Assertion and deassertion of VP_PCLK is done on the rising edge of VP_CLK. The width of the VP_PCLK pulse depends on the configuration of the clock divisor in the display controller (DSS.DISPC_DIVISOR[7:0] PCD bit field). In the DSI protocol engine, the information is defined in the DSS.DSI_CTRL[4] VP_CLK_RATIO bit and must be aligned with the display controller configuration.

Deassertion of the VP_STALL signal must occur at least 4 VP_CLK cycles before assertion of VP_PCLK. Assertion of VP_STALL must occur one cycle VP_CLK after deassertion of VP_PCLK for the last pixel to be transferred. The VP_CLK clock is generated by the display controller under software control. It can be kept running between assertion and deassertion of VP_STALL.

The word count (WC) defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register for the virtual channel (VC) associated with the video port, indicates the number of bytes to receive (one line or two lines can be used, depending on the WC and size of the line buffer). The total size defined in the WC of the header register cannot exceed the size of the line buffer multiplied by the number of buffer lines.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined in the DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.

Figure 7-39 shows the data flow in command mode using the video port.

Figure 7-39. Data Flow in Command Mode Using the Video Port

dss-139

Two command modes are available:

- One line buffer: The data are stored in the line buffer before being sent.
- Two line buffers: The two lines are used if the word count defined in the [DSS.DSI_VCn_LONG_PACKET_HEADER](#) register is bigger than the line size; otherwise, one line buffer is used.

NOTE: In command mode, the video port can only be used in one or two line buffer configuration. The no-line buffer configuration is not allowed.

The packets can be sent using high-speed or low-speed.

NOTE: The DCS command in the payload can be inserted automatically using the [DSI_CTRL\[24\]](#) [DCS_CMD_ENABLE](#) bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and the DCS Write Continue command for all subsequent packets.

7.2.2.2.3 Burst Mode

When the burst mode is enabled, the video port receives data from the display controller at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double-line buffer of 1024 x 24-bit pixels maximum). The read speed of the line can be twice the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. The burst mode uses a dual-line buffer.

The DSI port can output data from one line buffer while the second one is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the whole video port line is transferred into a line buffer. The switch is controlled by the VP_HS signal on the video port side and by internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

NOTE: The line buffers are used to store the pixels only. The synchronization codes are not stored in the line buffers. They must be sent according to the video port timings.

7.2.2.3 Multilane Layer

Peripherals do not typically have high bandwidth requirements for returning data to the host processor. To keep designs simple and improve interoperability, all DSI-compliant systems must use only Lane 1 in LP mode for returning data from a peripheral to the host processor.

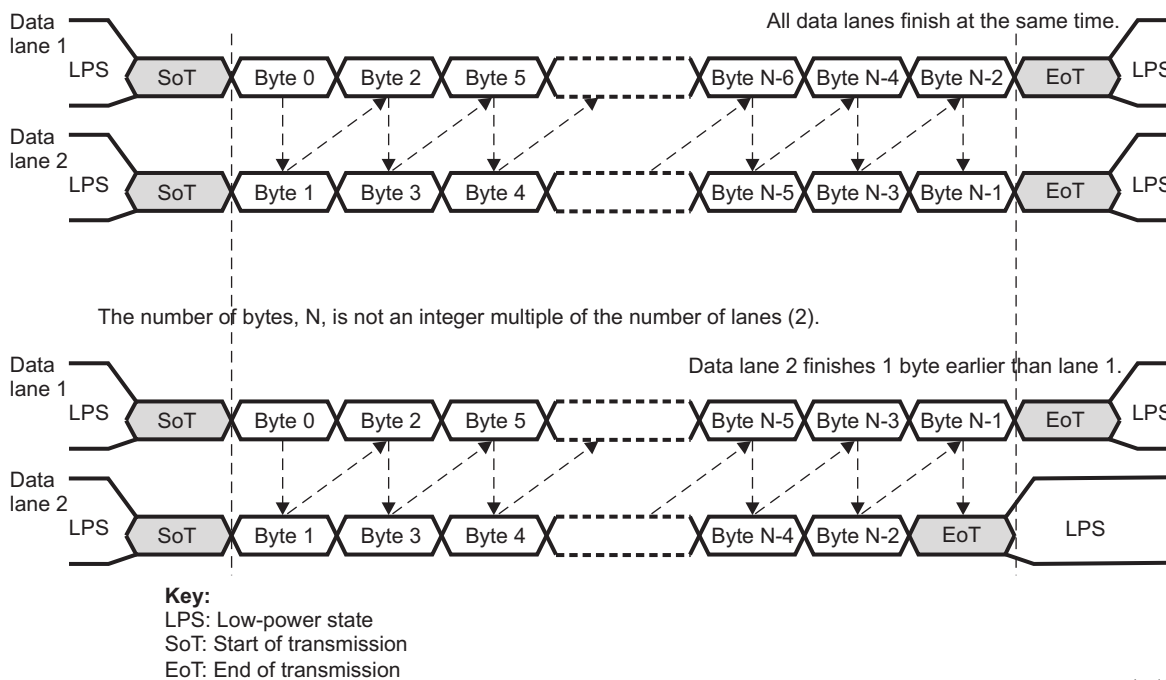

7.2.2.3.1 SoT and EoT in Multilane Configurations

Since a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its valid data signal into all lanes for which there is no further data. Although all lanes start simultaneously with parallel SoTs, each lane operates independently and may complete the HS transmission before the other lanes, sending an EoT one cycle (byte) earlier.

7.2.2.3.2 Lane Splitter

The lane splitter can split the byte stream into 2 lanes (for 1 lane, the splitter is bypassed). Figure 7-40 and Figure 7-41 show the byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is only used when packets are sent using high-speed mode (HS). In low-power mode (LP), only one data lane is used (Lane 1).

Figure 7-40. Two Data Lane Configuration

dss-140

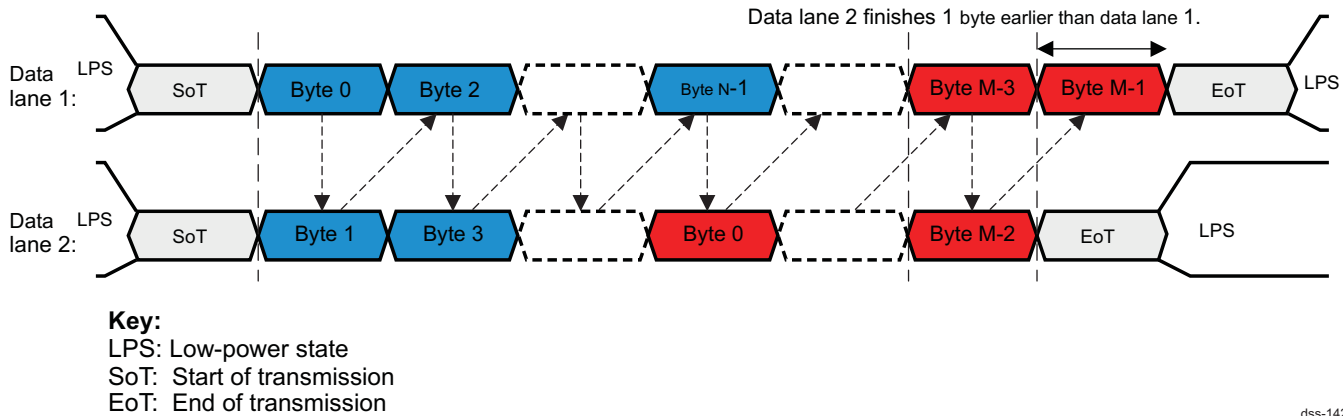

Figure 7-41. One Data Lane Configuration

dss-329

In case of back-to-back packets, the byte stream is considered as a single packet by the splitter module. [Figure 7-42](#) shows the example of two packets sent back to back. N bytes for the first packet and M bytes for the second one.

Figure 7-42. Two Packets Using Two-Data Lane Configuration (Example)

dss-142

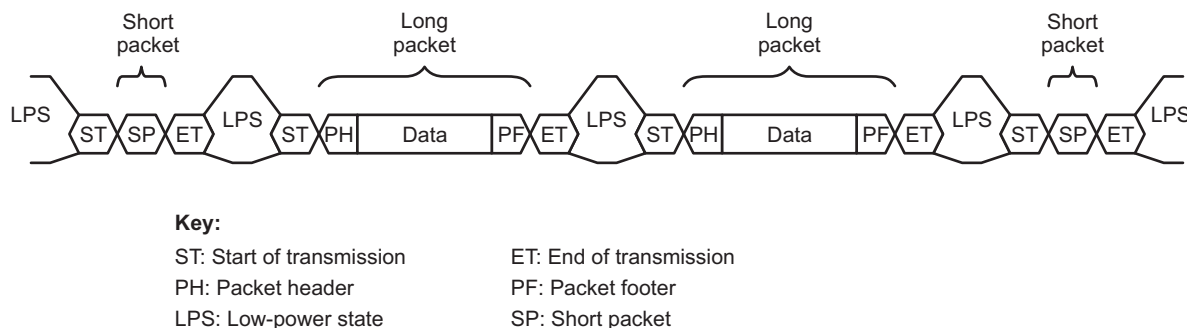

7.2.2.4 Protocol Layer

The low level protocol (LLP) is a byte-oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the physical layer. Packets can be sent using high-speed or low-speed mode. LLP is selected through DSI registers. The features of the DSI protocol layer are:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

[Figure 7-43](#) shows the protocol layer with short and long packets.

Figure 7-43. Protocol Layer With Short and Long Packets

dss-143

7.2.2.4.1 Short Packet

[Figure 7-44](#) shows the structure of the short packet. A short packet must contain an 8-bit data ID followed by two command or data bytes and an 8-bit ECC; a packet footer must not be present. Short packets must be 4 bytes in length. The ECC byte allows correction of single-bit errors and detection of 2-bit errors in the short packet.

Figure 7-44. Short Packet Structure

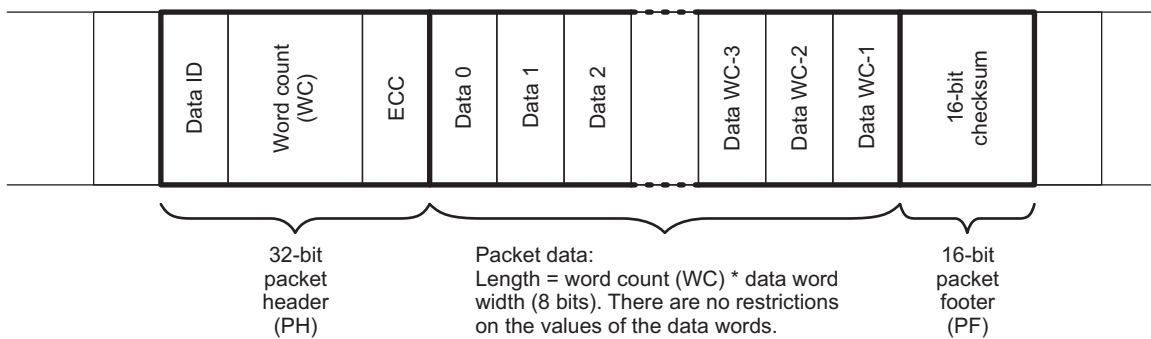

NOTE: The short packets can be sent in low-power mode or in high-speed mode.

7.2.2.4.2 Long Packet

Figure 7-45 shows the structure of the low-level protocol long packet. A long packet must consist of three elements: A 32-bit packet header (PH), an application-specific data payload with a variable number of bytes, and a 16-bit packet footer (PF). The packet header is further composed of three elements: An 8-bit data identifier, a 16-bit word count, and 8-bit ECC. The packet footer has one element, a 16-bit checksum. Long packets can be from 6 to 65,541 bytes in length.

Figure 7-45. Long Packet Structure

- The data identifier defines the VC for the data and the DT for the application-specific payload data.
- The word count defines the number of bytes in the data payload between the end of the packet header and the start of the packet footer. Neither the packet header nor the packet footer must be included in the word count.
- The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header. This includes the data identifier and the word count fields.

After the end of the packet header, the receiver reads the next word count * bytes of the data payload. There are no limitations on the value of a data word within the data payload block, that is, no embedded codes are used. Once the receiver has read the data payload, it reads the checksum in the packet footer. The host processor must always calculate and transmit a checksum in the packet footer. Peripherals are not required to calculate a checksum. Also note the special case of zero-byte data payload: If the payload has length 0, then the checksum calculation results in (0xFFFF). If the checksum is not calculated, the packet footer must consist of 2 bytes of all zeros (0x0000). In the generic case, the length of the data payload must be a multiple of bytes. In addition, each data format may impose additional restrictions on the length of the payload data, that is, multiple of 4 bytes. Each byte is transmitted LSB first. Payload data may be transmitted in any byte order, restricted only by data format requirements. Multibyte elements such as word count and checksum must be transmitted least-significant byte first.

NOTE: The long packets can be sent in low-power mode or high-speed mode.

7.2.2.4.3 Data Identifier

The data identifier byte contains the virtual VC ID value and the DT value, as shown in Figure 7-46. The VC ID is contained in the 2 MSBs of the data identifier byte. The DT value is contained in the 6 LSBs of the data identifier byte. DI[7:6]: These 2 bits identify the data as directed to one of four VCs. DI[5:0]: These six bits specify the DT.

Figure 7-46. Data Identifier Structure

dss-146

7.2.2.4.4 Virtual Channel ID - VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data using the VC ID field of the header for packets targeted at different peripherals. The VC ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Note that each packet sent in a single transmission have its own VC assignment and can be directed to different peripherals. The VC ID is defined in the [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) and [DSS.DSI_VCn_LONG_PACKET_HEADER](#) registers for short and long packets, respectively. It should not be modified by hardware. There is one set of registers for each VC. Each set of registers defines the characteristics of the traffic between the host and the display associated with the VC.

Figure 7-47 shows the VC controller.

Figure 7-47. Virtual Channel Controller

dss-147

7.2.2.4.5 Data Type Field DT[5:0]

The DT field specifies whether the packet is a long or short packet type and the packet format. The DT field, along with the word count field for long packets, informs the receiver on how many bytes to expect in the remainder of the packet. This is necessary because there are no special packet start/end sync codes to indicate the beginning and end of a packet. This permits packets to convey arbitrary data, but it also requires the packet header to explicitly specify the size of the packet.

7.2.2.4.6 Pixel Data Formats in Video Mode

The host can send different pixel formats in video mode. [Table 7-13](#) summarizes the pixel formats supported by the DSI interface in video mode.

Table 7-13. Pixel Data Format in Video Mode

Mode	Description
RGB888 (using 24-bit container)	RGB888
RGB666 (using 24-bit container)	RGB666
RGB666 (18-bit packet using 18-bit container)	RGB666_PACKET
RGB565 (using 16-bit container)	RGB565

7.2.2.4.7 Synchronization Codes

Each frame can be identified by two synchronization codes: One for the start of vertical synchronization pulse (VSSC) and one for the end of the vertical synchronization pulse (VSEC). Each line can be identified by two synchronization codes: One for the start of horizontal synchronization pulse (HSSC) and one for the end of the horizontal synchronization pulse (HSEC). The synchronization events may not be required by the display (peripheral): They are optional. Users can program which sync events are generated to the display from the timings received from the display controller in video mode. When data are received on the L4 interconnect slave port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L4 interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the display controller to receive the synchronization events to automatically generate the short synchronization packets to the peripheral. When the DSI protocol engine detects that the VSYNC signal from the display controller transitions from inactive to active state, the VSSC short packet replaces the following HSSC corresponding to the following HSYNC synchronization short packet (if the generation is enabled). When the transition from active to inactive state is detected, the VSEC short packet is generated (if the generation is enabled) replacing the HSSC synchronization packet corresponding to the following HSYNC. When the DSI protocol engine detects that the HSYNC signal from the display controller transition from inactive to active state, the HSSC short packet is generated (if the generation is enabled). When the transition from active to inactive state is detected, the HSEC short packet is generated (if the generation is enabled). For the first frame, any HSYNC and data received on the video port before the first VSYNC should be ignored. Because the first VSYNC sent to the display is also recognized as a HSYNC for the first line, there should be no HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses the short packets. [Table 7-14](#) summarizes the 6-bit DT synchronization code values.

Table 7-14. Synchronization Codes

Synchronization Code	Value	Comments
V sync start code (VSSC)	0x1	Optional
V sync end code (VSEC)	0x11	Optional
H sync start code (HSSC)	0x21	Optional
H sync end code (HSEC)	0x31	Optional

7.2.2.4.8 Blanking

To keep the DSI link in HS state while using the video mode, during blanking periods, the long blanking packets are sent to the display. The DSS.DSI_VM_TIMING_i (I between 1 and 7) registers define the size of the long blanking packets after:

- Horizontal sync start code (short packet)
- Horizontal sync end code (short packet)
- Vertical sync start code (short packet)
- Vertical sync end code (short packet)
- Pixels (long packet)

[Table 7-15](#) defines the short packet values for the synchronization packets:

Table 7-15. Sync Short Packet Values

Virtual Channel ID	Sync Code	Header (1st Byte)	Header (2nd Byte): Data Field LSB	Header (3rd Byte): Data Field MSB	Header (ECC)
0x0	0x1	0x1	0x0	0x0	See note following this table
	0x11	0x11			
	0x21	0x21			
	0x31	0x31			
0x1	0x1	0x41			
	0x11	0x51			
	0x21	0x61			
0x2	0x31	0x91			
	0x1	0x81			
	0x11	0x81			
	0x21	0xA1			
0x3	0x31	0xB1			
	0x1	0xC1			
	0x11	0xD1			
	0x21	0xC1			
	0x31	0xF1			

NOTE:

- If the ECC is enabled by setting the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit to 1 for the VC in video mode, the ECC value is calculated; otherwise, 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit to 1 for the VC in video mode, the check-sum value is calculated; otherwise, 0x00 is used for the blanking long packets.
- In other cases, when the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets, except when the header is provided by the register, since the ECC field is available in the register. It can be used to generate invalid ECC values when the header is provided by the register.

The link [lane(s) and clock separately] can be put in ULPS mode. While using the blanking values formerly defined, the packets (short and long) are considered in HS mode.

Timing parameters VSA, VBP, VFP, HSA, HBP, HFP, VACT, and t_L are defined in the DSS.DSI_VM_TIMINGx (x between 1 and 7) register. HSA, HBP, HFP, and t_L are defined using the byte clock unit (TxByteClkHS) and also in low-power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined in term of number of lines. When the HS blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (taking into account the 4-byte header and the 2-byte check sum).

The configuration of the display controller timing generator must be used when the display controller timings are used to generate the DSI HS video mode transfer.

Special care must be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period cannot be used for sending any data from the TX FIFO. When the blanking period starts with one HS packet from one VC, it can only be followed by another HS packet from the same VC, or by trigger (BTA for example). When there is no more HS data to send for this VC, the lane is in LPS. When the blanking period starts with one LP packet from one VC, it can only be followed by another LP packet from the same VC, by another VC, by trigger (BTA

for example), or by extra LP NULL packets. If the trigger has been sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put into LPS. If the lanes must be kept in HS mode during blanking periods (except for the last blanking period of the frame), the HS blanking packets must be used. In case one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in ULPS.

Figure 7-48 and Figure 7-49 show a nonburst transfer in DSI video mode with, and without VE and HE, respectively.

Figure 7-48. DSI Video Mode: Nonburst Transfer With VE and HE

dss-148

Figure 7-49. DSI Video Mode: Nonburst Transfer Without VE and HE

dss-149

NOTE: HSA timing is not used and does not have to be programmed when HE short packet is not generated.

Figure 7-50. DSI Video Mode: Burst Transfer Without VE and HE

dss-150

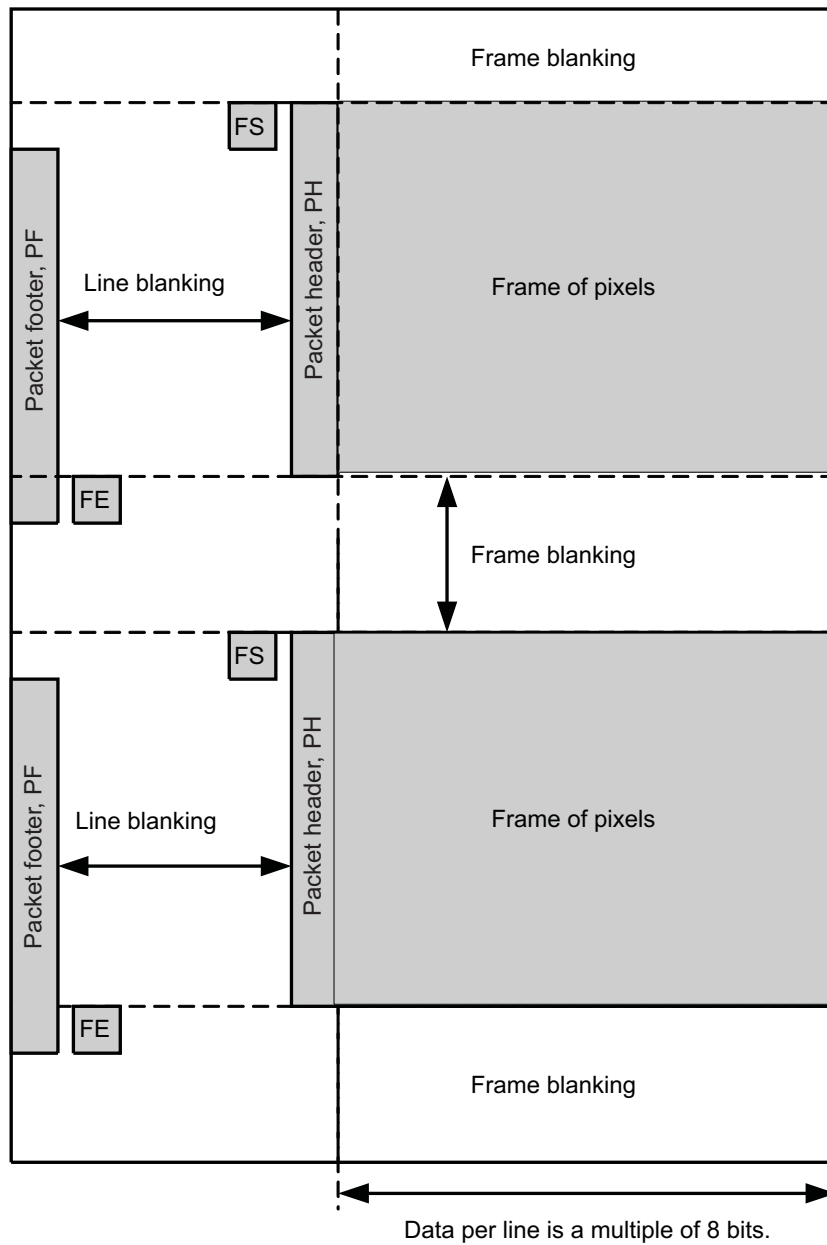

NOTE: HSA timing is not used and does not have to be programmed when HE short packet is not generated.

In Figure 7-49 and Figure 7-50, if HSync end short packet is not generated (HSA does not exist), HBP must be other than 0.

7.2.2.4.9 Frame Structures

7.2.2.4.10 Virtual Channels

The DSI protocol layer transports VCs. The purpose of VCs is to separate different data flows, which are interleaved in a same data stream. Each VC is identified by a unique channel identification number in the packet header. The channel identification number is encoded in 2-bits. The DSI protocol engine determines the channel identifier number to be used for generating the packet header and multiplexes the interleaved data streams. The DSI protocol engine supports multiple concurrent VCs: Up to 4. [Table 7-16](#) summarizes the VC values used for each channel.

Table 7-16. Virtual Channel Values

Virtual Channel Number	Value
Virtual channel 0	0x0
Virtual channel 1	0x1
Virtual channel 2	0x2
Virtual channel 3	0x3

In the case of multiple displays connected to the single DSI port on the host, a hub may be used to route the data stream to the appropriate display based on the VC ID. Typically, VC ID 0x0 is used for the primary display and 0x1 for the secondary. The hub may have its own VC ID to provide communication capability between the host and the hub.

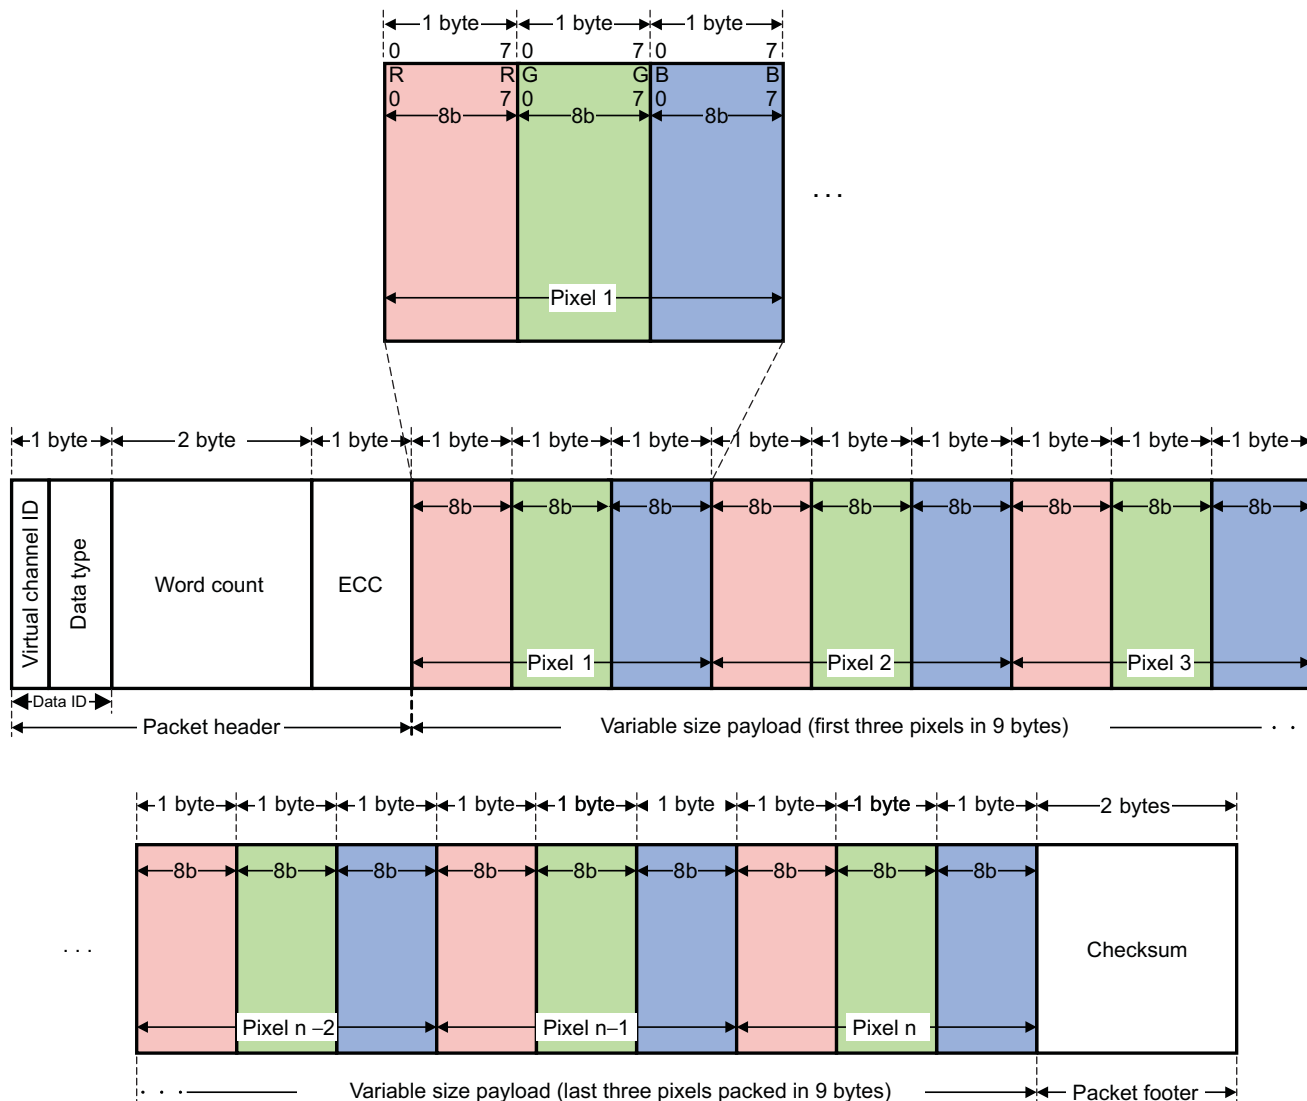

7.2.2.5 Pixel Data Formats

This section summarizes how the DSI supported pixel data formats in video mode are transmitted over the serial interface. For pixel formats in command mode. The DSI protocol engine can cope with all data formats given that the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

7.2.2.5.1 24 Bits per Pixel - RGB Color Format, Long Packet

[Figure 7-54](#) shows the RGB888 format.

Figure 7-54. 24 Bits per Pixel RGB Color Format, Long Packet

dss-154

Packed pixel stream 24-bit format is a long packet used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (8 bits), green (8 bits), and blue (8 bits), in that order. Each color component occupies one byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first, the MSB last.

7.2.2.5.2 18 Bits per Pixel (Loosely Packed) - RGB Color Format, Long Packet

Figure 7-55 details the RGB666 format.

Figure 7-55. 18 Bits per Pixel (Loosely Packed) RGB Color Format, Long Packet

dss-155

In the 18-bit pixel loosely-packed format, each R, G, or B color component is six bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires three bytes as it is transmitted across the link. This requires more bandwidth than the packed format, but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (6 bits), green (6 bits), and blue (6 bits) in that order. Within a color component, the LSB is sent first, the MSB last.

7.2.2.5.3 18 Bits per Pixel (Packed) - RGB Color Format, Long Packet

Figure 7-56 details the RGB666_PACKED format.

Figure 7-56. 18 Bits per Pixel (Packed) RGB Color Format, Long Packet

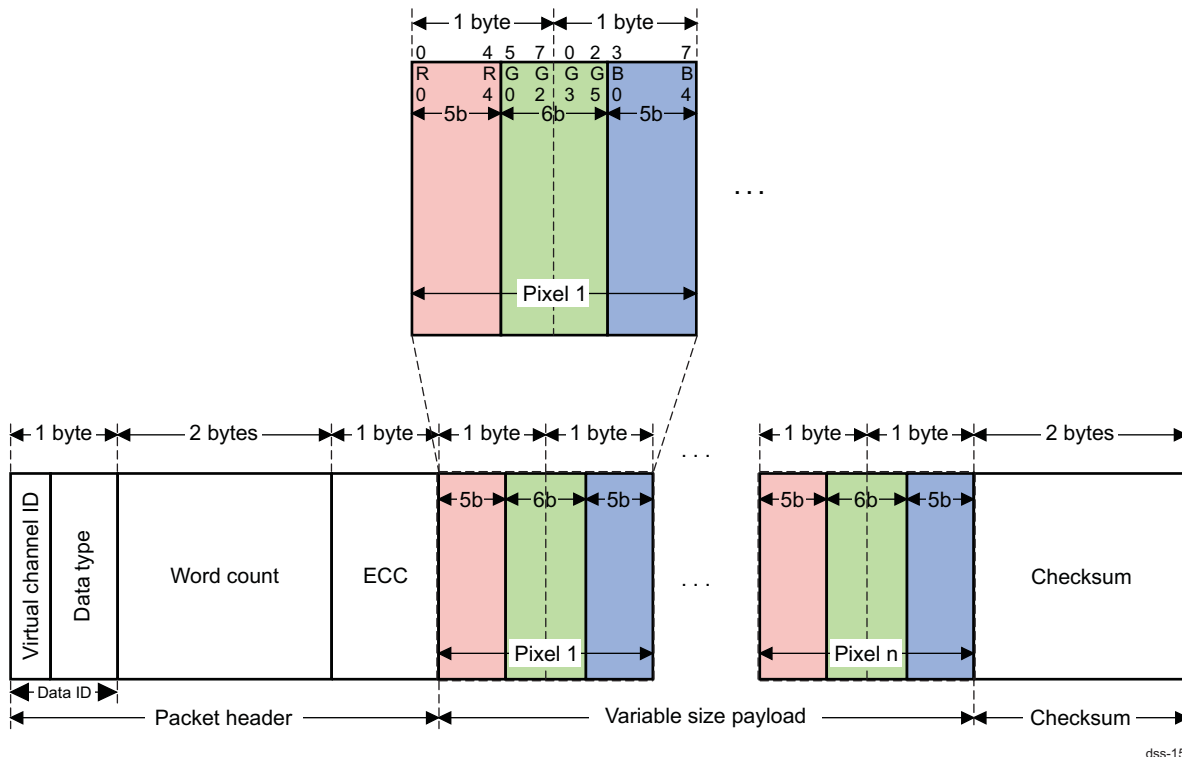

dss-156

Packed pixel stream 18-bit format (packed) is a long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is red (6 bits), green (6 bits), and blue (6 bits), in that order. Within a color component, the LSB is sent first, the MSB last. With this format, it is strongly recommended that the total line width be a multiple of four pixels (nine bytes).

7.2.2.5.4 16 Bits per Pixel - RGB Color Format, Long Packet

Figure 7-57 details the RGB565 format.

Figure 7-57. 16 Bits per Pixel RGB Color Format, Long Packet

Packed pixel stream 16-bit format is a long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is five bits red, six bits green, five bits blue, in that order. Note that the *green* component is split across two bytes. Within a color component, the LSB is sent first, the MSB last.

7.2.3 TV Display Support

The TV display path includes the following modules:

- Display controller
- Video encoder
- Video DAC stage comprising two single 10-bit DACs (AVDAC1 and AVDAC2) with video amplifiers

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder.

The video encoder converts RGB video signals to conform to the NTSC/PAL standard analog video. The video encoder includes an integrated synchronization signal generator and two single channel video digital-to-analog converters (DACs) with video amplifiers, data manager, luma stage, chroma stage, modulator, and a control interface.

The video encoder also provides the synchronization signals to the display controller: VSYNC, active Video (AVID), and field ID (FID).

Figure 7-58 is a block diagram of the TV display interface (S-video mode, DC coupled, High Full Scale Swing).

Figure 7-58. TV Display Interface (S-video mode, DC coupled, High FS Swing)

Figure 7-59 is a block diagram of the TV display interface (Composite mode, DC coupled, High Full Scale Swing).

Figure 7-59. TV Display Interface (Composite Mode, DC coupled, High FS Swing)

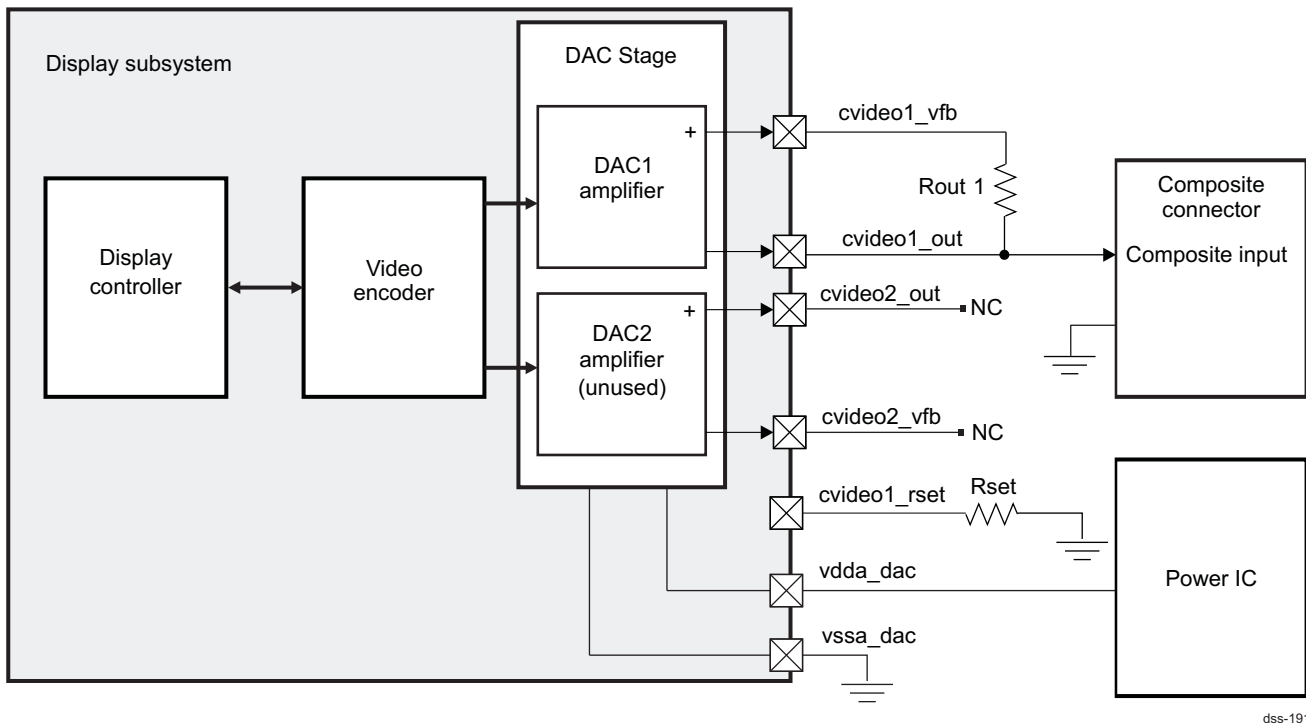

Figure 7-60 is a block diagram of the TV display interface (Composite mode, AC coupled, Low Full Scale Swing).

Figure 7-60. TV Display Interface (Composite Mode, AC coupled, Low FS Swing)

dss-401

NOTE: In composite video mode, the video DAC2 chroma output must be disabled by setting the `DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE` bit to 0.

Figure 7-61 is a block diagram of the TV display interface (Bypass mode, Dual Channel).

Figure 7-61. TV Display Interface (Bypass Mode, Dual Channel)

* (Rout1 and Rout2 loads can be integrated in the amplifier, and thus not needed as external components)

dss-402

Table 7-17 describes the interface signals to/from the TV set for TV display support.

Table 7-17. TV Display Interface Pins

Pin Name	Type ⁽¹⁾	Description
cvideo1_out	O	Analog luma or composite video output. An external resistor Rout1 is connected between this node and the cvideo1_vfb pin. Note that this is the output node that drives the load (75 Ω).
cvideo2_out	O	Analog chroma video output. An external resistor Rout2 is connected between this node and the cvideo2_vfb pin. This is the output node that drives the load (75 Ω).
cvideo1_vfb	O	Amplifier feedback node. An external resistor Rout1 is connected between this node and cvideo1_out.
cvideo2_vfb	O	Amplifier feedback node. An external resistor Rout2 is connected between this node and cvideo2_out.
cvideo1_rset	I/O	External resistor pin to set the reference current of the AVDAC1. The value of the resistor (Rset) depends on the mode of operation. Refer to Table 7-18 , <i>Typical values for Rout, Rset and Cout</i> .
vdda_dac	Power	Analog supply voltage for the video DAC stage
vssa_dac	Power	Analog ground for the video DAC stage

⁽¹⁾ O = Output, Power = Power pin

[Table 7-18](#) lists the typical values for the Rout1/2 and Rset resistors and the Cout capacitor, for different modes of the TV display interface.

Table 7-18. Typical values for Rout, Rset and Cout

	S-video, DC coupled, High FS Swing	Composite, DC coupled, High FS Swing	Composite, AC coupled, Low FS Swing	Bypass, Dual channel	Unit
Rout 1	2700	2700	2700	1500	Ohm
Rout 2	2700	N/A	N/A	1500	Ohm
Rset	4700	4700	6800	10000	Ohm
Cout	N/A	N/A	220	N/A	μF

CAUTION

- High full-scale swing is the default mode. Low-swing mode does not comply with the NTSC and PAL video standards. It must be used only for backward compatibility to the OMAP35x.
- All resistor values in [Table 7-18](#) must be within $\pm 1\%$ tolerance range.
- cvideo1_out and cvideo2_out are very high-frequency analog signals and must be routed with extreme care. As a result, the path of these signals must be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the two channels. cvideo1_vfb and cvideo2_vfb pins are the most sensitive pins in the TV out system. The onboard parasitic capacitance associated with these two pins must be less than 0.5 pF. Low onboard resistance is required for the traces that connect the Rout1/Rout2 to the cvideo1_vfb/cvideo2_vfb and TV OUT pins (cvideo1_out and cvideo2_out). The resistance on those trace affects output impedance matching. Therefore, Rout1 and Rout2 resistors are suggested to be placed as close as possible to the device pins. The onboard traces lead to the TV OUT pins must have a characteristic impedance of 75 Ω starting from the closest possible place to the device pin output.
- If the TV output is not used, the following configurations for the AVDACs pins must be applied:
 - Configuration 1
 - cvideo1_out must be grounded.
 - cvideo1_vfb must be grounded.
 - cvideo2_out must be grounded.
 - cvideo2_vfb must be grounded.
 - cvideo1_rset must be grounded.
 - vdda_dac must be grounded.
 - vssa_dac must be grounded.
 - Configuration 2
 - cvideo1_out must be floating, left unconnected.
 - cvideo1_vfb must be floating, left unconnected.
 - cvideo2_out must be floating, left unconnected.
 - cvideo2_vfb must be floating, left unconnected.
 - cvideo1_rset must be floating, left unconnected.
 - vdda_dac must be grounded.
 - vssa_dac must be grounded.
- To avoid current leakage, the following bits must be set to 0:
 - DSS.DSS_CONTROL[5] DAC_POWERDN_BGZ
 - DSS.VENC_OUTPUT_CONTROL[2:0]
 - PRCM.CM_FCLKEN_DSS[2] EN_TV
 - CONTROL.CONTROL_DEVCONF[18] TVOUTBYPASS

7.2.3.1 TV Output and Data Format

The output data to the TV set are the analog composite data from the video DAC stage. The following video standards are supported:

- NTSC-J, M

- PAL-B, D, G, H, I
- PAL-M

7.2.3.2 Digital-to-Analog Converters

The video DAC stage includes the following main features:

- 1.1-V digital power supply, 1.8-V analog power supply
- 10-bit resolution
- DNL within 1 LSB and INL within 1 LSB (in bypass mode)
- Sample rate of up to 60 mega samples per second (MSPS)
- Support composite/S-video DC or AC coupled output
- Support TVOUT buffer bypass mode (DAC-only mode)
- Full-scale voltage output: minimum 1.2 V_{pp} with a 75-Ω load
- Internal TV detect feature
- Signal-to-noise ratio (SNR) is 54 dB (taking into account the ac coupling)
- Suitable for low-power consumer video applications
- Power-down mode with less than 12-μA standby current
- Differential gain error and differential phase error: within 3 percent and 1 degree, respectively

NOTE: To enhance the TV color display, it is highly recommended to set the DSS.DSS_CONTROL[4] DAC_DEMEN bit.

For more information about the video DAC stage architecture and configuration, see [Section 7.4.7.7, Video DAC Stage – Architecture and Control](#).

7.3 Display Subsystem Integration

This section describes the integration of the display subsystem and details clocks, resets, hardware requests, and power modes.

[Figure 7-62](#) shows the integration of the display subsystem in the device.

Figure 7-62. Display Subsystem Integration

7.3.1 Clocking, Reset, and Power-Management Scheme

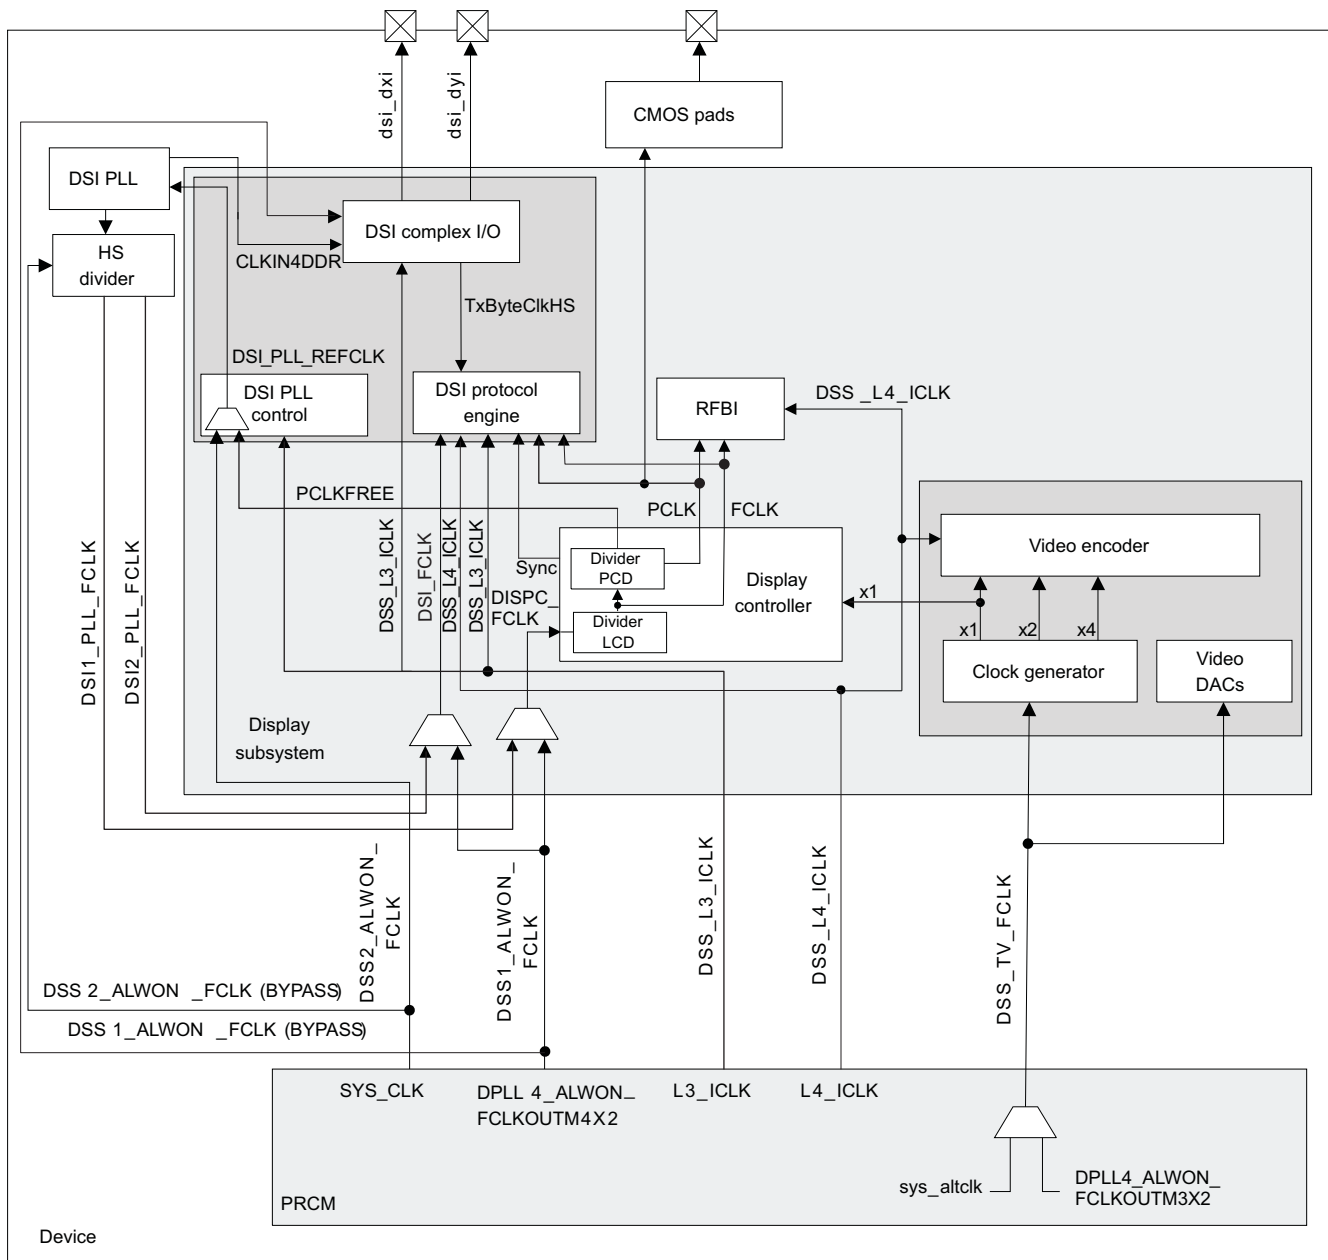

7.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides six clock signals to the display subsystem: The L3 interface clock (DSS_L3_ICLK) and the L4 interface clock (DSS_L4_ICLK), with frequencies equal to the L3 interconnect clock and the L4 interconnect clock, respectively; two configurable functional clocks (DSS1_ALWON_FCLK and DSS2_ALWON_FCLK); and one other functional clock (DSS_TV_FCLK).

The DSI PLL provides two functional clock signals to the display subsystem: DSI1_PLL_FCLK and DSI2_PLL_FCLK.

Figure 7-63 details the clock tree for the display subsystem.

Figure 7-63. Display Subsystem Clock Tree

camdss-158

NOTE: A synchronization signal is sent by the display controller (DISPC) to the DSI protocol engine. This signal, named DISPC_UPDATE_SYNC, is used to inform the DSI protocol engine that it must be unsynchronized with the display controller.

Table 7-19 describes the different clocks with their possible frequency values.

Table 7-19. Display Subsystem Clocks

Clock Signal	Attribute	Module	Frequency	Comment
DSS_L3_ICLK	L3 interface clock	DSS	(See Chapter 3, Power, Reset, and Clock Management)	L3 interface clock from PRCM
DSS_L4_ICLK	L4 interface clock	DSS	(See Chapter 3, Power, Reset, and Clock Management)	L4 interface clock from PRCM
DSS1_ALWON_FCLK	Functional clock	DISPC, DSI protocol engine	Up to 173 MHz at nominal voltage (OPP100), and up to 100 MHz at low voltage (OPP50)	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK)
DSS2_ALWON_FCLK	Functional clock	DSI PLL	12/13/16.8/19.2/26/38.4 MHz	From PRCM: SYS_CLK
DSI1_PLL_FCLK	Functional clock	DISPC	Up to 173 MHz at nominal voltage (OPP100), and up to 100 MHz at low voltage (OPP50)	From DSI PLL and HS divider
DSI2_PLL_FCLK	Functional clock	DSI protocol engine	Up to 173 MHz at nominal voltage (OPP100), and up to 100 MHz at low voltage (OPP50)	From DSI PLL and HS divider
DSS_TV_FCLK	Functional clock	DSS, video mode DAC	54 MHz or sys_alt_clk (up to 59 MHz)	From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK) or External input clock (See Chapter 3, Power, Reset, and Clock Management)

To enable or disable each functional clock, set the following bit (1: Enable, 0: Disable):

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit to enable DSS1_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit to enable DSS2_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[2] EN_TV bit to enable DSS_TV_FCLK

To enable or disable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks, write (1: Enable, 0: Disable) to the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit.

NOTE: Note that it is not possible to gate/stop L3 clock and keep L4 clock running.

- L3 and L4 interface clock

The DSS_L3_ICLK clock is only used by the display controller interface to fetch the pixel data. The DSS_L4_ICLK is used to access the L4 interconnect for configuring all the display subsystem registers.

NOTE: A clock generated internally from the L3 interface clock allows the submodules to be configured and is the functional clock for the RFBI. All the display subsystem registers are configured through the display subsystem register.

- Display controller functional clocks

The display controller can use either the DSS1_ALWON_FCLK or the DSI1_PLL_FCLK functional

clock.

To select the DSS1_ALWON_FCLK functional clock (the default clock selected after reset), write 0 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit; to select the DSI1_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit.

NOTE: The DSS1_ALWON_FCLK and DSI1_PLL_FCLK functional clocks must be active (the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 and DSI PLL programmed correctly) to switch from one functional clock to another. The new functional clock is effective when the next vertical blanking interval occurs. This is true only if the DSS.DISPC_CONTROL[5] GOLCD bit is set to 1.

Depending on the DPLL4 input clock frequency, the DSS1_ALWON_FCLK can be adjusted by setting the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.

- DSI PLL functional clock (DSI_PLL_REFCLK)

The DSI PLL controller module can use either the DSS2_ALWON_FCLK (from PRCM) or the PCLKFREE (from DISPC) functional clock. To select the DSS2_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit; to select the PCLKFREE functional clock, write 1 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit.
- DSI protocol engine functional clocks (DSI_FCLK)

The DSI protocol engine can use either the DSS1_ALWON_FCLK (from PRCM) or the DSI2_PLL_FCLK (from DSI PLL) functional clock. To select the DSS1_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit; to select the DSI2_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit.

NOTE: It is possible to switch between these two clocks, even when both of them are not active.

- There are five clock domains in the DSI module:
 - Byte clock domain:

TxByteClkHS is generated from the bit clock and converted into a byte clock. The maximum frequency is 112.5 MHz at nominal voltage (OPP100), and 100 MHz at low voltage (OPP50). It is generated by the DSI complex I/O.
 - Functional clock domain

The DSI_FCLK is the functional clock for the DSI protocol engine module. The maximum frequency is 173 MHz (nominal voltage) and 100 MHz (low voltage). It must always be equal to or higher than the byte (TxByteClkHS), L4 interconnect (DSS_L4_ICLK), and video port (VP_CLK) clocks. The software must configure the clocks correctly.
 - L4 interface clock domain

The DSS_L4_ICLK is used in the L4 interconnect port domain. The maximum frequency is 100 MHz at nominal voltage.
 - The video port domain

The pixel clock (PCLK) on the video port is used by the video port domain to capture the pixels from the display controller. The maximum frequency of VP_CLK used as the functional clock for the video port domain is 173 MHz at nominal voltage and 96 MHz at low voltage.
 - Serial Configuration Port (SCP) and Power Control (PWR) interfaces

The DSS_L4_ICLK is the functional clock.

NOTE:

- There is no clock domain for RxClkEsc because it is used as an enable and not as a clock by the DSI protocol engine module
- The clock domains are asynchronous (except for L4 interconnect port and SCP/PWR because both of them use DSS_L4_ICLK). The clocks used for the L4 interconnect port and SCP/PWR interface must be balanced.
- If video mode is used, the display controller functional clock must be generated using a clock from the DSI PLL.

- Video encoder functional clock

The DSS_TV_FCLK is divided into three balanced clocks, depending on the clock mode selected (see [Table 7-20](#)).

Table 7-20. Possible Digital Clock Division for the Video Encoder

Clock Output	Clock Mode	
	Clock Mode 0	Clock Mode 1
Video encoder clock 4x	DSS_TV_FCLK	DSS_TV_FCLK or 0 (gated)
Video encoder clock 2x	DSS_TV_FCLK/2	DSS_TV_FCLK
Video encoder clock 1x	DSS_TV_FCLK/4	DSS_TV_FCLK/2

The clock mode is defined by the [DSS_CONTROL\[2\]](#) VENC_CLOCK_MODE register bit:

- In the case of clock mode 1, the [DSS_CONTROL\[3\]](#) VENC_CLOCK_4X_ENABLE bit is used to control clock gating.
- In the case of clock mode 0, the VENC_CLOCK_4X_ENABLE bit must be set to 0x1 by software.

NOTE: After reset, clock mode 0 is selected by default, and the DSS_TV_CLK clock is disabled. The DSS_TV_CLK / 4 in mode 0, or the DSS_TV_CLK / 2 in mode 1, is used in the DISPC module to send data to the video encoder.

NOTE: Clock mode 1 can be used for power-saving purposes, or if a 27-MHz external clock is provided to the video encoder.

DSS_TV_FCLK can be adjusted depending on the DPLL4 input clock frequency by setting the PRCM.CM_CLKSEL_DSS[12:8] CLKSEL_TV bit field. If the DPLL4 is selected, the DSS_TV_FCLK is provided by the DPLL4_ALWON_FCLKOUTM3X2 clock.

NOTE: If the DSS_TV_FCLK is not provided by DPLL4 but rather by the sys_alt_clk pin, an external clock generator must be connected to this pin. In this case, a 54-MHz clock is needed for PAL or NTSC 601, a 49.09-MHz clock is needed for NTSC square pixel, and a 59-MHz clock is needed for PAL square pixel.

- Video DAC stage clocks

The video DAC stage uses one distinct clock: The DSS_TV_FCLK. The video data are latched on the positive edge of the DSS_TV_FCLK clock.

7.3.1.2 Resets

7.3.1.2.1 Hardware Reset

The display subsystem receives its reset signal DSS_RST (the reset signal of the display subsystem [DSS] power domain) from the PRCM module.

7.3.1.2.2 Software Reset

The display subsystem can receive a software reset propagated through all of the submodules and used to initialize the display subsystem. To apply the reset, write to the DSS.DSS_SYSCONFIG[1] SOFTRESET bit (1: Reset; 0: Normal). The DSS.DSS_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1.

NOTE: The display controller, the DSI protocol engine, and the RFBI modules also have their own software reset functionality. To access this reset, access the DSS.DISPC_SYSCONFIG[1] SOFTRESET bit for the display controller, the DSS.DSI_SYSCONFIG[1] SOFTRESET bit for the DSI protocol engine, and the DSS.RFBI_SYSCONFIG[1] SOFTRESET bit for the RFBI module.

To properly reset these modules, 0x2 is the only valid value to write to these registers.

CAUTION

All the interface and functional clocks, even for the TV output, must be provided to the display subsystem to update the RESETDONE status bit correctly.

7.3.1.3 Power Domain

The display subsystem modules are on the display subsystem (DSS) power domain and on the VDD2 voltage domain, except for the video DAC stage, which are on the analog vdda_dac voltage domain.

7.3.1.4 Power Management

7.3.1.4.1 Clock Activity Mode

The display controller clocks can be configured in one of the following clock activity modes:

- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSI protocol engine clocks can be configured in one of the following clock activity modes:

- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSS power domain clock activity status is logged in the PRCM.CM_CLKSTST_DSS[0] CLKACTIVITY_DSS status bit. When set to 0, there is no domain clock activity. When set to 1, the DSS power domain clock is active.

-
- NOTE:** The display subsystem interface clock can be dependent on the DSS power domain state. This is configured with PRCM.CM_AUTOIDLE_DSS[0] AUTO_DSS bit:
- When the AUTO_DSS bit is set to 0 (reset value): The display subsystem interface clock is not related to the DSS power domain state transition.
 - When the AUTO_DSS bit is set to 1: The display subsystem interface clock is automatically enabled or disabled along with the DSS power domain state transition.
-

7.3.1.4.2 *Autoidle Mode*

The RFBI, display controller, DSI protocol engine, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DSI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the DSI protocol engine
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled; 0: Functional clocks gated disabled) for the display controller

NOTE: All the bits listed above (except for the FUNCGATED bit) are set to 1 by default. It is highly recommended to set all the bits to 1 to save power.

7.3.1.4.3 *Idle Mode*

The display controller, DSI protocol engine, and RFBI can be configured into one of the following acknowledgment modes:

- Force-idle mode: The module immediately enters the idle state on receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for RFBI.
- No-idle mode: The module never enters the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for RFBI.
- Smart-idle mode:
 - Display controller: After receiving a low-power-mode request from the PRCM module, the display controller module enters the idle state when all the following conditions are satisfied:
 - All asserted output interrupts are acknowledged (no interrupt pending).
 - The display controller does not use anymore the L4 interface clock (DSS_L4_ICLK).
 - DSI protocol engine: After receiving a low-power-mode request from the PRCM module, the DSI protocol engine enters the idle state when all the following conditions are satisfied:
 - All asserted output interrupts are acknowledged (no interrupt pending).
 - The DSI protocol engine does not use the L4 interface clock (DSS_L4_ICLK) anymore.
 - The SCP and PWR transactions are complete.
 - No data remains in the TX FIFO (data waiting in the FIFO to be sent to the peripheral).

To configure the display subsystem in smart-idle mode, set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for RFBI.

Once the idle handshake protocol is over:

- The DSS L4 interface clock (DSS_L4_ICLK) can be shutdown at any time.
- Any transaction on the L4 configuration port is ignored.

7.3.1.4.4 Wake-Up Mode

The Display Controller (DISPC) supports the wake-up protocol. The mode is selected by programming the appropriate value in the DSS.DISPC_SYSCONFIG[2] ENWAKEUP bit. The wake-up signal is asserted when the DISPC is in idle mode and when anyone of the following events occur:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- The current pixel is the last pixel displayed on the LCD panel if it is not the last frame.
- The current pixel is the last pixel displayed on the digital panel if it is not the last frame.

If software users set the DSS.DISPC_CONFIG[17] FIFOFILLING bit, when one of the active pipe reaches the low threshold and should refill the FIFO for the current frame, the other pipes also refill their own FIFOs, even if the low threshold has not been reached. This is used to improve the probability of increasing the time when there is no access to the L3 interconnect (MStandby asserted, affects power savings).

Once the wake-up signal is asserted, the WAKEUP interrupt request is generated. The wake-up signal is deasserted when the idle request is no longer activated.

7.3.1.4.5 Standby Mode

As part of the system-wide power-management scheme, the display controller can enter standby mode. To configure the display controller, write the DSS.DISPC_SYSCONFIG[13:12] MIDDLEMODE bit field (00: Forced standby; 01: No standby; 10: Smart standby) in one of the following standby modes:

- Forced standby mode (default mode): The module enters standby mode when the module is disabled.
- No standby mode: The module never enters standby mode.
- Smart standby mode: The module enters standby state when the DISPC module is disabled or when all the three following events occur:
 - Graphics pipe is disabled or graphics pipe is enabled but data fetch completed for graphics window, or graphics pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
 - Video1 pipe is disabled or video1 pipe is enabled but data fetch completed for video1 window, or video1 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
 - Video2 pipe is disabled or video2 pipe is enabled but data fetch completed for video2 window, or video2 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.

When in standby mode, the display controller does not generate transactions on the L3 master port. Standby is active when the PRCM module confirms this mode.

The display subsystem standby mode activity can be monitored with the PRCM.CM_IDLEST_DSS[0] ST_DSS status register. When this register is read to 0, the display subsystem is accessible and the interface clock running; when it is read to 1, the display subsystem is in standby mode.

7.3.1.4.5.1 Conditions to Exit Standby Mode

The following conditions allow the subsystem to exit standby mode:

- Forced standby mode: Standby mode is exited when the display controller is enabled.
- Smart standby mode: Standby mode is exited when any one of the following events occurs:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and number of data bytes in FIFO is less than the low threshold programmed value.

7.3.1.4.5.2 Standby Transition Dependency

The sleep transition of the DSS power domain can be dependent or not with respect to MPU domain. This is configured by PRCM.CM_SLEEPDEP_DSS[1] EN_MPU bit:

- When the EN_MPU bit is set to 0 (reset value): The DSS power domain sleep dependency with the MPU power domain is disabled. The DSS power domain will not enter idle unless the MPU power has previously entered idle.
- When the EN_MPU bit is set to 1: The DSS power domain sleep dependency with the MPU power domain is enabled. The DSS power domain will enter idle regardless of the power domain state of the MPU.

The sleep transition of the DSS power domain may, or may not depend on the IVA2.2 domain, depending on the configuration of the PRCM.CM_SLEEPDEP_DSS[2] EN_IVA2 bit:

- When the EN_IVA2 bit is set to 0 (reset value): The DSS power domain sleep dependency on the IVA2.2 power domain is disabled.
- When the EN_IVA2 bit is set to 1: The DSS power domain sleep dependency on the IVA2.2 power domain is enabled.

7.3.1.4.5.3 Standby Procedure Description

When the display subsystem initiates a standby procedure, it also initiates an standby/wait handshake protocol with the PRCM module that lets the PRCM cut the display subsystem clocks. Depending on the PRCM setting, two modes are available:

- Manual mode
 - DSS1_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit is set to 0 and the display subsystem is in standby mode.
 - DSS2_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit is set to 0 and the display subsystem is in standby mode.
 - DSS_L3_ICLK and DSS_L4_ICLK are controlled together. They are shut down when the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit is set to 0 and the display subsystem is in standby mode.

CAUTION

Do not stop DSS1_ALWON_FCLK, or DSS2_ALWON_FCLK clock (if used) if the display subsystem is not disabled.

CAUTION

DSS_TV_FCLK does not depend on the display subsystem standby state. Ensure correct clock management for DSS_TV_FCLK.

The clocks are reactivated when the related bits are set to 1 and the display subsystem exits from standby. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- Hardware- or software-supervised mode

The DSS-power state-transition between active and inactive states can be either hardware or software supervised. This is programmed with the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS bit field:

- When the CLKTRCTRL_DSS bit field is set to 0x0 (reset value), the automatic transition is disabled
- When the CLKTRCTRL_DSS bit field is set to 0x1, the software-supervised sleep transition is started on the DSS power domain.
- When the CLKTRCTRL_DSS bit field is set to 0x2, the software-supervised wake-up transition is started on the DSS power domain.
- When the CLKTRCTRL_DSS bit field is set to 0x3, the automatic transition is enabled. Any transition on the DSS power domain is supervised by the hardware.

7.3.1.4.5.4 Display Subsystem Standby Mode, Power-Saving Use Cases

- Setup
 - Set the display subsystem in smart standby mode.
 - Manually enable DSS_L3_ICLK and DSS_L4_ICLK.
 - Manually enable DSS1_ALWON_FCLK or DSS2_ALWON_FCLK.
 - Manually enable DSS_TV_FCLK if the video encoder is used.
 - Set the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS bit field to 0x3 (autocontrol mode supervised by hardware).
- Shut down the display subsystem.
 - Disable the display subsystem.
 - Manually disable DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, DSS_TV_FCLK, DSS_L3_ICLK, and DSS_L4_ICLK.

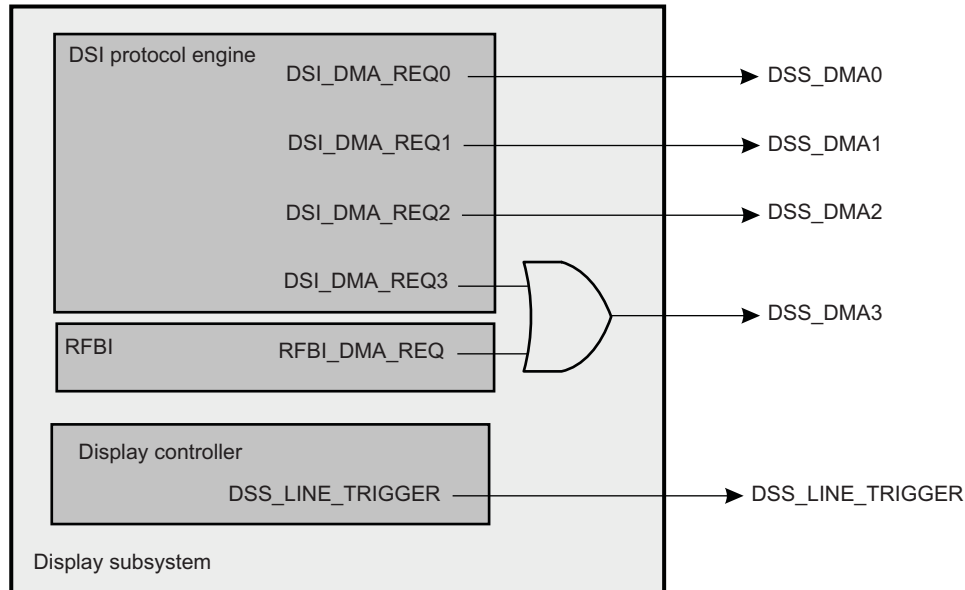

For more details on low-power programming settings, see [Section 7.6.2](#).

7.3.2 Hardware Requests

7.3.2.1 DMA Requests

The display controller, the DSI protocol engine, and the RFBI generate some DMA requests to the sDMA. Figure 7-64 details the DMA tree.

Figure 7-64. Display Subsystem DMA Tree

dss-159

Table 7-21. DSS DMA Requests Description

DMA Request Name	DSS Module	Mapping	Description
DSS_LINE_TRIGGER	DISPC	S_DMA_5	See Section 7.3.2.1.1
DSI_DMA_REQ0	DSI protocol engine	S_DMA_71	See Section 7.3.2.1.2
DSI_DMA_REQ1	DSI protocol engine	S_DMA_72	See Section 7.3.2.1.2
DSI_DMA_REQ2	DSI protocol engine	S_DMA_73	See Section 7.3.2.1.2
DSI_DMA_REQ3	DSI protocol engine	S_DMA_74	See Section 7.3.2.1.2
RFBI_DMA_REQ	RFBI	S_DMA_74	See Section 7.3.2.1.3

NOTE: The DMA requests from the RFBI module (RFBI_DMA_REQ) and the DSI protocol engine (DSI_DMA_REQ3) are merged on line DSS_DMA3. The software must only use DSS_DMA3 on one module at a time (RFBI or DSI protocol engine).

7.3.2.1.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS_LINE_TRIGGER) is connected to the sDMA by the sDMA controller (S_DMA_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This request is related to an interrupt event described in Section 7.3.2.2, *Interrupt Requests*. This allows the sDMA channel to be synchronized with the display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS_LINE_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC_LINE_NUMBER[10:0] LINENUMBER bit field.

7.3.2.1.2 DSI Protocol Engine DMA Request

The DSI DMA requests are used to allow automatic transfer by the sDMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported.

7.3.2.1.3 RFBI DMA Request

The RFBI_DMA_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

7.3.2.2 Interrupt Requests

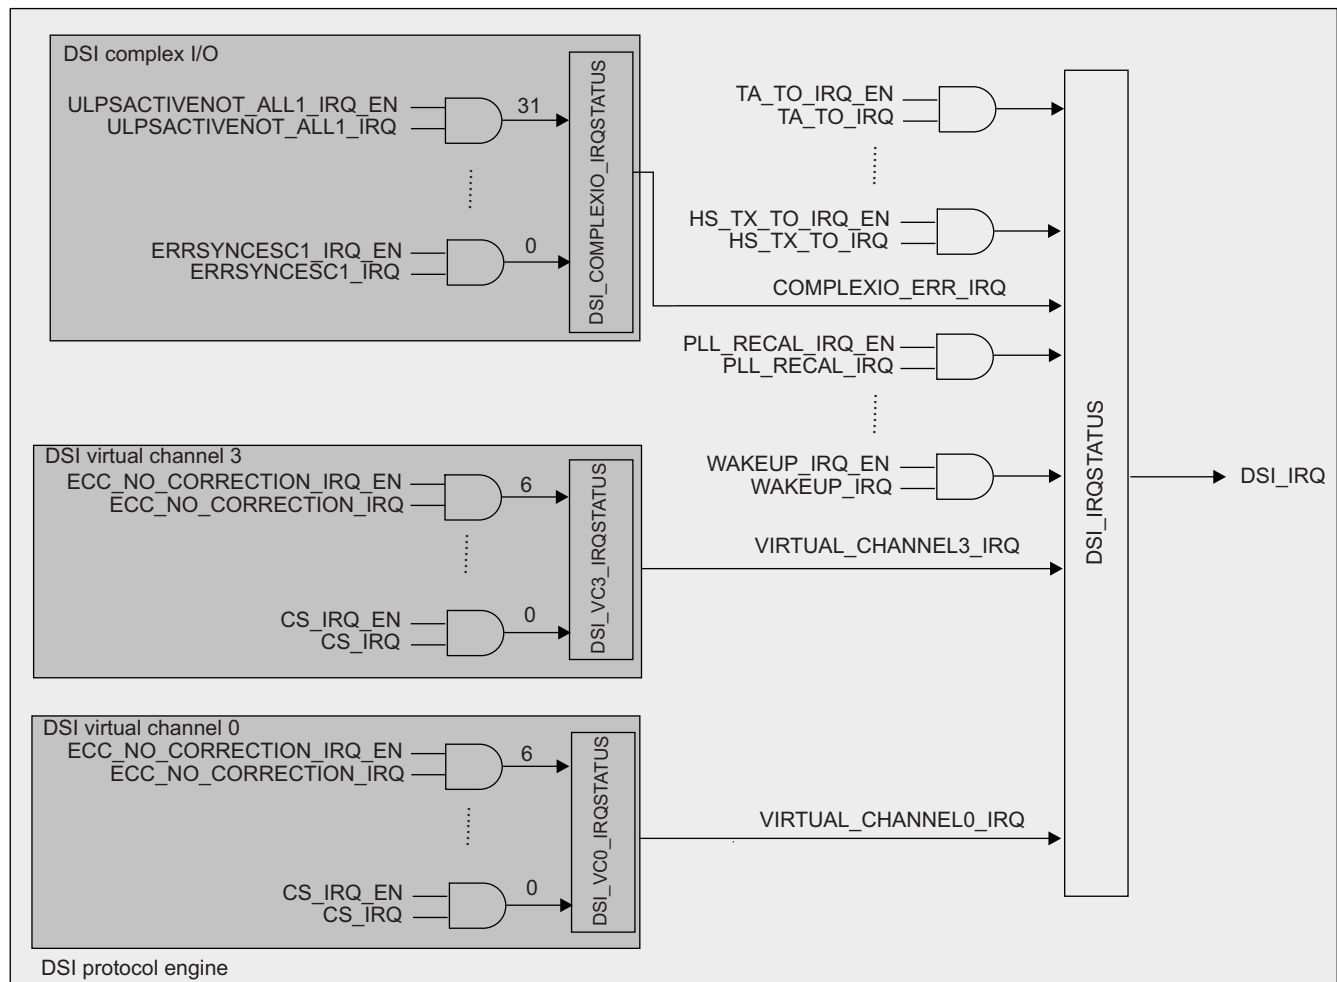

The DSI protocol engine, the DSI complex I/O (DSI_IRQ), and the display controller (DISPC_IRQ) generate one interrupt request each. The DSI_IRQ and DISPC_IRQ lines are merged together in a single interrupt line.

One interrupt line (DSS_IRQ) is connected to two interrupt controllers:

- MPU interrupt controller (M_IRQ_25 input line)
- IVA interrupt handler (IVA2_IRQ[13] input line)

Figure 7-65 shows the interrupt tree for the DSI protocol engine and DSI complex I/O in detail.

Figure 7-65. DSI Interrupt Tree

dss-160

Figure 7-66 details the interrupt tree for the DISPC and the display subsystem.

Figure 7-66. DISPC and DSS Interrupts Tree

dss-161

7.3.2.2.1 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the `DSS.DISPC_IRQENABLE` register.

To check when a particular interrupt event occurs and to reset a particular event, the `DSS.DISPC_IRQSTATUS` register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See [Section 7.7, Display Subsystem Register Manual](#), for more information on checking and clearing interrupt events.

[Table 7-22](#) lists the display subsystem interrupt events.

Table 7-22. Display Subsystem Interrupts

Interrupt Name	Description
FRAMEDONE	Active frame is complete and LCD output is disabled.
VSYNC	VSYNC interrupt occurred at the end of the frame.
EVSYNC_EVEN ⁽¹⁾	EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.)
EVSYNC_ODD ⁽¹⁾	EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.)
ACBIASCOUNTSTATUS	The ac-bias transition counter decremented to 0.
PROGRAMMEDLINENUMBER	The LCD reached the user-programmed line number.
GFXFIFOUNDERFLOW	The input graphics FIFO goes underflow.
GFXENDWINDOW	The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen.
PALETTEGAMMALOADING	The palette/gamma table is loaded.
OCPERROR	L3 interconnect sent SResp = ERR.
VID1FIFOUNDERFLOW	The input video1 FIFO goes underflow.

⁽¹⁾ EVYNC interrupts (EVSYNC_EVEN and EVSYNC_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

Table 7-22. Display Subsystem Interrupts (continued)

Interrupt Name	Description
VID1ENDWINDOW	The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen.
VID2FIFOUNDERFLOW	The input video2 FIFO goes underflow.
VID2ENDWINDOW	The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen.
SYNCLOST	Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output).
SYNCLOSTDIGITAL	Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly.
WAKEUP	Occurs when the wakeup signal is asserted

NOTE: To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC_CONTROL[0] LCDENABLE (LCD: SYNCLOST interrupt) or DSS.DISPC_CONTROL[1] DIGITALENABLE (TV: SYNCLOSTDIGITAL interrupt) bits.

Check the interrupts.

LCD: Verify that a FRAMEDONE interrupt occurs.

TV : Verify that EVSYNC_EVEN or EVSYNC_ODD interrupts occur.

2. Set the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

NOTE: The SYNCLOSTDIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), must not be considered.

After the first VSYNC pulse signal, the SYNCLOSTDIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit; then the SYNCLOSTDIGITAL interrupt can be enabled by setting the DSS.DISPC_IRQENABLE[15] SYNCLOSTDIGITAL bit.

7.3.2.2 DSI Interrupt Request

The DSI protocol engine requires a single interrupt line, DSI_IRQ. The DSS.DSI_IRQSTATUS register indicates the general interrupt events. See [Table 7-23](#). Each VC and complex I/O has a dedicated interrupt register: DSS.DSI_VCn_IRQSTATUS and DSS.DSI_COMPLEXIO_IRQSTATUS respectively. See [Table 7-24](#) and [Table 7-25](#).

[Table 7-23](#) indicates the DSI global interrupt events.

Table 7-23. DSI Global Interrupts

Interrupt Name	Description
RESYNCHRONIZATION_IRQ	Resynchronization in video mode
TA_TO_IRQ	Turn-around timer expired
LDO_POWER_GOOD_IRQ	Signal LDOPWRGOOD from the DSI_PHY changes its state for the supply VDDALDODSIPLL from up to down or down to up.
SYNC_LOST_IRQ	Synchronization with video mode port is lost (video mode only)
ACK_TRIGGER_IRQ	Acknowledge trigger is received
TE_TRIGGER_IRQ	Tearing effect trigger is received
WAKEUP_IRQ	Occurs when the SWakeUp signal is asserted
HS_TX_TO_IRQ	High speed TX Time-out Interrupt

Table 7-23. DSI Global Interrupts (continued)

Interrupt Name	Description
LP_RX_TO_IRQ	Low speed RX Time-out Interrupt
COMPLEXIO_ERR_IRQ	Error signaling from complex I/O: The interrupt is triggered when any error is received from the complex I/O (events are defined in DSI_COMPLEXIO_IRQSTATUS).
PLL_RECAL_IRQ	PLL recal event (assertion of DSIRecal signal from the DSI PLL Control module)
PLL_UNLOCK_IRQ	PLL unlock event (deassertion of DSILock signal from the DSI PLL Control module)
PLL_LOCK_IRQ	PLL lock event (assertion of DSILock signal from the DSI PLL Control module)
VIRTUAL_CHANNEL3_IRQ	Virtual channel #3 Error signaling from DSI Virtual Channel3: The interrupt is triggered when an error is received from DSI Virtual Channel3 (events are defined in DSI_VC3_IRQENABLE).
VIRTUAL_CHANNEL2_IRQ	Virtual channel #2 Error signaling from DSI Virtual Channel2: The interrupt is triggered when an error is received from DSI Virtual Channel2 (events are defined in DSI_VC2_IRQENABLE).
VIRTUAL_CHANNEL1_IRQ	Virtual channel #1 Error signaling from DSI Virtual Channel1: The interrupt is triggered when an error is received from DSI Virtual Channel1 (events are defined in DSI_VC1_IRQENABLE).
VIRTUAL_CHANNEL0_IRQ	Virtual channel #0 Error signaling from DSI Virtual Channel0: The interrupt is triggered when an error is received from DSI Virtual Channel0 (events are defined in DSI_VC0_IRQENABLE).

[Table 7-24](#) indicates the DSI complex I/O interrupt events.

Table 7-24. DSI Complex I/O Interrupts

Interrupt Name	Description
ULPSActiveNot_ALL0_IRQ	All signals ULPSActiveNOT are 0
ULPSActiveNot_ALL1_IRQ	All the ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high
STATEULPS3_IRQ	Lane #3 in ultralow-power state
STATEULPS2_IRQ	Lane #2 in ultralow-power state
STATEULPS1_IRQ	Lane #1 in ultralow-power state
ERRCONTROL3_IRQ	Control error for lane #3
ERRCONTROL2_IRQ	Control error for lane #2
ERRCONTROL1_IRQ	Control error for lane #1
ERRESC3_IRQ	Escape entry error for lane #3(edge trigger interrupt)
ERRESC2_IRQ	Escape entry error for lane #2 (edge trigger interrupt)
ERRESC1_IRQ	Escape entry error for lane #1 (edge trigger interrupt)
ERRCONTENTIONLP1_1_IRQ	Contention LP1 error for lane #1
ERRCONTENTIONLP0_1_IRQ	Contention LP0 error for lane #1
ERRCONTENTIONLP1_2_IRQ	Contention LP1 error for lane #2
ERRCONTENTIONLP0_2_IRQ	Contention LP0 error for lane #2
ERRCONTENTIONLP1_3_IRQ	Contention LP1 error for lane #3
ERRCONTENTIONLP0_3_IRQ	Contention LP0 error for lane #3
ERRSYNCESC3_IRQ	Low power Data transmission synchronization error for lane #3
ERRSYNCESC2_IRQ	Low power Data transmission synchronization error for lane #2
ERRSYNCESC1_IRQ	Low power Data transmission synchronization error for lane #1

NOTE: The error contention signals for DX and DY signals of each lane are ORed together.

Table 7-25 indicates the DSI VCs interrupt events

Table 7-25. DSI Virtual Channel Interrupts

Interrupt Name	Description
ECC_CORRECTION_IRQ	Indicates if a 1-bit error correction occurred using the ECC
PACKET_SENT_IRQ	Indicates that a packet has been sent. It is used when BTA manual mode is used
CS_IRQ	Virtual channel - Check-Sum of the payload mismatch detection
FIFO_RX_OVF_IRQ	RX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the DSI link has overflowed
FIFO_TX_OVF_IRQ	TX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the L4 interconnect slave port has overflowed
BTA_IRQ	Bus turnaround is received from the peripheral (the VC ID used for the last BTA request transfer to the peripheral is used to determine which VC is used to flag the interrupt)
ECC_NO_CORRECTION_IRQ	ECC error (short and long packets). No correction of the header because of more than 1-bit error
FIFO_TX_UDF_IRQ	TX FIFO underflow. The FIFO used on the slave port for buffering the data received on the L4 interconnect port has under-flowed in the middle of a packet transfer

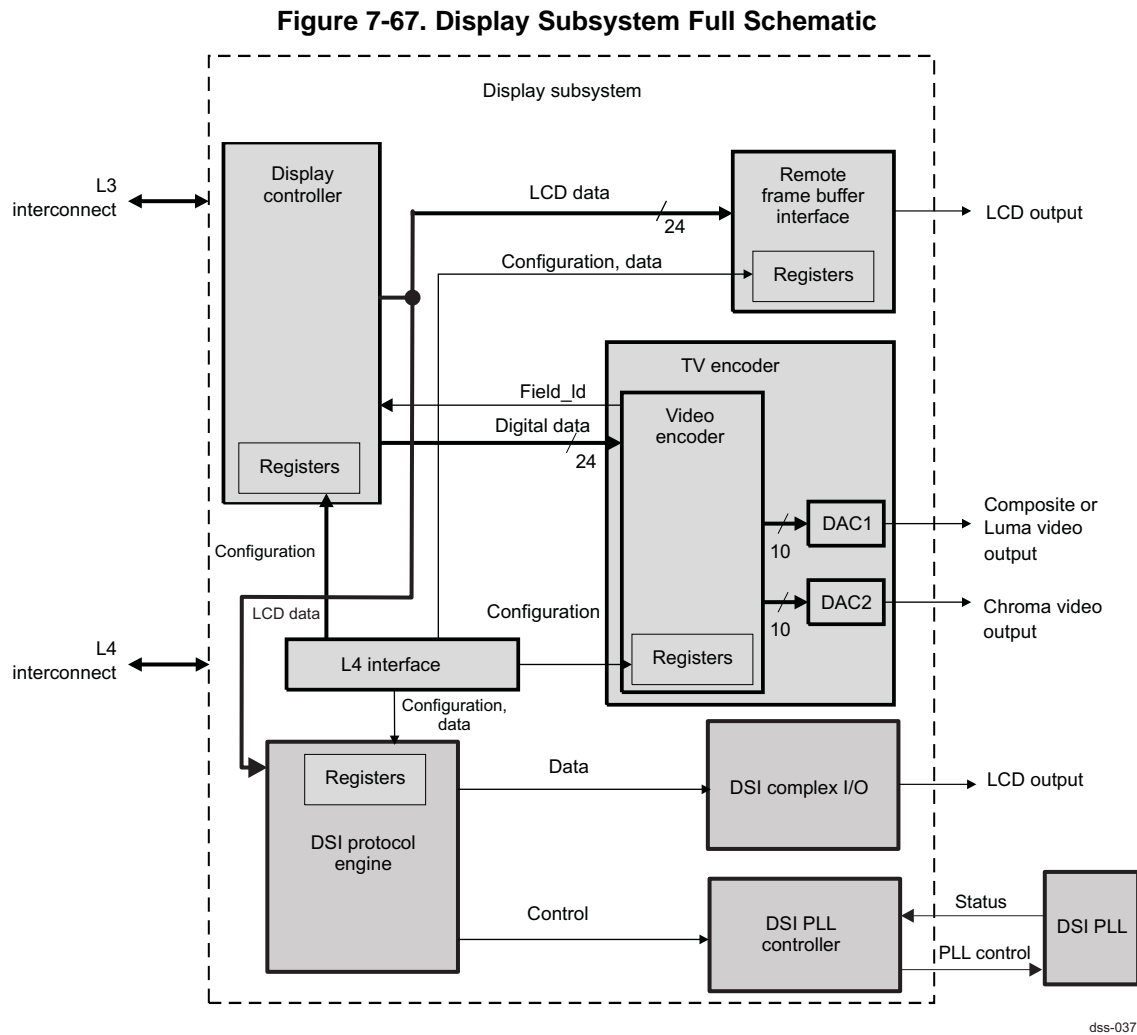

7.4 Display Subsystem Functional Description

This section describes the functions of the LCD and TV display supports by describing the following modules: display controller, DSI protocol engine, DSI PLL controller, DSI complex I/O, RFBI and video encoder.

The functions of the display controller are common to both LCD and TV data paths; the RFBI are LCD-specific; and the video encoder functions are specific to the TV set.

7.4.1 Block Diagram

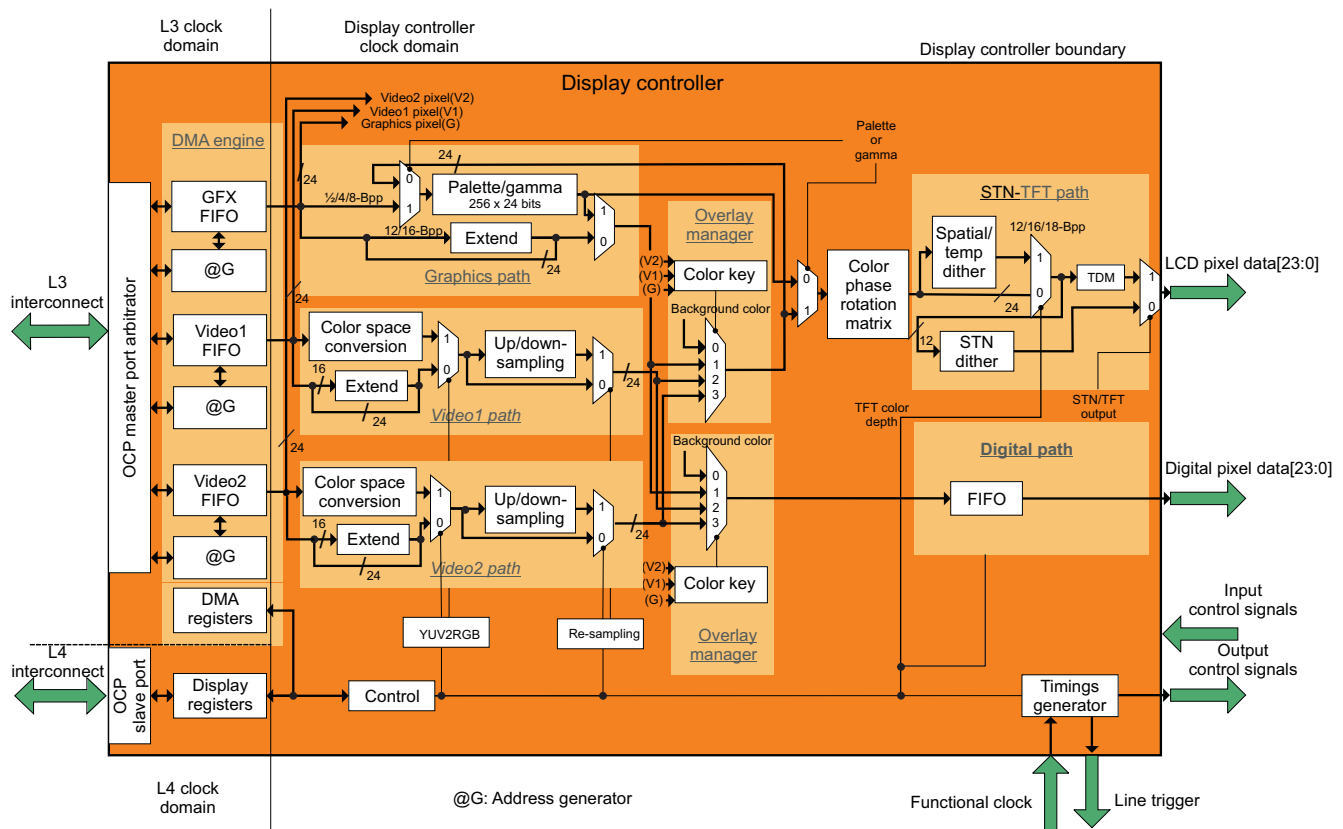

Figure 7-67 is a schematic of the display subsystem.

7.4.2 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 7-68).

Figure 7-68. Display Controller Architecture Overview

dss-038

Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

7.4.2.1 Display Modes

7.4.2.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

7.4.2.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

7.4.2.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

7.4.2.2.1 Graphics Memory Format

The supported formats for the graphics layer are CLUT bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (little endian)

- BITMAP 1-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 1-BPP data memory organization (CLUT) (big endian)

- BITMAP 1-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 2-BPP data memory organization (CLUT) (little endian)

- BITMAP 2-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 2-BPP data memory organization (CLUT) (big endian)

- BITMAP 2-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 4-BPP data memory organization (CLUT) (little endian)

- BITMAP 4-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 4-BPP data memory organization (CLUT) (big endian)

- BITMAP 4-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 8-BPP data memory organization (CLUT) (little endian)

- BITMAP 8-BPP data memory organization (CLUT) (big endian)

- RGB 12-BPP data memory organization (little endian)

- RGB 12-BPP data memory organization (big endian)

- RGB 16-BPP data memory organization (little endian)

- RGB 16-BPP data memory organization (big endian)

- ARGB 16-BPP data memory organization (little endian)

- ARGB 16-BPP data memory organization (big endian)

- RGB 24-BPP data memory organization (little or big endian)

- ARGB 32-BPP data memory organization (little or big endian)

- RGBA 32-BPP data memory organization (little or big endian)

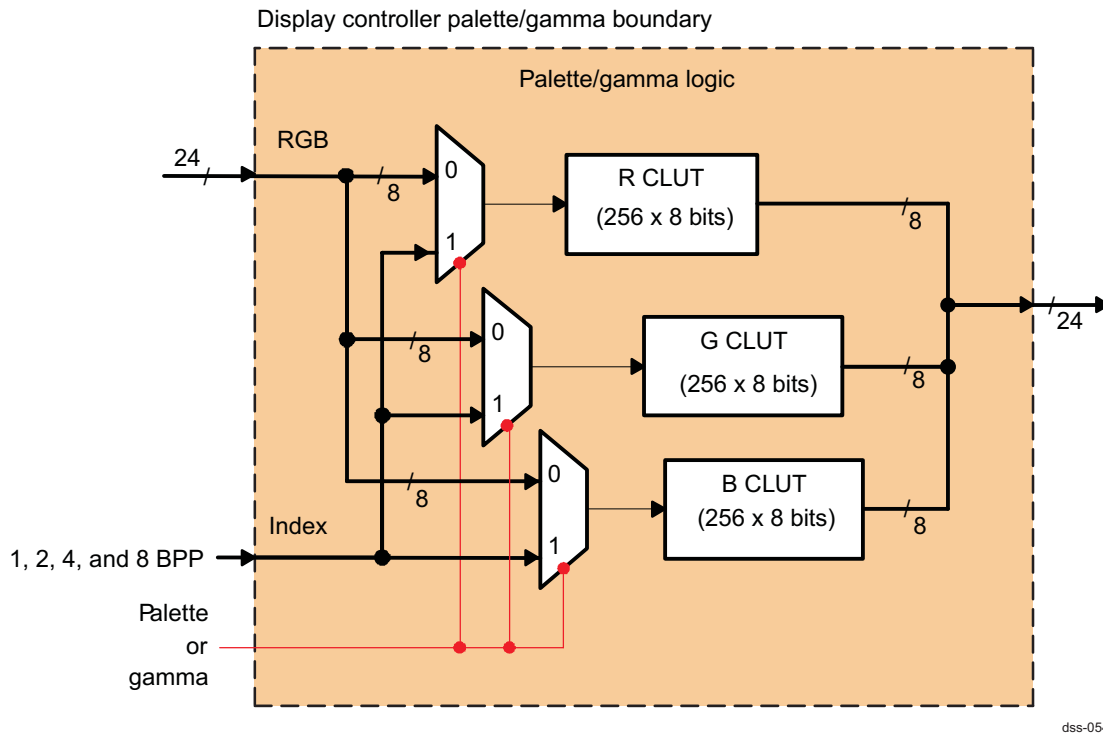

- RGB 24-BPP packet data memory organization (little or big endian)

7.4.2.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. [Figure 7-69](#) shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

Figure 7-69. Palette/Gamma Correction Architecture

7.4.2.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). The format of one of the palette values in the memory is as follows:

- 24-BPP Data Memory Organization (Little Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								R								G								B							

In monochrome mode, only one 8-bit value is present.

- 24-BPP Data Memory Organization (Little Endian or Nibble)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								Unused								Unused								Gray							

After passing through the palette, 256 gray scales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 gray scales and 3375 colors.

- Passive matrix technology
 - The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology

The palette is bypassed in 12, 16, and 24 BPP, allowing up to $2^{24} = 16,777,216$ colors to be displayed.

7.4.2.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component. The format of one of the gamma curve values in the memory is as follows:

- 24-BPP Data Memory Organization (Little or Big Endian)

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Unused								Gamma-R								Gamma-G								Gamma-B							

7.4.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

dss-T055

- If replication logic is ON:

dss-T056

- If replication logic is OFF:

dss-T057

7.4.2.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV4:2:2 pixels.

7.4.2.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

- RGB 12-BPP data memory organization (little endian)

- RGB 12-BPP data memory organization (big endian)

- RGB 16-BPP data memory organization (little endian)

- RGB 16-BPP data memory organization (big endian)

- ARGB 16-BPP data memory organization (little endian + video 2 channel only)

- ARGB 16-BPP data memory organization (big endian + video 2 channel only)

- RGB 24-BPP data memory organization (little or big endian)

- RGB 24-BPP packet data memory organization (little or big endian)

- ARGB 32-BPP data memory organization (little or big endian + video 2 channel only)

- RGBA 32-BPP data memory organization (little or big endian + video 2 channel only)

- UYVY 4:2:2 data memory organization (little endian)

- UYVY 4:2:2 data memory organization (big endian)

- YUV2 4:2:2 data memory organization (little endian)

- YUV2 4:2:2 data memory organization (big endian)

7.4.2.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. Figure 7-70 and Figure 7-71 detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

Figure 7-70. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)

Figure 7-71. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)

The interpolation of the missing chrominance component is given by the equation in Figure 7-72.

Figure 7-72. Interpolation of the Missing Chrominance Component

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from

the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.

- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. Users set the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV4:2:2 format is converted into YUV4:4:4. The YUV4:2:2-to-YUV4:4:4 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16:235] and [16:240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 7-73](#) gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

Figure 7-73. YCbCr to RGB Registers (VIDFULLRANGE = 0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 7-74](#) gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

Figure 7-74. YCbCr to RGB Registers (VIDFULLRANGE = 1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

[Figure 7-75](#) describes the computation for the calculation of the R component. The same computation applies for the G and B components:

Figure 7-75. Color Space Conversion Macro-Architecture

dss-065

7.4.2.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

7.4.2.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV4:2:2

(RGB12 and all the alpha formats like ARGB and RGBA are not supported)

Users must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently (R, G, and B).

For the horizontal up/downsampling, the equation is R component with five taps):

$$R_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E066

(7)

For the vertical up/downsampling, the equation is R component with three taps):

$$R_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \quad \text{dss-E067} \quad (8)$$

For the vertical up/downsampling, the equation is R component with five taps):

$$R_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7 \quad \text{dss-E068} \quad (9)$$

R_{out}: R component output

C_i(Φ)
dss-E069 : FIR filter coefficients

R_{in}: R component input

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

NOTE: The coefficients *C_i*() depend on the phase between input and output pixels.

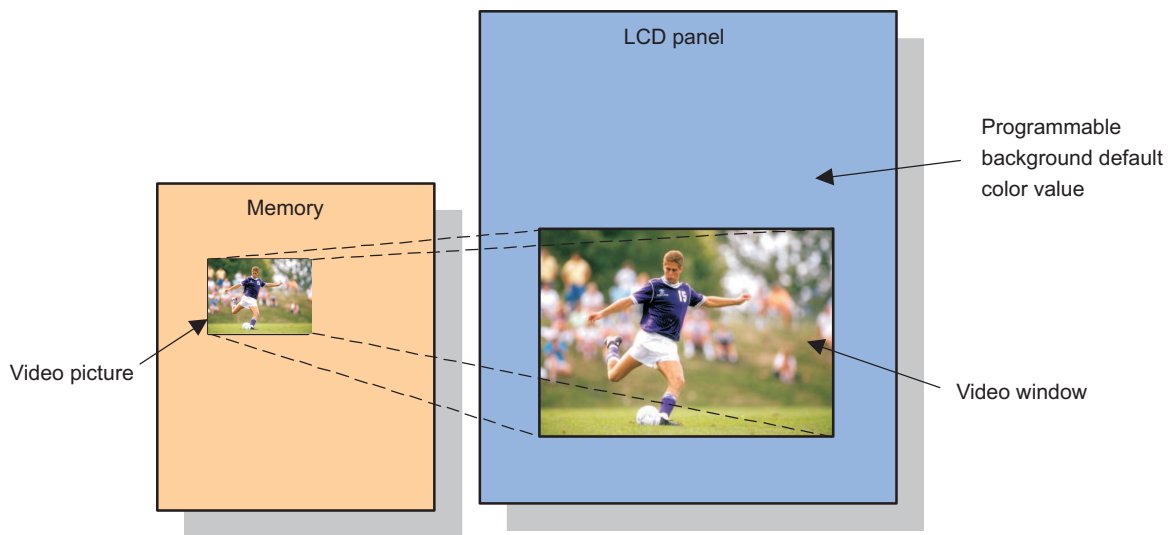

NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels:

`DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1`

`DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX 4 and even`

Figure 7-76 shows an example of video upsampling.

Figure 7-76. Video Upsampling

dss-070

Filter Description

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is $is/2$. The downsampling ratio using 5-tap configuration is $is/4$. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 7-77 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

Figure 7-77. Resampling Macro-Architecture (3-Coefficient Processing)

dss-071

To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with [Table 7-26](#) and [Table 7-27](#).

Ratio V when performing a vertical down-sampling only

$$h_ratio = \frac{DISPC_SIZE_LCD.PPL}{DISPC_VID_SIZE.VidSizeX}$$

$$v_ratio = \frac{DISPC_VID_PICTURE_SIZE.VidOrgSizeY}{DISPC_VID_SIZE.VidSizeY}$$

$$Ratio = \frac{v_ratio}{2 \times h_ratio} \quad \text{If } 1 < v_ratio \leq 2$$

$$Ratio = \max\left(\frac{v_ratio}{2 \times h_ratio}, \frac{v_ratio - 2}{2 \times (h_ratio - 1)}\right) \quad \text{If } 2 < v_ratio \leq 4$$

dss_swpu108-E135

NOTE: For frequency ratio calculation on the TV output, it is correct to replace [DISPC_SIZE_LCD](#) with [DISPC_SIZE_DIG](#).
When the down-sampling ratio is below 0.5, it is not possible to use a video in full screen.

Ratio H when performing a horizontal down-sampling only

$$Ratio = \frac{DISPC_VID_PICTURE_SIZE.VidOrgSizeX}{DISPC_VID_SIZE.VidSizeX}$$

dss_swpu108-E136

Ratio H+V when performing a horizontal and vertical down-sampling

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

Table 7-26. Functional Clock Frequency Requirement in RGB16 YUV4:2:2—Active Matrix Display

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK	RatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Table 7-27. Functional Clock Frequency Requirement in RGB24—Active Matrix Display

Minimum Functional Clock (MHz)		Horizontal Resampling				
		Off	Up	1:1 – 1:2	1:2 – 1:3	1:3 – 1:4
Vertical Resampling	Off	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	Up	AxPCLK	AxPCLK	2xPCLK	3xPCLK	4xPCLK
	3-tap 1:1 to 1:2	2xPCLK	2xPCLK	4xPCLK	6xPCLK	8xPCLK
	5-tap 1:1 to 1:4	RatioxPCLK	RatioxPCLK	2xRatioxPCLK	2xRatioxPCLK	2xRatioxPCLK

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Use case example:

An input picture of 1024*768 is scaled to an output picture of size of 800*600 and displayed onto a LCD of resolution 1280*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

Ratio V: $h_ratio = 1.6$ and $v_ratio = 1.28$ then Ratio = 0.4

Ratio H: Ratio = 1.28

Ratio H+V: Ratio = $\max(1.28, 0.4) = 1.28$

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from [Table 7-26](#) and [Table 7-27](#), If in RGB16-YUV4:2:2:

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = Ratio * PCLK = 95.36 MHz

If in RGB24,

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = 2 * Ratio * PCLK = 190.72 MHz

In this use case, the pixel format supported is RGB16-YUV4:2:2 in a 5-tap configuration.

7.4.2.4 Overlay Support

CAUTION

Enabling overlay optimization (setting the `DSS.DISPC_CONTROL` [12] `OVERLAYOPTIMIZATION` bit) if no overlay region effectively exists (the `DSS.DISPC_VIDn_ATTRIBUTES` [0] `VIDENABLE` bit is cleared, with $n = 1, 2$) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the `DSS.DISPC_GFX_WINDOW_SKIP`[31:0] `GFXWINDOWSKIP` bit field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see [Figure 7-80](#)).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

7.4.2.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

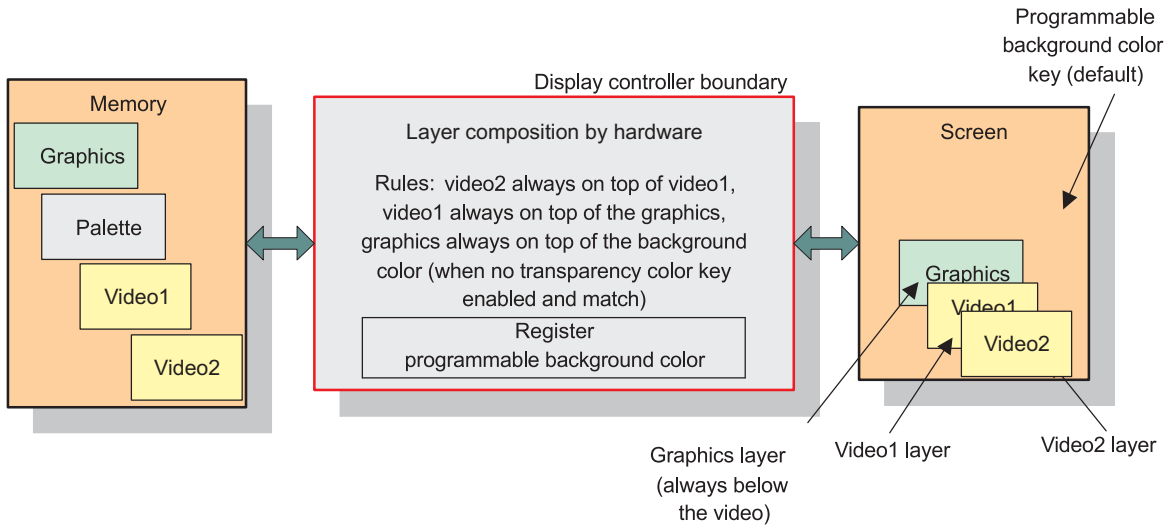

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 7-82](#)).

Figure 7-78. Overlay Manager in Normal Mode

dss-072

Figure 7-79. Display Attributes in Normal Mode

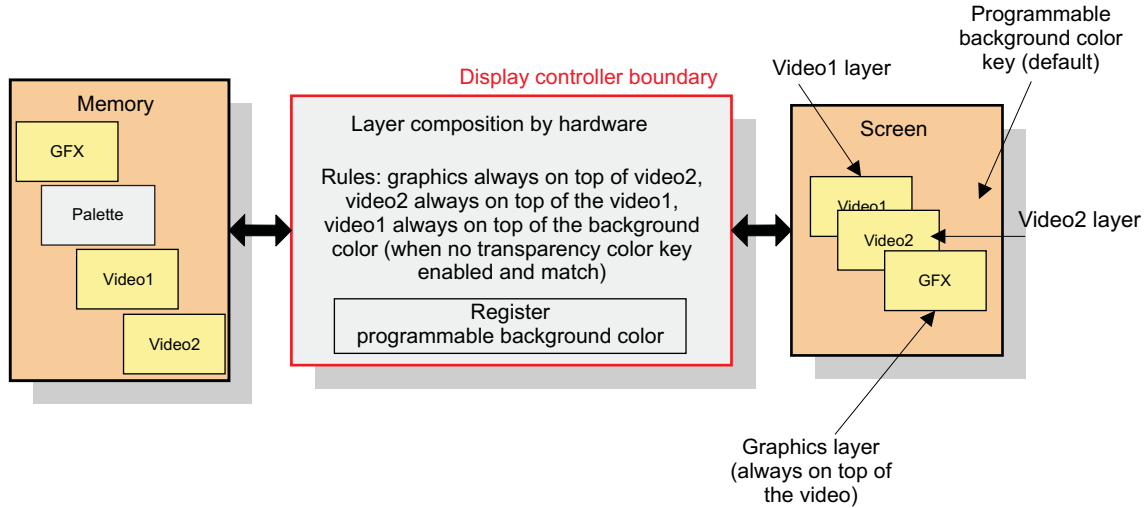

dss-073

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 7-82](#)).

Figure 7-80. Overlay Manager in Alpha Mode

dss-163

Figure 7-81. Display Attributes in Alpha Mode

dss-164

Figure 7-82 shows the alpha blending processing in detail.

- PREMULIPLYALPHA bit = '0' : Source is not pre-multiplied with alpha. Full blending is done in the DISPC.
- PREMULIPLYALPHA bit = '1' : Source is pre-multiplied with alpha. Partial blending is done.

NOTE: The pre-multiplied alpha option is only valid when bit fields DSS.DISPC_GFX_ATTRIBUTES[4:1] GFXFORMAT and DSS.DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT, respectively, are set to ARGB or RGBA formats. Otherwise, the PREMULIPLYALPHA bit fields are ignored by the hardware.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. [Table 7-28](#) details the alpha blending 4-bit values and the corresponding blending percentage.

Table 7-28. Alpha Blending 4-Bit Values

Alpha Blending 4-Bit Value (ARGB-444)	Alpha Blending 8-Bit Value (Converted Value)	% Blending
0x0	0x00	100% (transparent)
0x1	0x11	93.33%
0x2	0x22	86.6%
...
0xE	0xEE	6.6%
0xF	0xFF	0% (opaque)

7.4.2.4.2 Transparency Color Keys

7.4.2.4.2.1 Normal Mode

This section describes the features available in normal mode.

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

NOTE: The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

- Video source transparency color key value:

The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

The video source transparency color key can be used only if the color space conversion and the up/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

To enable the video source transparency color key, set to 0x1 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 7-83](#): The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying

layers are shown.

Figure 7-83. Video Source Transparency Example

dss-074

- Graphics destination transparency color key value:

The graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.

To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 7-84](#): The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

Figure 7-84. Graphics Destination Transparency Example

dss-075

7.4.2.4.2.2 Alpha Mode

This section describes the features available in alpha mode.

Only the graphics source transparency color key is available. The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

7.4.2.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV4:2:2, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV4:2:2 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

7.4.2.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation

- Spatial/temporal dithering
- Passive matrix technology

7.4.2.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in Figure 7-85.

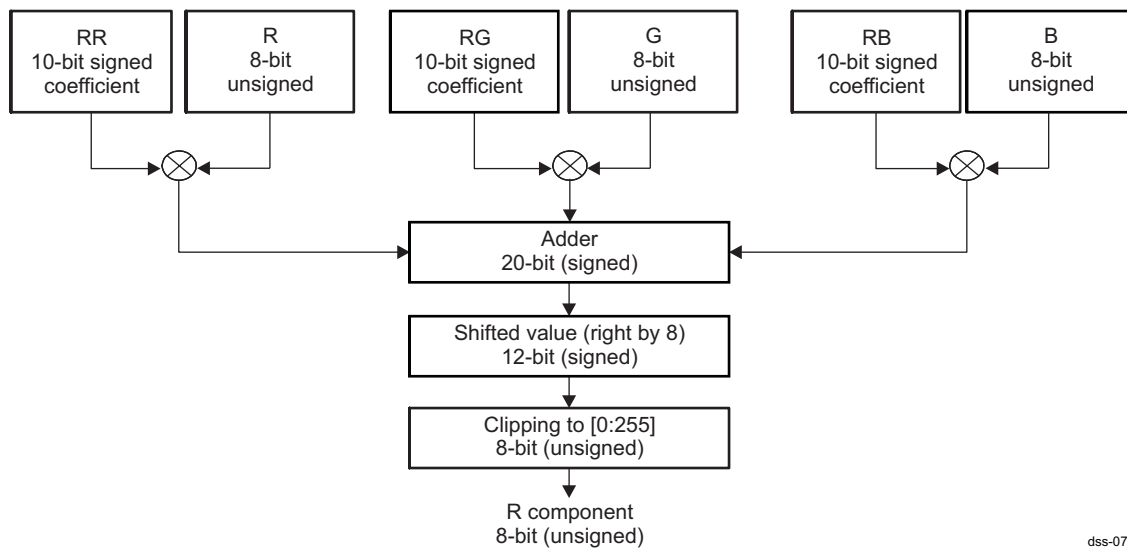

Figure 7-85. Color Phase Rotation Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E076

Figure 7-86 shows the color phase rotation macro-architecture.

Figure 7-86. Color Phase Rotation Macro Architecture

dss-077

7.4.2.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- **Passive Matrix Technology:** The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).

- **Active Matrix Technology:** The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

7.4.2.5.2 **Passive Matrix Display Dithering Logic**

- **Passive matrix technology**
After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data. These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.
- **Active matrix technology**
The passive matrix dithering logic is always bypassed in active displays.

NOTE: If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

7.4.2.5.3 **Passive Matrix Display Output FIFO**

- **Passive matrix technology**
The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.
- **Active matrix technology**
The output FIFO is bypassed in active matrix mode.

7.4.2.5.4 **Multiple Cycle Output Format**

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see [Table 7-29](#)):

- The DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT bit field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC_DATA_CYCLEk (k=0) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC_DATA_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.DISPC_DATA_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

cycle).

Table 7-29. 8-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[7]	R0[7]	G0[7]	B0[7]
Data[6]	R0[6]	G0[6]	B0[6]
Data[5]	R0[5]	G0[5]	B0[5]
Data[4]	R0[4]	G0[4]	B0[4]
Data[3]	R0[3]	G0[3]	B0[3]
Data[2]	R0[2]	G0[2]	B0[2]
Data[1]	R0[1]	G0[1]	B0[1]
Data[0]	R0[0]	G0[0]	B0[0]

7.4.2.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). [Table 7-30](#) lists the maximum width depending on the TAP configuration and the pixel format.

Table 7-30. Maximum Width Allowed

Vertical Tap	Pixel Format	Maximum Width (Pixels)
3	RGB16	2048
	RGB24	
	YUV4:2:2	
5	RGB16	1024
	RGB24	
	YUV4:2:2	

7.4.2.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

7.4.2.8 Rotation

In case of SDRAM buffer, the display controller accesses the encoded pixels in burst, always considering the consecutive data in memory. The rotation engine (VRFB) in the SDRAM scheduler (SDRC) is in charge of translating the addresses from virtual to physical SDRAM addresses (see [Chapter 10, Memory Subsystem](#)).

Rotation using the SMS-VRFB rotation engine is supported for BITMAP8, RGB12 (16-bit container), ARGB16, RGB16, RGB24 (using 32-bit container), ARGB32, RGBA32, and YUV4:2:2 (YUV2 and YUYV). The BITMAP1, BITMAP2, BITMAP4, and RGB24 (using 24-bit container) formats are not supported.

NOTE: For good performance in the L3 interconnect and for SDRAM efficiency, it is highly recommended to use the VRFB rotation engine when possible and not the display subsystem DMA engine to rotate the frame buffer.

A VID DMA optimization is available to optimize the memory traffic (DDR memory) when 90- and 270-degree rotation is required. This optimization consists of reconstructing the RGB16 and YUV line pixels using the cache capability of the DISPC scaler line buffers.

The pixel formats that can take advantage of the reduction in memory traffic are:

- YUV4:2:2
- RGB16 (no reduction is possible for RGB24 packed and unpacked formats)

The benefits of the video DMA optimization, when the feature is enabled, are:

- The L3 interconnect traffic is reduced by a factor of 2x (only for YUV4:2:2 pixel format)
- The DDR memory traffic is reduced by a factor of 2x (for YUV4:2:2 and RGB16 pixel formats)

For more information about the configuration settings for video DMA optimization, see [Section 7.5.3.4.5, Video DMA Optimization](#).

NOTE: The DMA optimization feature must be used only for YUV and RGB16 formats when 90- or 270-degree rotation is required. In all other configurations, the [DISPC_VIDn_ATTRIBUTES\[20\]](#) VIDDMAOPTIMIZATION bit must be kept at reset value (0x0).

7.4.2.9 Multiple Buffer Support

Users update the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

7.4.3 DSI Protocol Engine Functionalities

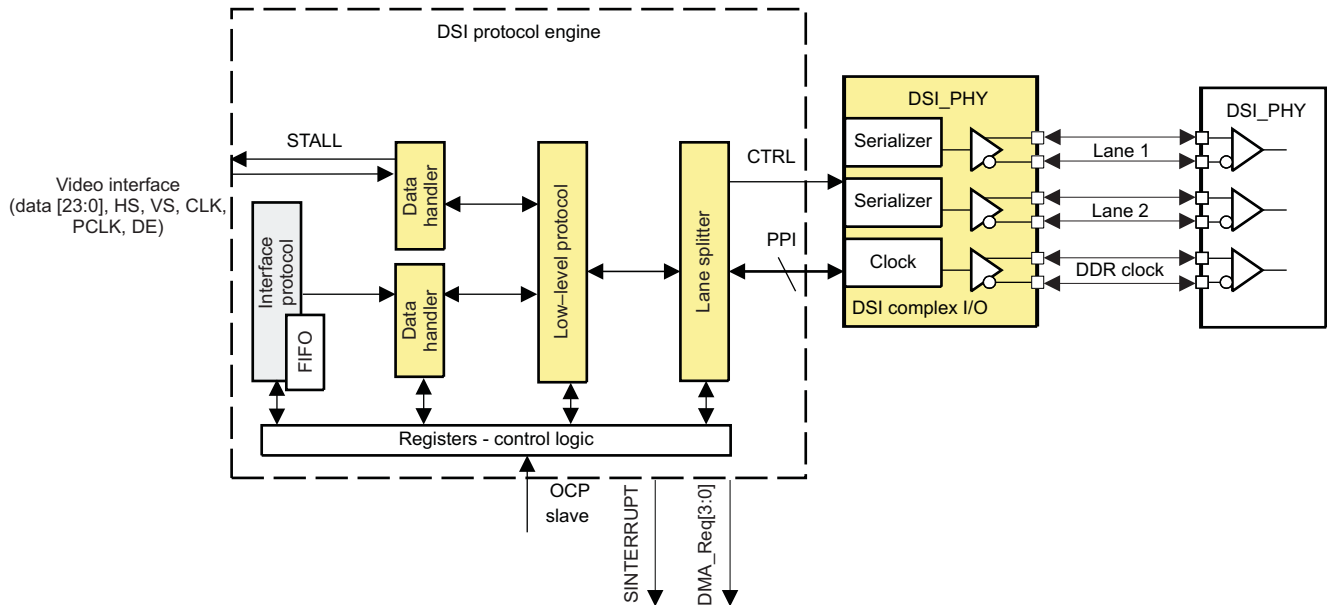

NOTE: Copyright ©2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

The DSI protocol engine integrates DSI interface to the display through the DSI DSI_PHY module, L4 interconnect interface and video interface from the display controller. The DSI DSI_PHY or complex I/O module is detailed in [Section 7.4.5](#). The DSI transmitter (protocol engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL control module detailed in [Section 7.4.4](#). The DSI transmitter port can be used in video mode or/and command mode.

7.4.3.1 DSI Protocol Architecture

The DSI protocol engine receives data from the video port and/or the L4 interconnect slave port, encapsulates them with the VC ID, generates the ECC and check-sum, and splits the data into byte stream to the DSI_PHY to be sent using the low-speed (LS) or high-speed (HS) protocol. The DSI protocol engine receives data and acknowledge from the display using the same DSI link in case of bidirectional display. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. [Figure 7-87](#) details the DSI protocol engine architecture.

Figure 7-87. DSI Protocol Engine

dss-166

NOTE: The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be Clock or Data. The DSI complex I/O receives the configuration for pin order and the differential +/- in a pair from the settings in DSS.DSI_COMPLEXIO_CFG1 register.

The DSI serial interface is a bidirectional differential serial interface with data/clock for the physical layer (configured in unidirectional link in case the display module is only unidirectional). The maximum DSI data transfer capacity is 900 Mbps per channel. The speed of the link can be software configured only when the DSI_PHY is in stop state or in ULPS.

Figure 7-88 shows the DSI transmitter/receiver high-level data flow.

7.4.3.2.1 Timing Parameters for an LP to HS Transaction

Figure 7-89 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 7-31 lists the LP to HS timing parameters.

Figure 7-89. LP to HS Timing

dss-325

Table 7-31. LP to HS Timing Parameters

Timing	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T _{LPX}	Length of any low-power state period	DSI_PHY_REGISTER1[20:16] REG_TLPXBY2 The value set in this bit field is half of the T _{LPX}	CEIL (25 ns / DDR_Clock_Period)	CEIL (2 * REG_TLPXBY2/4) * 4 * DDR_Clock_Period
T _{CLK-PREPARE}	Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission	DSI_PHY_REGISTER2[7:0] REG_TCLKPREPARE	CEIL (65 ns / DDR_Clock_Period)	REG_TCLKPREPARE * DDR_Clock_Period + (~- 25 ns - +5 ns)
T _{CLK-ZERO}	Time to drive the CLK lane to HS-0 state, before starting the clock	DSI_PHY_REGISTER1[7:0] REG_TCLKZERO	CEIL (265 ns / DDR_Clock_Period)	{CEIL [(REG_TCLKZERO + 3)/4] * 4 + CEIL (REG_TCLKPREPARE/4) * 4 - REG_TCLKPREPARE + 2} * DDR_Clock_Period + (~ 0 ns - +5 ns)

Table 7-31. LP to HS Timing Parameters (continued)

Timing	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
$T_{CLK-PRE}$	Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode	N/A	N/A	$DDR_CLK_PRE - T_{LPX} - T_{CLK-PREPARE} - T_{CLK-ZERO}$
$T_{HS-PREPARE}$	Time to drive the data lane to LP-00 state, to prepare for HS packet transmission	DSI_PHY_REGISTER0 [31:24] REG_THSPREPARE	CEIL (70 ns / DDR_Clock_Period) + 2	REG_THSPREPARE * DDR_Clock_Period + (-26.5 ns - +4 ns)
$T_{HS-ZERO} + T_{HS-PREPARE}$	$T_{HS-ZERO}$: Time to drive the data lane to HS-0 state before the synchronous sequence	DSI_PHY_REGISTER0 [23:16] REG_THSPRPR_THSZERO	CEIL (175 ns / DDR_Clock_Period) + 2	{CEIL [(N + 3)/4] * 4 + CEIL (M/4) * 4 + 3} * DDR_Clock_Period + (~ - 29 ns - 0 ns). Where N = REG_THSPREPARE_TH SZERO - REG_THSPREPARE M = REG_THSPREPARE
$T_{DDR_CLK_PRE}$	Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS	DSI_CLK_TIMING [15:8] DDR_CLK_PRE	CEIL [($T_{LPX} + T_{CLK-PREPARE}$ + $T_{CLK-ZERO} + T_{CLK-PRE}$) / $T_{TXBYTECLKHS}$] ⁽¹⁾⁽²⁾	
$T_{ENTER_HS_MODE_LATENCY}$	⁽³⁾ Time to enter data lane into HS mode	DSI_VM_TIMING7 [31:16] ENTER_HS_MODE_LATENCY	CEIL [($T_{LPX} + T_{HS-PREPARE} +$ $T_{HS-ZERO}$) / $T_{TXBYTECLKHS}$] ⁽¹⁾	

⁽¹⁾ The timings seen on the line should be used to determine the register value.

⁽²⁾ See the MIPI D-PHY specification for the $T_{CLK-PRE}$ value.

⁽³⁾ ENTER_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in [Table 7-32](#), the DDR clock = 400 MHz; TxByteClkHS = 100 MHz.

Table 7-32. LP to HS Timing Parameters Example for 400-MHz DDR Clock

Timing	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line
T_{LPX}	DSI_PHY_REGISTER1 [20:16] REG_TLPXBY2	10	50 ns
$T_{CLK-PREPARE}$	DSI_PHY_REGISTER2 [7:0] REG_TCLKPREPARE	26	40–70 ns
$T_{CLK-ZERO}$	DSI_PHY_REGISTER1 [7:0] REG_TCLKZERO	106	280–285 ns
$T_{CLK-PRE}$ ⁽¹⁾	N/A	N/A	80 ns
$T_{HS-PREPARE}$	DSI_PHY_REGISTER0 [31:24] REG_THSPREPARE	30	48.5–79 ns
$T_{HS-ZERO}$	DSI_PHY_REGISTER0 [23:16] REG_THSPRPR_THSZERO	72	178.5–207.5 ns
$T_{DDR_CLK_PRE}$	DSI_CLK_TIMING [15:8] DDR_CLK_PRE	45–49 ⁽²⁾	450–490 ns
$T_{ENTER_HS_MODE_LATENCY}$	DSI_VM_TIMING7 [31:16] ENTER_HS_MODE_LATENCY	24 * $T_{TXBYTECLKHS}$ or 96 * DDR_CLOCK 34 * $T_{TXBYTECLKHS}$ or 136 * DDR_CLOCK ⁽²⁾	277–336.5 ns

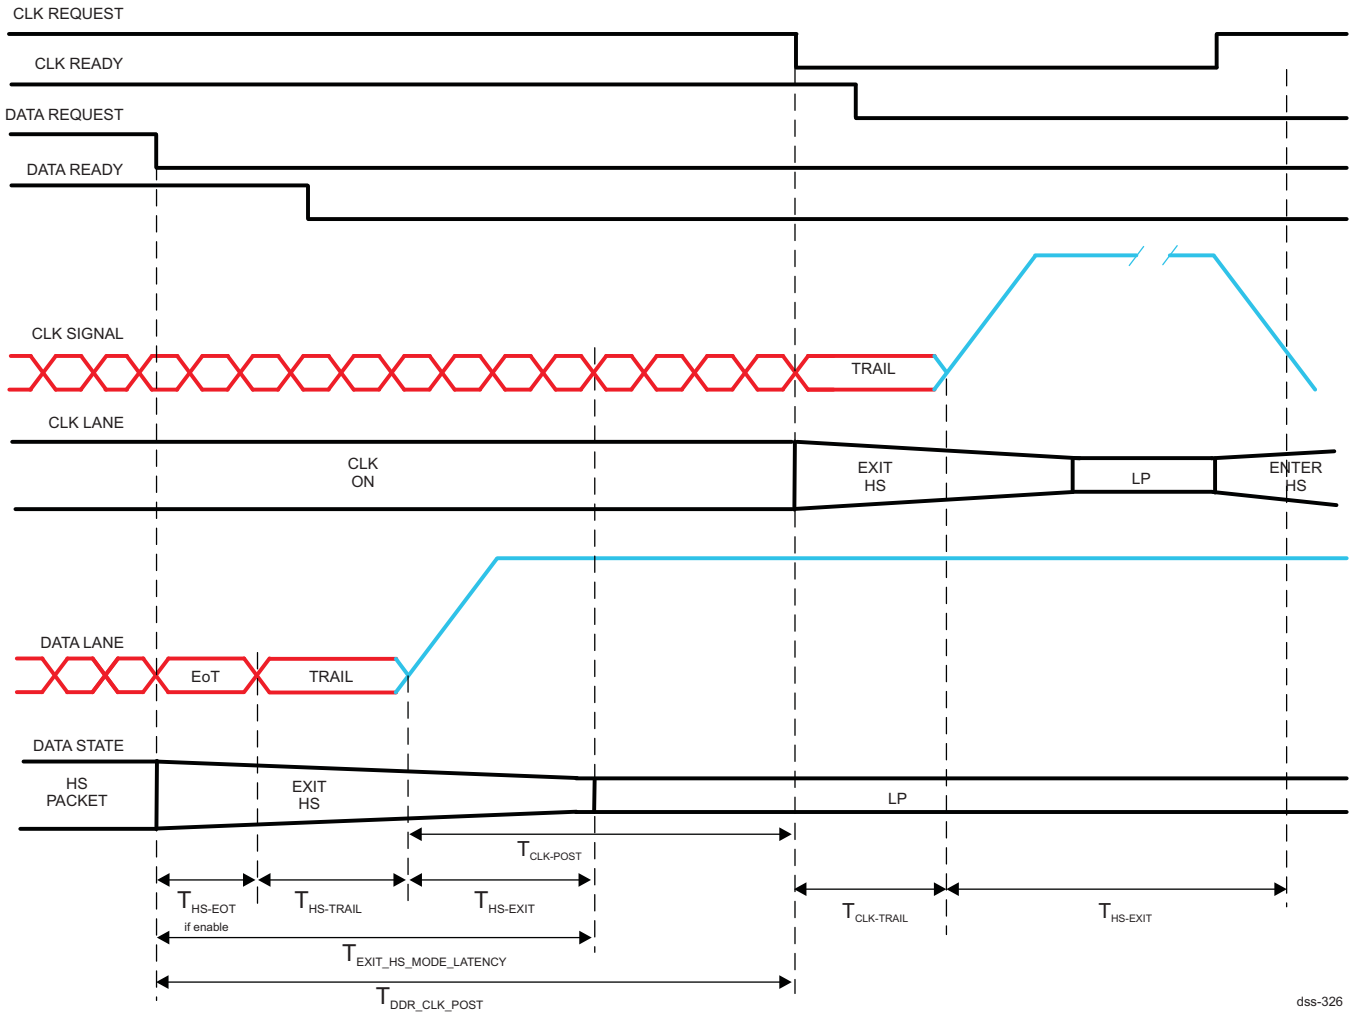

⁽¹⁾ See the MIPI D-PHY specification for the $T_{CLK-PRE}$ value.

⁽²⁾ The register setting is calculated based on the values in the Timing Seen on the Line column.

7.4.3.2.2 Timing Parameters for an HS to LP Transaction

Figure 7-90 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. Table 7-33 lists the HS to LP timing parameters.

Figure 7-90. HS to LP Timing

dss-326

Table 7-33. HS to LP Timing Parameters

Timing	Description	Registers/Associated Bit Fields	Register Settings	Timing Seen on the Line
T_{HS-EOT}	If EoT is enabled, a delay is added to EXIT_HS_MODE_LATENCY to send the EoT packet. The EoT period depends on the number of data lanes.	N/A	N/A	DIVROUNDUP (4, NB_DATA_LANES) Thus: One data lane = Four DDR clocks Two data lanes = Two DDR clocks
$T_{HS-TRAIL}$	Time to drive flipped differential state after last payload data bit of an HS transmission burst	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	CEIL (60 ns / DDR_Clock_Period) + 5	{CEIL [(REG_THSTRAIL + 3)/4] * 4 - 2.75} * DDR_Clock_Period + (~ 0 ns - 5 ns)
$T_{HS-EXIT}$	Time to drive data lane to LP-11 state, after HS burst	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	CEIL (145 ns / DDR_Clock_Period)	[CEIL (REG_THSEXIT/4) * 4] * DDR_Clock_Period - (~ 3 ns - 45 ns)
$T_{CLK-POST}$	Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode	N/A	N/A	DDR_CLK_POST - $T_{HS-EOT}^{(1)}$ - $T_{HS-TRAIL}$
$T_{CLK-TRAIL}$	Time to drive HS differential state after last payload clock bit of a HS transmission burst	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	CEIL (60 ns / DDR_Clock_Period) + 2	{CEIL [(REG_TCLKTRAIL + 3)/4] * 4 - 1.5} * DDR_Clock_Period + (~ 0 ns - 5 ns)
$T_{DDR_CLK_POST}$	Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: $T_{DDR_CLK_POST} \geq T_{HS-TRAIL} + T_{HS-EOT} + T_{CLK-POST}$	DSI_CLK_TIMING[7:0] DDR_CLK_POST	CEIL [($T_{HS-TRAIL} + T_{HS-EOT}^{(1)}$ + $T_{CLK-POST}$) / $T_{TXBYTECLKHS}^{(2)(3)}$]	
$T_{EXIT_HS_MODE_LATENCY}^{(4)}$	Time to exit HS mode	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY	CEIL [($T_{HS-TRAIL} + T_{HS-EXIT} + T_{HS-EOT}^{(1)}$) / $T_{TXBYTECLKHS}^{(2)}$]	

(1) If T_{HS-EOT} is enabled

(2) The timings seen on the line should be used to determine the register value.

(3) See the MIPI D-PHY specification for the $T_{CLK-POST}$ value.

(4) EXIT_HS_MODE_LATENCY timing applies only to video mode. It does not need to be programmed in command mode.

In the example in [Table 7-34](#), the DDR clock = 400 MHz; TxByteClkHS = 100 MHz; two data lanes.

Table 7-34. HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes

Timing	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line (T_{HS-EOT} Enabled)	Timing Seen on the Line (T_{HS-EOT} Disabled)
T_{HS-EOT}	N/A	N/A	5 ns	N/A

Table 7-34. HS to LP Timing Parameters Example for 400-MHz DDR Clock and Two Data Lanes (continued)

Timing	Registers/Associated Bit Fields	Default Register Settings (Programmed at Reset)	Timing Seen on the Line (T _{HS-EOT} Enabled)	Timing Seen on the Line (T _{HS-EOT} Disabled)
T _{HS-TRAIL}	DSI_PHY_REGISTER0[15:8] REG_THSTRAIL	29	73.125–78.125 ns	73.125–78.125 ns
T _{HS-EXIT}	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	58	105–147 ns	105–147 ns
T _{CLK-POST} ⁽¹⁾	N/A	N/A	585 ns	580 ns
T _{CLK-TRAIL}	DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL	26	76.25–81.25 ns	76.25–81.25 ns
DDR_CLK_POST	DSI_CLK_TIMING[7:0] DDR_CLK_POST	66 * TxByteClkHS or 264 * DDR_CLOCK – 67 * TxByteClkHS or 268 * DDR_CLOCK ⁽²⁾	658.125–663.125 ns	653.125–658.125 ns
EXIT_HS_MODE_LATENCY	DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY	19 * TxByteClkHS or 76 * DDR_CLOCK – 24 * TxByteClkHS or 96 * DDR_CLOCK ⁽²⁾	183.125–230.125 ns	178.125–225.125 ns

⁽¹⁾ See the MIPI D-PHY specification.

⁽²⁾ The register setting is calculated based on the values in the Timing Seen on the Line (T_{HS-EOT} Enabled) column.

7.4.3.2.3 Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last low speed transfer. The same value is used for all the VCs sending packets in low speed mode.

The size of the payload is defined by the DSS.DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE bit field. The header value depends on the VC ID and the size of the payload as detailed in [Table 7-35](#) and [Table 7-36](#).

Table 7-35. Extra NULL Packet Header

Virtual Channel ID	Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE)	Header (1st Byte)	Header (2nd Byte): WC LSB	Header (3rd Byte): WC MSB	Header (ECC)
0x0	0	0x9	0x0	0x0	0x9
	1		0x1		0x13
	2		0x2		0x2F
	3		0x3		0x35
0x1	0	0x49	0x0		0x1F
	1		0x1		0x05
	2		0x2		0x39
	3		0x3		0x23
0x2	0	0x89	0x0		0x10
	1		0x1		0x0A
	2		0x2		0x36
	3		0x3		0x2C
0x3	0	0xC9	0x0	0x06	
	1		0x1	0x1C	
	2		0x2	0x20	
	3		0x3	0x3A	

Table 7-36. Extra NULL Packet Payload

Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_ SIZE)	Payload (1st byte)	Payload (2nd byte)	Payload (3rd byte)	Payload (CRC) LSB	Payload (CRC) MSB
0	NA	NA	NA	0xFF	0xFF
1	0	NA	NA	0x87	0x0F
2	0	0	NA	0xB8	0xF0
3	0	0	0	0x33	0x39

NOTE:

- In [Table 7-35](#) and [Table 7-36](#), both ECC and checksum are enabled.
- NA means not available.

7.4.3.3 DSI Transfer Modes

There are two transfer modes supported by the DSI module:

- Video mode (VM): Pixels are received from the video port, there are some real time constraints (pixels must be sent at the pixel frequency required by the display module) for sending the data to the display;
- Command mode (CM): Pixels can be received from the video port or from the L4 interconnect, there are no real time constraints except that TE must be avoided by starting the transfer at the right time during scan of the display and should be fast enough.

7.4.3.3.1 Video Mode

The video mode refers to the MIPI DPI 1.0 standard. The sync events and pixels must be sent according to the display mode timings. Data are received from the video port. The display controller is in charge of fetching the data from the system memory and providing the data to the DSI protocol engine using the video port. The short packets used for the sync event are using precalculated 32-bit values. The long packets are constructed using the header defined in DSS.DSI_VCn_LONG_PACKET_HEADER registers.

7.4.3.3.2 Command Mode

The command mode refers to the MIPI DCS standard. The commands, parameters and pixels are sent to the display module with limited real time constraints (as defined in [Section 7.4.3.3.1](#)). The pixels can be provided on the video port by the display controller or on the L4 interconnect port.

NOTE: In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

The DSS.DSI_VCn_LONG_PACKET_HEADER registers are used for the header of long packets, the DSS.DSI_VCn_SHORT_PACKET_HEADER registers are used for the short packets.

The error correction code (ECC) can be provided while writing the ECC value directly into the DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_SHORT_PACKET_HEADER registers. The DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit indicates if the ECC value should be calculated or if the value written in the register should be used instead for command and video modes. In case of synchronization short packets for video mode, since the hardware generates the short packets without using DSS.DSI_VCn_SHORT_PACKET_HEADER registers. If the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit is set to 1, the ECC is calculated; otherwise, the value zero is used. The feature is used to generate incorrect ECC for debug purpose and to ease the check for the link and peripheral error detection and correction.

For the payload, the DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used. Each 32-bit PAYLOAD data is written into the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register from the MPU subsystem or system DMA. It is buffered to be able to send packets with higher rate than the L4 interconnect frequency can provide. The word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER registers is used to determine the number of bytes to be sent using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers. The write into the DSS.DSI_VCn_LONG_PACKET_HEADER registers is required before accessing the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware must be able to extract the length of the payload and be able to discard extra data sent using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware takes into account the write into the DSS.DSI_VCn_LONG_PACKET_HEADER register only if the VC is enabled otherwise the write is ignored by hardware.

In the case of pixels received on the video port, only the DSS.DSI_VCn_LONG_PACKET_HEADER register is used. The video port pixels are used for the payload. When the pixel data is coming from the display controller video port, the DSI protocol can add a DCS command byte between the packet header and pixel data by setting the DSS.DSI_CTRL[24] DCS_CMD_ENABLE bit to 0x1. The value will be either 0x2c (write_memory_start) by setting the DSS.DSI_CTRL[25] DCS_CMD_CODE bit to 0x1, or 0x3c (write_memory_continue) by setting the DSS.DSI_CTRL[25] DCS_CMD_CODE bit to 0x0.

When transmitting RGB 16-BPP data, the DSS.DSI_CTRL[26] RGB565_ORDER bit must be set to 0x1 to maintain the pixel byte order as in video mode .

A 2-line ping-pong buffer is implemented to allow the DSI protocol engine to store incoming pixels from the display controller through the video port while sending the DSI formatted frame to the DSI_PHY. The ping-pong buffer is supported in command mode, provided the size of the packet defined in the header register is less than the size of each line buffer (768 *32 bits). If the size of the packet is greater than the size of the line buffer, the ping-pong mechanism cannot be used (both lines are used as a single line).

The ping-pong buffer status can be checked by the DSI_VCn_CTRL[14] PP_BUSY bit.

- When PP_BUSY equals 1, the ping-pong buffer is active and the line buffers are not ready to receive data; therefore, the user cannot update a new header.
- When PP_BUSY equals 0, at least one line buffer is empty; therefore, the user can update a new header. PP-BUSY is then set to 0x1. If both line buffers are empty, the user can write two headers, one following the other. PP_BUSY remains at 0x0 after the first header is written, and is set to 0x1 after second header is written.

An IRQ is available to allow software to update header on events. The IRQ is enabled by setting the DSI_VCn_IRQENABLE[8] PP_BUSY_CHANGE_IRQ bit to 0x1, and its status is accessible on the DSI_VCn_IRQSTATUS[8] PP_BUSY_CHANGE_IRQ bit.

7.4.3.3.3 Video + Command Modes

The two modes can be interlaced to send two DSI streams to two types of panels: Video or command types. The number of concurrent video stream is limited to a single one. The number of concurrent command mode streams is limited to 4 when there is no video stream and 3 otherwise. In case there is one DSI stream using video mode, the command mode pixels must be provided only on the L4 interconnect.

7.4.3.3.4 Burst Modes

- Frequency-burst mode The frequency-burst mode is used to reduce the high-speed (HS) period by increasing the clock frequency on the DSI link. It allows in some case, the power consumption reduction of the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine needs to buffer a full line before sending the HS packets for the line. A double buffering mechanism is required to be able to send a line while the following one is being received on the video port.
- Transparent-burst mode The transparent-burst mode is used by increasing the pixel clock frequency generated by the display controller with in addition an increase of the horizontal blanking period.

7.4.3.3.5 Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L4 interconnect, during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as high-speed packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line

To perform interleaving in a particular gap, video mode must be set to go into low-power state during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into low-power state during the gap on the PPI link. If low-power state is set during a gap, the DSI module performs interleaving during that period.

Two set of registers are available for:

- High-speed interleaving (when high-speed command mode packets must be sent during a video stream on the PPI link)
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link)

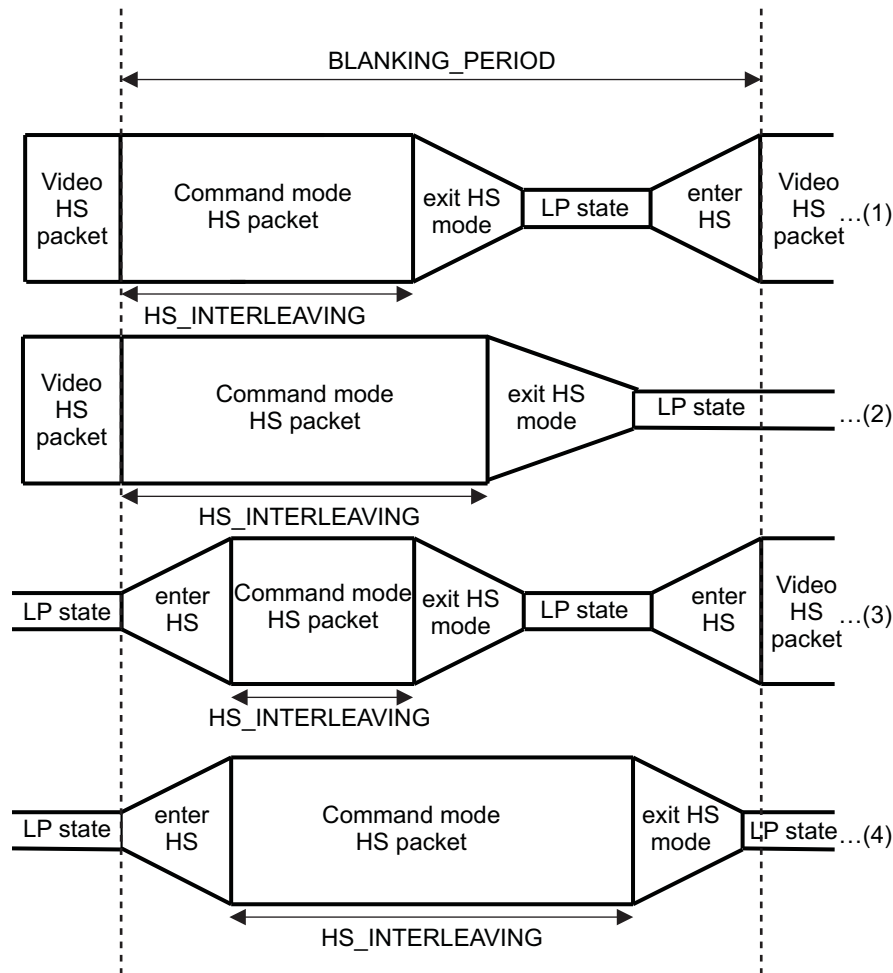

7.4.3.3.5.1 HS Command Mode Interleaving Programming Model

Figure 7-91 shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in HS command mode packets.

- The BL_HS_INTERLEAVING[31:16] [DSI_VM_TIMING6](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The HBP_HS_INTERLEAVING[7:0] [DSI_VM_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The HFP_HS_INTERLEAVING[15:8] [DSI_VM_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The HSA_HS_INTERLEAVING[23:16] [DSI_VM_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

Figure 7-91. HS Command Mode Interleaving

dss-327

NOTE: For calculations and equations, the following abbreviations are used: EXIT_CLK_HS_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations.

$$\text{EXIT_CLK_HS_MODE} = T_{\text{CLK-TRAIL}} + T_{\text{HS-EXIT}}$$

For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the BL_HS_INTERLEAVING, HSA_HS_INTERLEAVING, HBP_HS_INTERLEAVING, or HFP_HS_INTERLEAVING registers, depending on the blanking type.

In each scenario, two calculations are present, depending on the value of ddr_clk_always_on.

- ddr_clk_always_on = 1: Clock lane is always active.
- ddr_clk_always_on = 0: Clock lane is activated only when there are HS packets to be sent on the PPI link.
- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
 - ddr_clk_always_on = 1

$$\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$
 - ddr_clk_always_on = 0

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + \max\{$$

$$\text{ENTER_HS_MODE_LATENCY, 2} + 1)$$

$$\text{HS_INTER2} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + \text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + 1)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.
 - $\text{ddr_clk_always_on} = 1$

$$\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + 3)$$
 - $\text{ddr_clk_always_on} = 0$

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + 3)$$

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + 3)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
 - $\text{ddr_clk_always_on} = 1$

$$\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$
 - $\text{ddr_clk_always_on} = 0$

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$

$$\text{HS_INTER2} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + \text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + 1)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$
- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
 - $\text{ddr_clk_always_on} = 1$

$$\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + 3)$$
 - $\text{ddr_clk_always_on} = 0$

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + 3)$$

$$\text{HS_INTER2} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + 1)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$

7.4.3.3.5.2 LP Command Mode Interleaving Programming Model

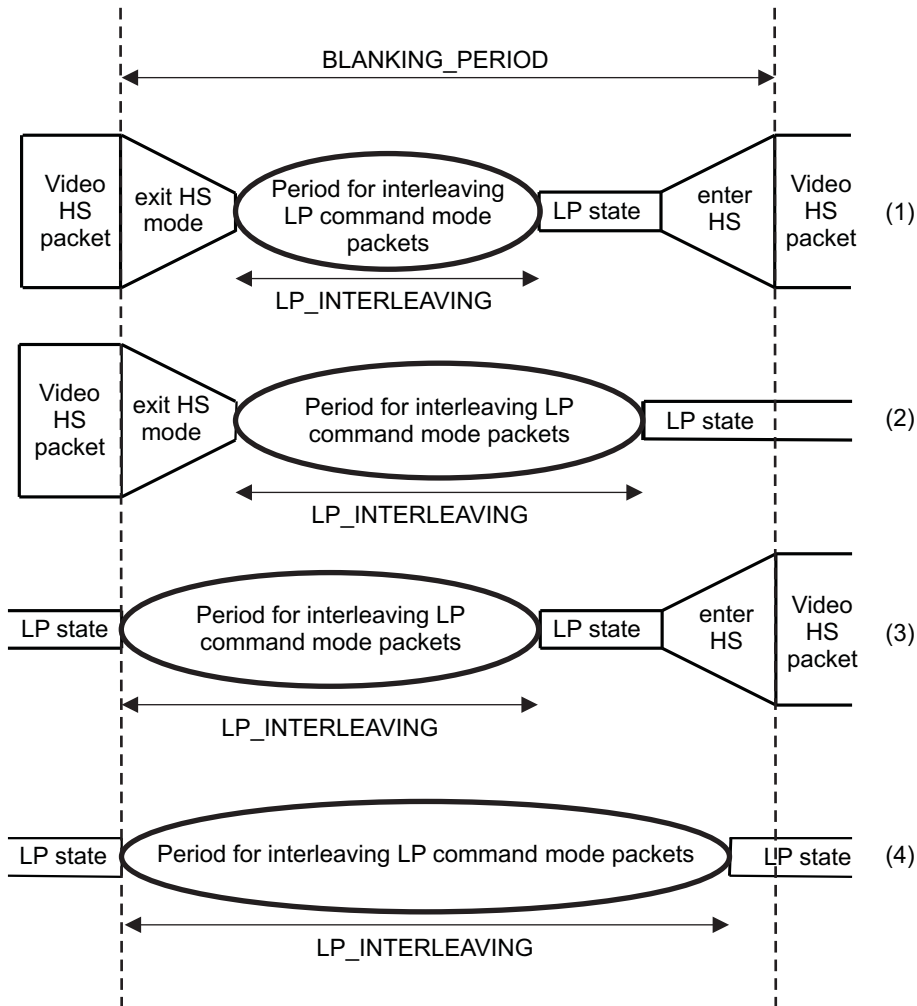

Figure 7-92 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of bytes of LP command mode packets that can be sent during a blanking period.

- BL_LP_INTERLEAVING bit field [DSI_VM_TIMING6\[15:0\]](#) defines the number of bytes of LP command mode packets that can be sent during a BLLP gap.
- HBP_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[7:0\]](#) defines the number of bytes of LP command mode packets that can be sent during a HBP gap.
- HFP_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[15:8\]](#) defines the number of bytes of LP command mode packets that can be sent during a HFP gap.
- HSA_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[23:16\]](#) defines the number of bytes of LP command mode packets that can be sent during a HSA gap.

These programmable values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane high-speed and low-power mutually exclusive control. Clock lanes can be in high-speed mode while the data lanes are in high-speed data transfer mode, low-power data transfer mode, or in low-power state.

According to this scenario, different equations must be considered for calculating register values.

Figure 7-92. LP Command Mode Interleaving

dss-328

For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The LP_INTERLEAVING period represents the maximal period in LP command mode packets. Its value is set in the BL_LP_INTERLEAVING, HSA_LP_INTERLEAVING, HBP_LP_INTERLEAVING, or HFP_LP_INTERLEAVING registers, depending on the blanking type.

ALLOWED_HSBYTE_CLOCKS_FOR_LP represents the number of TxByteClkHS clock cycles during which LP interleaving can appear.

To calculate the LP_INTERLEAVING value:

1. Calculate how many TxByteClkHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the LP_INTERLEAVING value according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + 1)$$

- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$

- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - 1$$

After finishing Step 1, the time period available for LP interleaving is known:

$$T_{lp_available} = \text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} * T_{TxByteClkHS}$$

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$\text{LP_INTERLEAVING} < \left[\frac{T_{lp_available} - 8 * T_{hsbyte_clk} - 5 * T_{dsif_clk} - 26}{\frac{T_{txclkesc}}{16}} \right]$$

dss-E124

TxByteClkHS: Period of HS byte clock of DSI_PHY module

Tdsif_clk: Period of DSI functional clock

Ttxclkesc: Period of LP transmit escape clock

7.4.3.4 Power Management

The DSI protocol engine implements an handshake protocol on its L4 interconnect port with the PRCM. The DSI protocol engine provides a clock gating signal CIO_CLK_ICG to gate the L3 interface clock (L3_ICLK) provided by the PRCM to the DSI complex I/O. It allows reduction of the power consumption of the DSI complex I/O while the DSI link is not in used. To gate the L3_ICLK clock at DSI complex I/O level, set the DSS.DSI_CLK_CTRL[14] CIO_CLK_ICG bit to 1.

7.4.3.5 Serial Configuration Port (SCP) Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL Control module and to the DSI complex I/O. It spends several cycles to serialize the data to be sent. Software users must consider the delay in processing the transfer of the data from/to the slave port to/from the module.

7.4.3.5.1 Shadowing Register

The two first SCP registers for the DSI complex I/O address map must be implemented as shadow registers. The shadowing mechanism is enabled/disabled using the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit:

- When setting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 1, the transfer of the values from the two first L4 interconnect port registers into the two first registers of the DSI complex I/O (DSS.DSI_PHY_REGISTER0 and DSS.DSI_PHY_REGISTER1) is done only when the DISPC_UPDATE_SYNC signal from the display controller is active and the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is set to 1. If there is no pending update for the two registers, when the DISPC_UPDATE_SYNC signal is asserted, the DSS.DSI_COMPLEXIO_CFG1[30] GObit is reset by hardware and there is no SCP transfer.
 - If there is only one register to update, only the corresponding new value is transferred. The second register in the DSI complex I/O is not updated. When the transfer is completed, the

DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.

- If the two registers need to be updated, the order of the transfer is first the register with lower address and then the second one. When the transfers are completed, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.

When there is an on-going transfer (read or write) to any SCP register, the transfer must complete before starting the update of shadowing registers.

- When unsetting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 0, if the transfer into the two first DSI complex I/O registers has already started, it should be finished.

NOTE: When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending; otherwise, the values stored in the DSI complex I/O are returned.

7.4.3.5.2 Busy Signal

The signal SCPBusy indicates that there is still some activity using the SCPClk provided by the PRCM. The SCPClk clock is the DSS_L3_ICLK clock.

7.4.3.6 Power Control

The DSI protocol engine can control and send power commands for both DSI complex I/O and DSI PLL controller modules.

7.4.3.6.1 Complex I/O Power Control Commands

7.4.3.6.1.1 Complex I/O Power Control Commands

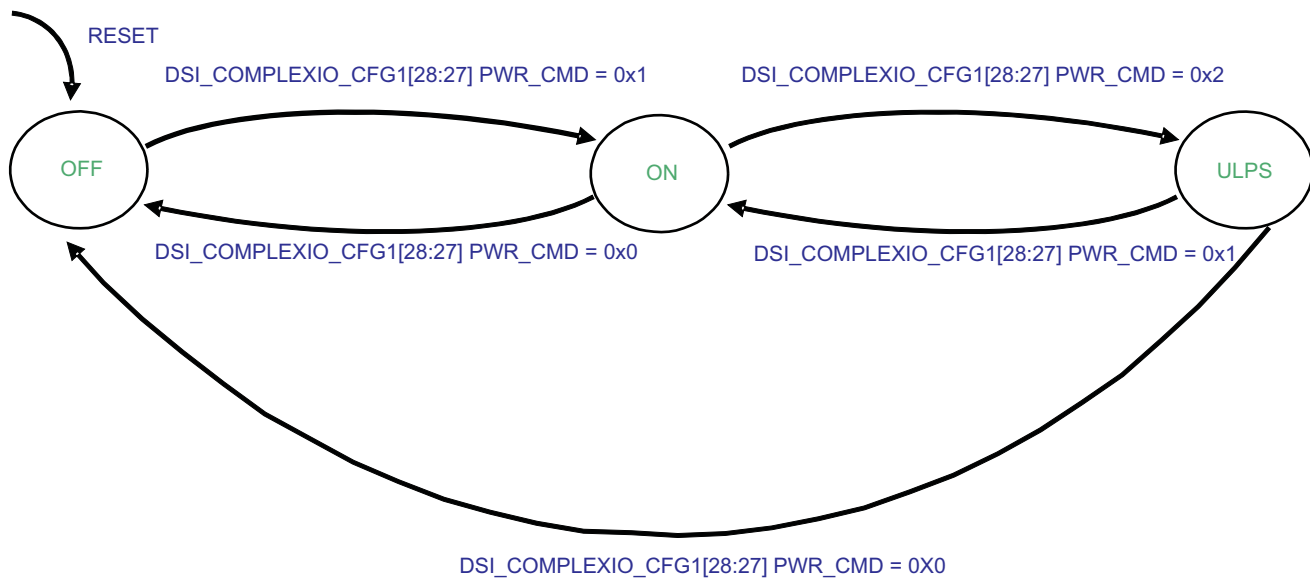

The DSI complex I/O can be set into three modes:

- OFF: In this power state, the complete DSI_PHY circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete DSI_PHY circuit is powered on and functional.
- ULPS: In this power state, the ULPS exit detection circuit power switch is ON for the lanes which are in receive ULPS mode. For the lanes which are in transmit ULPS mode, the circuitry for weak pull-down is ON. The ultralow-power state should only be used when all the three lanes are in ULPS (transmit or receive).

7.4.3.6.1.2 Complex I/O Power FSM

Figure 7-93 describes the power control FSM to control the power state of the complex I/O.

Figure 7-93. Complex I/O Power FSM

dss-169

The PwrCmdOff, PwrCmdUlp and PwrCmdOn commands control the state transition of the DSI complex I/O. Software users must set the DSS.DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field to ask for a state change. The allowed transitions are: OFF - ON and ON - ULP and ULP - OFF. The DSS.DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS bit field gives a status on the current state of the DSI complex I/O.

CAUTION

- In automatic mode, software must ensure that the DSI complex I/O in the ON mode (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI complex I/O).
- To change state to ULP state, users must ensure that all the three ULPSActiveNot signals are low. The ULPSActiveNot_ALL0_IRQ interrupt can be used by software users to determine the state of the ULPSActiveNot signals. The change from ULP to ON state is required before starting the ULP status exit sequence (see Section 7.4.3.7.1 for details).

7.4.3.6.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set into four modes:

- OFF: The DSI PLL and HSDIVIDER are OFF.
- ON ALL: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is provided to the DSI complex I/O and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The HS_CLK clock is provided to the DSI complex I/O but the second clock output is not provided to the HSDIVIDER.
- ON DIV: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is not provided to the DSI complex I/O but the second clock output is provided to the HSDIVIDER.

7.4.3.6.2.1 DSI-PLL Power FSM

Figure 7-94 shows the DSI PLL power FSM.

Figure 7-94. DSI PLL Power FSM

- 1 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x0 (STATE_OFF)
- 2 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x1 (STATE_ON_HSCLK)
- 3 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x2 (STATE_ON_ALL)
- 4 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x3 (STATE_ON_DIV)

dss-170

The commands PLLPwrCmdOff, PLLPwrCmdOnAll, PLLPwrCmdOnDIV and PLLPwrCmdOnHSCLK controls the state transition of the DSI PLL control module. Software users must set the DSS.DSI_CLK_CTRL[31:30] PLL_PWR_CMD bit field to ask for a state change. The DSS.DSI_CLK_CTRL[29:28] PLL_PWR_STATUS bit field gives a status on the current state of the DSI PLL controller.

NOTE: In a command requests to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL Control module).

All the DSI PLL power is controlled by the DSI protocol engine except the LDO power of the PLL and HSDIVIDER that can be controlled by the DSI PLL controller module. Indeed, the HSDIVIDER and PLL SYSRESET signals can be forced by the DSI PLL controller module by setting DSS.DSI_PLL_CONTROL[4] DSI_HSDIV_SYSRESET and DSS.DSI_PLL_CONTROL[3] DSI_PLL_SYSRESET bits, respectively. By setting these bits to 1, the SYSRESET signal is forced active (module is forced to reset state). When these bits are set to 0 (reset value), the SYSRESET signals are controlled by the DSI PLL power FSM.

7.4.3.6.2.1.1 DSI-PLL HS Clock Signals

The DSIStopClk signal is provided to the DSI PLL control module. It indicates when the DSI Protocol engine does not need to use the high-speed transfer mode (HS mode) and PLL HS output (HS_CLK clock) can be stopped. The following conditions must also be met when DISPC_UPDATE_SYNC may be generated by the display controller, as that may also result in the PLL HS output being stopped.

When the interface is disabled (that is, DSS.DSI_CTRL[0] IF_EN bit set to 0), the signal DSISStopClk is asserted.

The assertion of the DSISStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is not required anymore). The get TxRequestHS deassertion, all of the following conditions are required:
 - The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be reset to 0 and no HS data transfer should be ongoing or already scheduled.
 - No VC active in video mode. No VC using the video mode is enabled; if the VC is enabled, the mode is command mode only (that is, DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1 and DSS.DSI_VCn_CTRL[4] MODE bit set to 0).
 - No command mode requiring high-speed transfer (one or more VCs using command mode can be active)
 - Or DSS.DSI_CTRL[0] IF_EN bit reset to 0 (if all previous conditions are not required)

The deassertion of the DSISStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit to 1):

- Clock lane TxRequestHS must be asserted (the DDR clock on the clock lane is required anymore).
- One video mode VC active
- At least one VC in command mode requiring high-speed transfer
- The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is set to 1 by software users (the DSS.DSI_CTRL[0] IF_EN bit must be reset to 0 to update the DDR_CLK_ALWAYS_ON bit value)

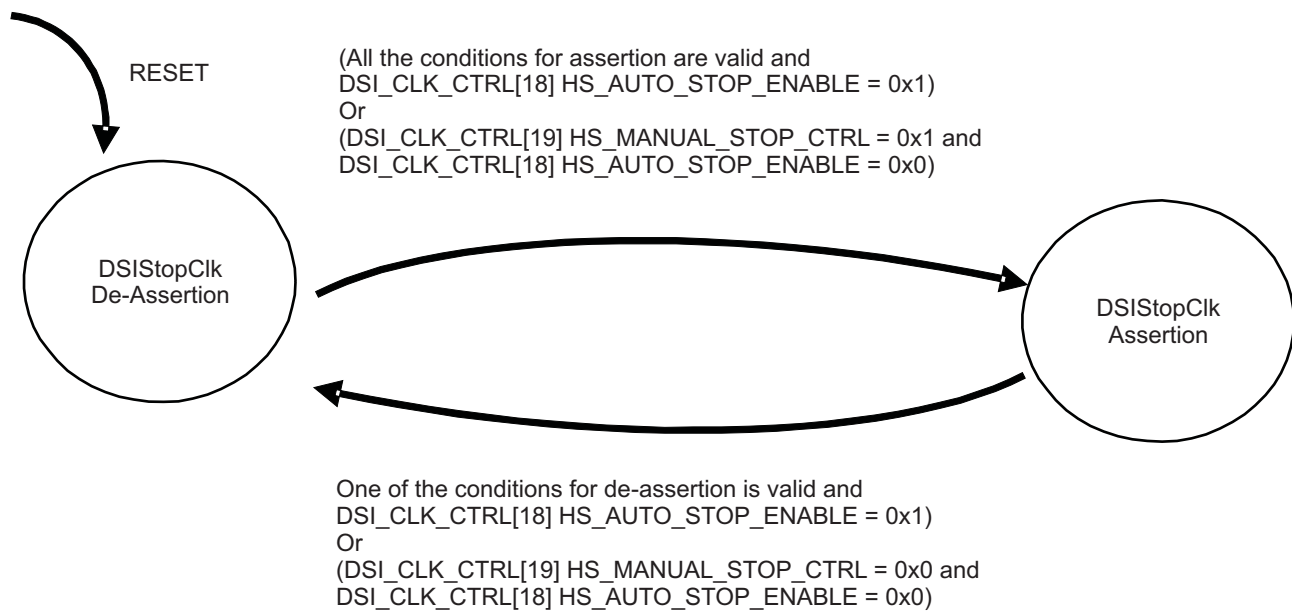

Automatic assertion/deassertion is enabled by using the DSS.DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE bit.

Manual mode can be used by setting/resetting the DSS.DSI_CLK_CTRL[19] HS_MANUAL_STOP_CTRL bit to assert/deassert the DSISStopClk signal.

7.4.3.6.2.1.2 DSI-PLL HS Clock FSM

Figure 7-95 shows the DSI PLL HS clock FSM.

Figure 7-95. DSI PLL HS Clock FSM

dss-171

When DSIStopClk is used there is a latency through other modules (DSI PLL controller and DSI_PHY) before TxByteClkHS is stopped. This latency must be accounted for to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSS.DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field. This timer is programmed in number of periods of the DSI Protocol functional clock (DSI_FCLK). At reset value, the timer is programmed with 0x80 (128) value.

CAUTION

The programmed value in the DSS.DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field must be greater than $((3 \times L3_ICLK \text{ period}) + (5 \times CLKIN4DDR \text{ period})) / (DSI_FCLK \text{ period})$.

7.4.3.7 Timers

NOTE: Among the timers described in this section, only the HS TX, LP RX and turnRequests timers generates interrupts immediately when the timer value is null. For ForceTxStopMode timer, it ends counting instantly and ForceTxStopMode is not asserted.

7.4.3.7.1 Twakeup Timer

The T_{WakeUp} timer is not implemented in the DSI protocol engine. The software must use a general-purpose (GP) timer to handle this. This timer is used for existing ULP status mode for the active lanes (clock and/or data lanes). The sequence to exit ULP state is:

1. Change the state of TxULPSExit for each lane to ACTIVE.
2. Wait for the interrupt indicating that all lanes with TxULPSExit active have acknowledged by asserting ULPSActiveNot. This is done by reading the DSS.DSI_COMPLEXIO_IRQSTATUS ULPSACTIVENOT_ALLi_IRQ bit fields ($i = 0, 1$).
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the TxUlpsClk signals to INACTIVE state for the clock lane and/or TxRequestEsc INACTIVE state for the data lane(s).

NOTE: The minimum time for the wake-up period is 1 ms.

To enter ULPS mode for clock lane, TxUlpsClk state must be changed to active state. To enter ULPS mode for data lane, TxRequestEsc state must be changed to active state (TxUlpsEsc as well if it is not already in active state).

7.4.3.7.2 ForceTxStopMode FSM

The signal ForceTxStopMode is used at initialization time (DSI complex I/O). [Figure 7-96](#) describes the ForceTxStopMode FSM to assert/deassert ForceTxStopMode signal.

Figure 7-96. ForceTxStopMode FSM

dss-172

The DSI protocol engine asserts ForceTxStopMode by setting the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit to 1. Asserting the FORCE_TX_STOP_MODE_IO bit allows to initialize the lanes. The lanes are in the Stop State when ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP_STATE_COUNTER_IO, Stop_State_x4_IO, Stop_State_x16_IO field DSI_TIMING1[15:0]. The FORCE_TX_STOP_MODE_IO bit is reset by hardware when the time is reached.

This bit can be reset by software.

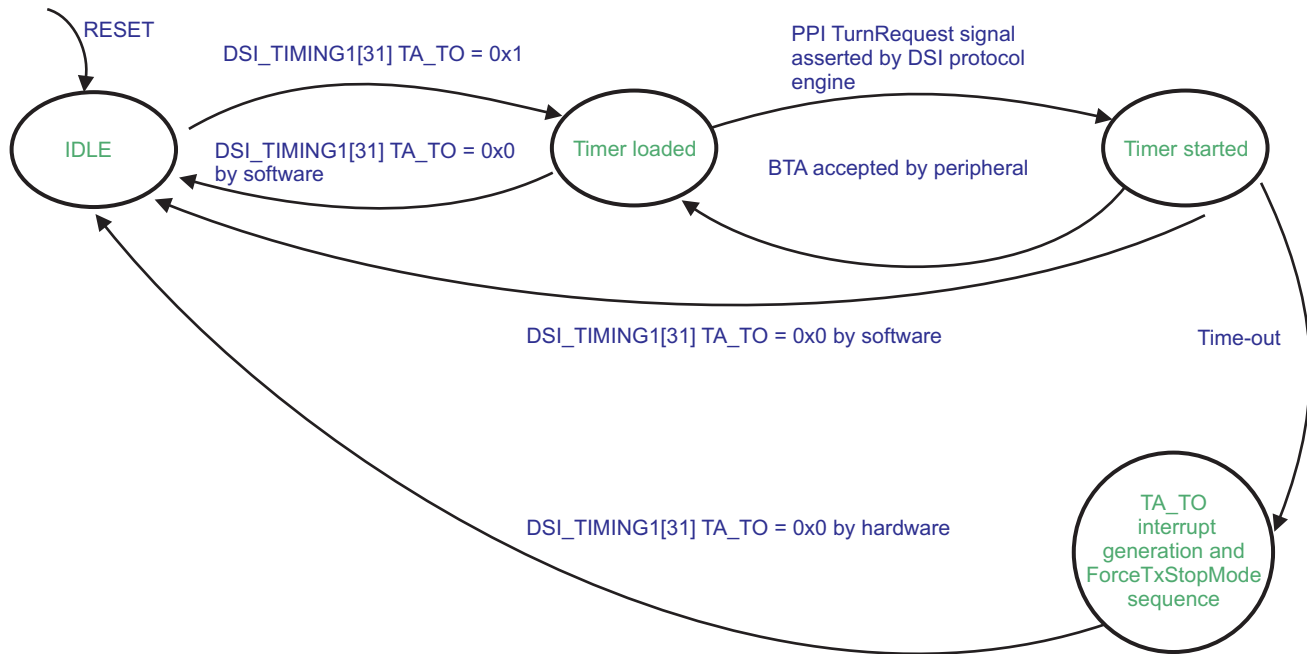

The calculation of the number of DSI_FCLK cycles assertion period is defined by:

$$\text{Total period in DSI_FCLK cycles} = \text{DSI_TIMING1}[12:0] \text{ STOP_STATE_COUNTER_IO} \times ((\text{DSI_TIMING1}[14] \text{ STOP_STATE_X16_IO} \times 15) + 1) \times ((\text{DSI_TIMING1}[13] \text{ STOP_STATE_X4_IO} \times 3) + 1)$$

7.4.3.7.3 TurnRequest FSM

The signal TurnRequest is used to request turnaround. It is only valid for the data lane #1 since the other data lanes cannot be used in the reverse direction to receive data from the DSI receiver. [Figure 7-97](#) describes the TurnRequest FSM to assert/deassert TurnRequest signal.

Figure 7-97. TurnRequest FSM

dss-173

The DSI protocol engine asserts TurnRequest signal during one TxClkEsc cycle when the turn-around is enabled through the DSS.DSI_VCn_CTRL[6] BTA_EN bit (for more information, see Section 7.4.3.8, Bus Turnaround). The DSS.DSI_TIMING1[31] TA_TO bit is set/reset by software to respectively enable/disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time out occurs.

The timer is loaded with the value in number of DSI_FCLK cycles:

$$\text{DSI_TIMING1}[28:16] \text{ TA_TO_COUNTER} \times ((\text{DSI_TIMING1}[30] \text{ TA_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING1}[29] \text{ TA_TO_X8} \times 7) + 1).$$

When the TA_TO_IRQ interrupt is generated (turn-around timer expired, and procedure failed), the hardware automatically asserts ForceTXStopMode in order for the DSI_PHY to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset to 0 before starting the recovery sequence.

7.4.3.7.4 Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Such as the Twakeup timer, a general-purpose timer (GPTimer) should be used in case of reset of the peripheral to determine when the peripheral is ready again for operation.

7.4.3.7.5 HS TX Timer

The HS TX timer is used to detect when the host has been in TX mode for too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of high speed transmission occurs. It is enabled/disabled by software through the DSS.DSI_TIMING2[31] HS_TX_TO bit. The interrupt HS_TX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[14] HS_TX_TO_IRQ bit is set to 1 when the HS TX time-out occurs.

The maximum time to be supported is 20 ms. It can be used to determine that at least once a frame in video mode, the HS mode is stopped to enter ULPS. Since the refresh rate can be up to 50 frames per second in video mode, the maximum time in HS is 20 ms.

The timer is loaded with the value in number of TxByteClkHS:

$$\text{DSI_TIMING2}[28:16] \text{ HS_TX_TO_COUNTER} \times ((\text{DSI_TIMING2}[30] \text{ HS_TX_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING2}[29] \text{ HS_TX_TO_X8} \times 7) + 1)$$

Figure 7-98. High-Speed TX Timer FSM

dss-174

When the time-out occurs, the hardware should send EOT request in order for the DSI complex I/O to drive LP-11 stop state. This is followed by the generation of the interrupt. The hardware will perform an internal logic reset including the TX FIFO content, but excluding the register values and then resets the DSS.DSI_CTRL[0] IF_EN bit.

The software should wait for the DSS.DSI_CTRL[0] IF_EN bit to be reset to 0 before taking any recovery action by resetting for example the peripheral if it is not responding.

7.4.3.7.6 LP RX Timer

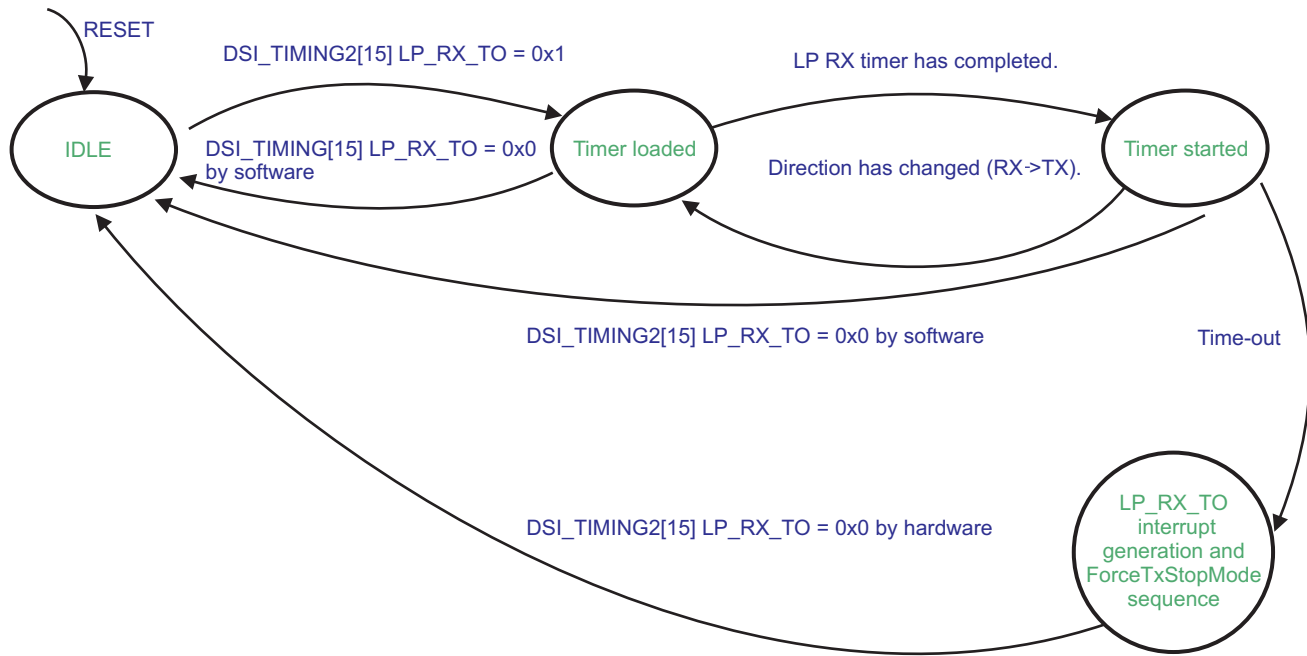

When the host is in Low power Receive mode after a bus turn-around, the LP RX timer is loaded. When the timer expires, the host requests the DSI complex I/O to drive LP-11. The interrupt LP_RX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[15] LP_RX_TO_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSS.DSI_TIMING2[15] LP_RX_TO bit is set/reset by the software to respectively enable/disable the timer.

The timer is loaded with the value in number of DSI_FCLK cycles:

$$\text{DSI_TIMING2}[12:0] \text{ LP_RX_TO_COUNTER} \times ((\text{DSI_TIMING2}[14] \text{ LP_RX_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING2}[13] \text{ LP_RX_TO_X4} \times 3) + 1)$$

Figure 7-99. Low-Power RX Timer FSM

dss-175

When the interrupt is generated, the hardware should automatically reset the DSS.DSI_TIMING2[15] LP_RX_TO bit and then assert ForceTXStopMode in order for the DSI complex I/O to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when DSS.DSI_VCn_CTRL[0] VC_EN is set to 1).

7.4.3.8 Bus Turnaround

The bus turn-around (BTA) is not automatically sent by default after each packet sent to the display(s). It is programmable independently for each VC ID. The VC can be enabled when DSS.DSI_VCn_CTRL[6] BTA_EN bit is set to 1 by software. The software should ensure that, when the BTA is sent to the peripheral, there is enough time allocated for the response and the BTA from the peripheral to host. For more information about possible DSI PHY timing adjustments during the turn-around procedure, see Section 7.5.6.4.3, Turn-Around Request in Transmit Mode, and Section 7.5.6.4.4, Turn-Around Request in Receive Mode. When setting the DSS.DSI_VCn_CTRL[6] BTA_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

Acknowledgment from the peripheral for successful BTA is indicated by asserting the BTA_IRQ interrupt, if it is enabled in the DSS.DSI_VCn_IRQENABLE[5] BTA_IRQ_EN bit. To monitor the BTA interrupt, the user should read the DSS.DSI_VCn_IRQSTATUS[5] BTA_IRQ status bit.

CAUTION

The BTA should not be sent when the RX FIFO is not empty. Users should take care of emptying the RX FIFO before sending BTA to the peripheral. It is to ensure that when receiving new data from peripheral, all the allocated spaces for all the VCs are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packets when respectively the `DSS.DSI_VCn_CTRL[2]` `BTA_SHORT_EN` or the `DSS.DSI_VCn_CTRL[3]` `BTA_LONG_EN` bits are set to 1.

NOTE: If the `DSS.DSI_VCn_CTRL[2]` `BTA_SHORT_EN` bit is enabled, users can still set the `DSS.DSI_VCn_CTRL[6]` `BTA_EN` bit. Only one BTA is sent to the peripheral and the `DSS.DSI_VCn_CTRL[6]` `BTA_EN` bit is reset by hardware.

If the `DSS.DSI_VCn_CTRL[3]` `BTA_LONG_EN` bit is enabled, users can still set the `DSS.DSI_VCn_CTRL[6]` `BTA_EN` bit. Only one BTA is sent to the peripheral and the `DSS.DSI_VCn_CTRL[6]` `BTA_EN` bit is reset by hardware.

If the `DSS.DSI_VCn_CTRL[2]` `BTA_SHORT_EN` and `DSS.DSI_VCn_CTRL[3]` `BTA_LONG_EN` bits are both enabled, users can still set the `DSS.DSI_VCn_CTRL[6]` `BTA_EN` bit to send a BTA. Only one BTA is sent and the `DSS.DSI_VCn_CTRL[6]` `BTA_EN` bit is reset by hardware.

As explained previously, two modes can be used for each VC ID:

- **Automatic:** After each packet, a bus turn-around is sent. To determine the size of the long packet, the protocol engine on the host side should read the word count defined in the header (in `DSS.DSI_VCn_LONG_PACKET_HEADER` register) and use it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. Then the bus turn-around is sent to the peripheral. The word count is also used to determine how many bytes should be transferred from the 32-bit writes access to the payload register (`DSS.DSI_VCn_LONG_PACKET_PAYLOAD` register).
- **Manual:** In case of data transfer using the L4 interconnect port, while all data have been provided to the DSI protocol engine, users can select bus turn-around for the last packet provided to the L4 interconnect port only by setting the bus turn-around enable bit (`DSS.DSI_VCn_CTRL[6]` `BTA_EN`) or for last packets and following ones by setting the automatic mode; in case of data transfer using the video port, the bus turnaround enable bit (`DSS.DSI_VCn_CTRL[6]` `BTA_EN`) can be selected at any time during the transfer of the packet. In case of video mode packets (data and synchronization events) users cannot determine when the BTA is sent relatively the video mode packets, so it is highly recommended to use manual BTA mode only for packets generated in command mode but it is possible to use BTA when for a VC in video mode. In case of data provided on the video port, an interrupt for end of packet transfer (`PACKET_SENT_IRQ`) is provided to indicate users when the packet has been completely sent by the DSI complex I/O. The `PACKET_SENT_IRQ` can be monitored in `DSI_VCn_IRQSTATUS[2]` `PACKET_SENT_IRQ` status bit. Users can request BTA even if the space allocated in the TX FIFO for the corresponding VC is empty. It can be sent later on even if there was no packet sent before BTA request. The `DSS.DSI_VCn_CTRL[6]` `BTA_EN` bit should be reset by hardware if the BTA request has been sent even if the automatic mode for this specific type of packets is enabled.

The bus turnaround is supported for video mode packets and for command mode packets. It is not possible to send BTA during the blanking periods of the video mode when HS blanking packets should be sent, that is, when one of the following bits is set to 1:

- `DSS.DSI_CTRL[20]` `BLANKING_MODE`
- `DSS.DSI_CTRL[21]` `HFP_BLANKING_MODE`
- `DSS.DSI_CTRL[22]` `HBP_BLANKING_MODE`
- `DSS.DSI_CTRL[23]` `HSA_BLANKING_MODE`

Therefore, in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

TA Timer

When TurnRequest signal is asserted (always only for data lane #1), the `TA_TO` timer is started. If the direction signal is no changed according to the turn-around request, the `TA_TO` interrupt is generated. When the Direction signal is in output mode, any data on the input data bus should be ignored since the DSI is in transmission mode (data and triggers should be ignored). See [Section 7.4.3.7.3](#) for more details on the `TA_TO` timer.

7.4.3.9 PHY Triggers

The DSI protocol engine uses three triggers, which are supported only for data lane 1:

- Reset from host to display
- Tearing effect (TE) from display to host
- Acknowledge from display to host

CAUTION

Each trigger is associated with a dedicated user-configurable receive or transmit pattern, loaded in [DSI_PHY_REGISTER3](#) or [DSI_PHY_REGISTER4](#) bit fields. The default (reset) values of the bit fields are aligned with the MIPI D-PHY specification v0.92. If the user needs to change any of these values, the following must be considered:

- If any of the bit fields are written with a nondefault value, the other bit fields in the same register must also be configured with different values. This is to ensure that two different trigger bit fields are not programmed with the same pattern.
- If two or more bit fields are written with equal values, this may lead to unpredictable behavior of the DSI PHY module.

7.4.3.9.1 Reset

The DSI protocol engine can use one of the triggers of the DSI_PHY to send a reset to the display. The reset trigger pattern is configurable through the [DSI_PHY_REGISTER3](#)[31:24] REG_TXTRIGGERESC3 bit field. To send the reset pattern to the peripheral, the DSS.[DSI_CTRL](#)[5] TRIGGER_RESET bit must be set to 1. When the software requires the trigger reset pattern to be sent, the DSI protocol engine resets its own logic but not the registers. The software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already taken into account for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is only valid if there is VC using the video mode and if it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on VP after the current frame are ignored.

To select the reset mode, software users must program the DSS.[DSI_CTRL](#)[14] TRIGGER_RESET_MODE.

CAUTION

For both reset modes, the hardware should flush the FIFOs, synchronization buffers, and line buffers before resetting the DSS.[DSI_CTRL](#)[0] IF_EN bit.

7.4.3.9.2 Tearing Effect

The TE on the display is avoided by having synchronization information from the display. It is used only in command mode. In case of video mode, it is not functional. Users are responsible for selecting the command mode for the VC using the TE feature.

The software must set and send the appropriate sequence to receive the TE trigger pattern from the peripheral. The value of the expected TE trigger pattern can be configured through the [DSI_PHY_REGISTER4](#)[23:16] REG_RXTRIGGERESC2 bit field. When the TE trigger pattern is received, the DSI protocol engine generates the TE_TRIGGER_IRQ interrupt with TE event if the interrupt is enabled. To enable the interrupt, set to 1 the DSS.[DSI_IRQENABLE](#)[16] TE_TRIGGER_IRQ_EN bit. The DSS.[DSI_IRQSTATUS](#)[16] TE_TRIGGER_IRQ status bit indicates if the interrupt event has been generated.

One or multiple VCs can be synchronized using the same TE trigger. The DSS.DSI_VCn_TE[30] TE_EN bit should be set to indicate that the hardware should use the following TE trigger to start the transfer of the data from the related VC. This bit is reset when all the data have been sent to the peripheral. The DSS.DSI_VCn_TE[31] TE_START bit should be used when the automatic mode enabled by setting the DSS.DSI_VCn_TE[30] TE_EN bit is not used. It allows users to start the transfer manually based on application events or based on the TE trigger interrupt (TE_TRIGGER_IRQ).

The number of bytes to be transferred is defined by using the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field. The TE_SIZE bit field is decremented for each payload byte (it does not include Check-sum) sent on the DSI link. The register content should not be modified by software during a transfer. The DSS.DSI_VCn_TE[15:0] TE_SIZE bit field should be set first to indicate that the following accesses to DSS.DSI_VCn_LONG_PACKET_HEADER register should be used for TE transfer.

The data can be provided from two sources (selection by setting the DSS.DSI_VCn_CTRL[1] SOURCE bit):

- L4 interconnect port using DMA request: The DMA request DSI_DMA_REQi (i=0 to 3) to should be asserted only when TE trigger is received or when the DSS.DSI_VCn_TE[31] TE_START bit is set by user and should not be asserted anymore when all the bytes defined in DSS.DSI_VCn_TE[15:0] TE_SIZE bit field have been sent on the DSI link. The VC is associated with a DMA request (from DSI_DMA_REQ0 to DSI_DMA_REQ3) by programming the number in the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field. The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide the number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field (the check-sum value is not provided in the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register). The size of the header is not taken into account in the number of bytes to transfer. The DSS.DSI_VCn_SHORT_PACKET_HEADER register is not used.
- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. In case there is no line buffer instantiated (that is, DSS.DSI_CTRL[13:12] LINE_BUFFER bit field set to 0), it is not possible to use the video port to provide data. The line buffer should be filled up according to the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register header. The value should be written before the TE trigger event is received or before the DSS.DSI_VCn_TE[31] TE_START bit is set to 1 by software. In case the total number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is not a multiple of the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register, all the packets have the same size defined by the WC of the header except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Since the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is modified after each packet transfer, the size of the last packet is equal to the value of DSS.DSI_VCn_TE[15:0] TE_SIZE bit field just before the last transfer (the header and the payload check-sum sizes are not included in DSS.DSI_VCn_TE[15:0] TE_SIZE bit field).

When the transfer is completed, the value of the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is equal to 0. The software must ensure that the pending data in the TX FIFO for the corresponding VC using TE are related to TE transfer. Any data in the TX FIFO that should be sent before reception of TE trigger should be sent before TE. This is done by not enabling TE trigger until all data for the corresponding VC have been sent to the peripheral. The software can check that the space allocated for the VC in the TX FIFO is empty by reading the DSS.DSI_VCn_CTRL[5] TX_FIFO_NOT_EMPTY status bit.

7.4.3.9.3 Acknowledge

The corresponding Acknowledge interrupt (ACK_TRIGGER_IRQ) is generated upon reception of the acknowledge trigger. The value of the expected acknowledge trigger pattern can be configured through the DSI_PHY_REGISTER4[15:8] REG_RXTRIGGERESC1 bit field. To enable the acknowledge interrupt, set the DSS.DSI_IRQENABLE[17] ACK_TRIGGER_IRQ_EN bit to 1. When the interrupt is generated, the DSS.DSI_IRQSTATUS[17] ACK_TRIGGER_IRQ status bit is set to 1.

7.4.3.10 ECC Generation

The DSI protocol uses a four-byte packet header. Since ECC generation requires a fixed word length of 64-bits, the packet headers should be padded with additional bits to form a full eight-byte value for ECC generation and checking. The packet header less the ECC byte should occupy bits D[23:0] and the pad bits should occupy bits D[63:24]. All padding bits should be zero for the purpose of generating the ECC byte. ECC can be generated using a parallel approach as illustrated in Figure 7-100.

Figure 7-100. 64-Bit ECC Generation on TX Side

dss-176

The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.DSI_CTRL[2] ECC_RX_EN bit enables/disables the ECC generation in the receive direction.
- The DSS.DSI_VcN_CTRL[8] ECC_TX_EN bit enables/disables the ECC generation in the transmit direction

7.4.3.11 Checksum Generation for Long Packet Payloads

Long packets are comprised of a packet header protected by an ECC byte and a payload of 0 to $2^{16} - 1$ bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. Note that, for the special case of a zero-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations since the peripheral has no way for reporting errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets to peripherals. It is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation should transmit two bytes having value 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor should disable checksum checking for received long packets from peripherals that do not support checksum generation.

The checksum should be realized as a 16-bit CRC with a generator polynomial of $x^{16}+x^{12}+x^5+x^0$. The LS byte is sent first, followed by the MS byte. Note that within the byte, the LS bit is sent first.

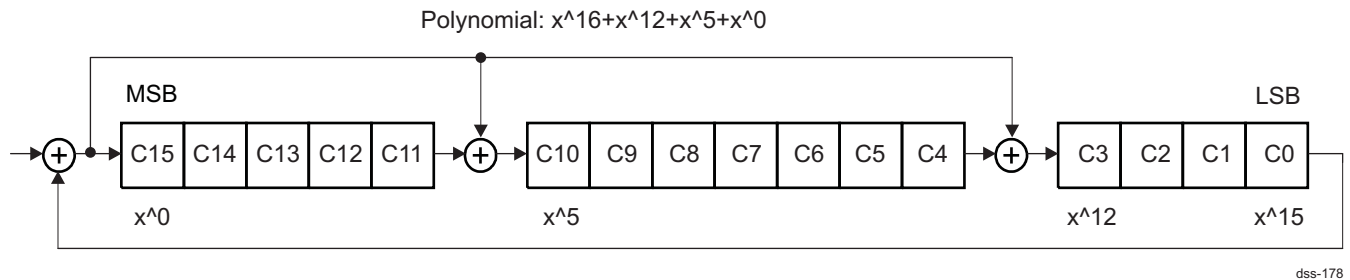

Figure 7-101. Checksum Transmission

dss-177

The CRC implementation is presented in [Figure 7-102](#). The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the packet header then enters as a bitwise data stream from the left, LS bit first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the checksums MSB and C0 the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

Figure 7-102. 16 Bit CRC Generation Using a Shift Register

The check-sum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.DSI_CTRL[1] CS_RX_EN bit enables/disables the check-sum generation in the receive direction.
- The DSS.DSI_VCn_CTRL[7] CS_TX_EN bit enables/disables the check-sum generation in the transmit direction

7.4.3.12 End of Transfer Packet

To allow the DSI protocol (rather than the DSI_PHY) at the display to detect the HS End Of Transfer (EOT), an EOT packet type is added. It is a fixed short packet (4 bytes) that is added at every HS-to-LP transition. This function is enabled by the DSI_CTRL[19] EOT_ENABLE bit.

The EOT packet has a fixed format:

- Data Type = DI [5:0] = 0b001000
- Virtual Channel = DI [7:6] = 0b00
- Payload Data [15:0] = 0x0F0F
- ECC [7:0] = 0x01

When more than one data lane is used, the bytes in the EOT packet are distributed across multiple lanes. EOT packet generation is supported only for the end of HS transmissions. No EOT packet is added at the end of LP transmissions. For LP reception, any EOT packet received is simply passed through the same as any other packet, but no internal decode or use is made of the EOT information.

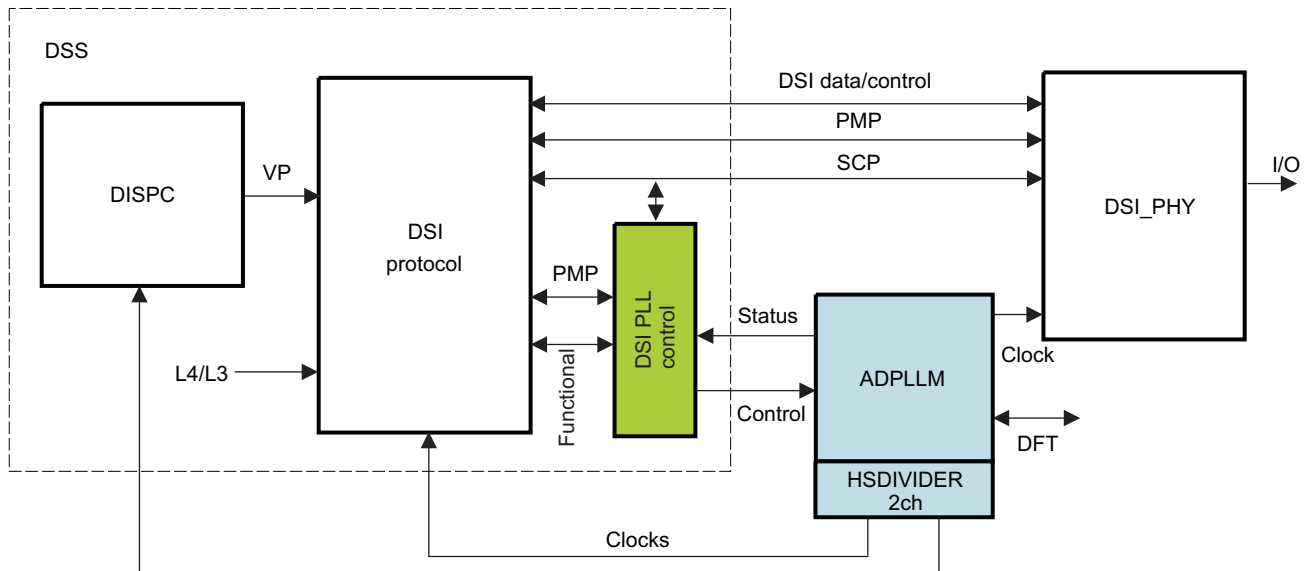

7.4.4 DSI PLL Controller Functionalities

7.4.4.1 DSI PLL Controller Overview

The DSI PLL controller module forms part of the display sub-system. Nevertheless, it uses the SCP (Serial Configuration Port) and PMP (Power Management Port) ports as the primary interfaces to the DSI protocol engine. The SCP interface is used to set the configuration of the DPLL and HSDIVIDER modules, primarily the various counter values. The PMP port is used to control the power state of the DPLL and HSDIVIDER modules. [Figure 7-103](#) provides an overview of the DSI PLL controller module inside the display subsystem.

The DSI PLL is also used to generate the 74.25-MHz frequency used for HDTV applications.

Figure 7-103. DSI PLL Controller Overview

dss-179

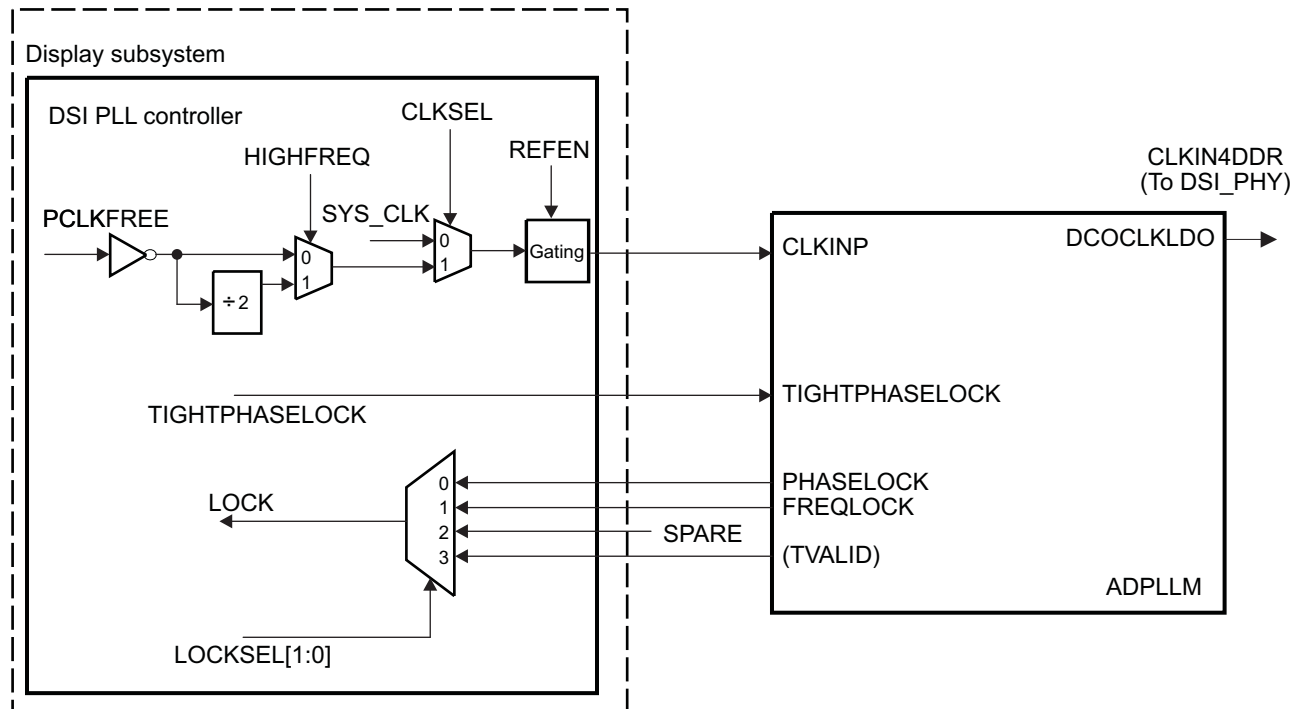

NOTE: The DSI PLL controller module does not have an interface to L4 interconnect. The programmable features are managed by registers mapped into the DSI protocol engine.

7.4.4.2 DSI PLL Controller Architecture

The DSI PLL is an ADPLL module. The pixel clock (PCLK) frequency range is 2 to 68.25 MHz. This may be divided by 2. This is performed by setting the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 1.

Figure 7-104 shows the internal DSI PLL reference diagram.

Figure 7-104. DSI PLL Reference Diagram

camdss-180

NOTE: PCLK is inverted as the falling edge is the reference edge and ADPLL uses positive edge as reference (F/F should be positive edge clock also).

The DSI PLL clock output corresponds to the CLKIN4DDR clock of the DSI complex I/O module.

The DSI PLL reference clock is the DSI_PLL_REFCLK clock. Depending on the setting in `DSS.DSI_PLL_CONFIGURATION2[11]` `DSI_PLL_CLKSEL` bit, the reference clock can be either the `DSS2_ALWON_FCLK` provided by the PRCM or the `PCLKFREE` provided by the DISPC module.

7.4.4.3 DSI PLL Operations

The signals of the DSI PLL configuration operate according to [Table 7-37](#). The values in the table indicate the operation when the PLL is not locked.

Table 7-37. DSI PLL Operation Modes When Not Locked

DSI PLL Operation Mode	Stop mode Low power ⁽¹⁾	Stop mode Fast Relock ⁽¹⁾	Idle bypass
Mode Description	Output clocks stopped Lowest power standby	Output clocks stopped Fastest start-up time	Selects when PLL and HSDIVIDER bypass clocks are used
<code>DSS.DSI_PLL_CONFIGURATION2[0]</code> <code>DSI_PLL_IDLE</code>	0	0	1
<code>DSS.DSI_PLL_CONFIGURATION2[6]</code> <code>DSI_PLL_LOWCURRSTBY</code>	1	0	1
<code>DSS.DSI_PLL_CONFIGURATION1[0]</code> <code>DSI_PLL_STOPMODE</code>	1	1	X

⁽¹⁾ Recommended

When locked, the PLL output frequency is: $[(2xREGM)/(REGN + 1)]x[CLKin(MHz)/(HIGHFREQ + 1)]$ where:

- M multiplier is programmed in `DSS.DSI_PLL_CONFIGURATION1[18:8]` `DSI_PLL_REGM` bit field.
- N divider is programmed in `DSS.DSI_PLL_CONFIGURATION1[7:1]` `DSI_PLL_REGN` bit field.
- HIGHFREQ divider by 2 is enabled by setting the `DSS.DSI_PLL_CONFIGURATION2[12]`

DSI_PLL_HIGHFREQ bit to 1.

7.4.4.4 DSI PLL Controller Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register space using SCP port. This includes all the configuration signals and the returning status signals.

CAUTION

All writes must be 32-bit operations as the SCP always transfers 32 bits. Any 16-bit or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations may optionally be updated in synchronism with the display controller (DISPC) and DSI protocol engine. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must have been written before this signal is asserted. See [Section 7.4.3.5.1](#) for more details.

7.4.4.5 Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

7.4.5 DSI Complex I/O Functionalities

7.4.5.1 DSI Complex I/O Overview

DSI_PHY is a complex I/O with 3 unidirectional (HS) Lane Modules. This includes 2 data lane modules and 1 clock lane module. Each lane module has 2 data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using point to point interconnect.

Lane modules support high-speed burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes maybe used for Low Power Data Transmission, among other things.

The maximum data rate supported is 900 Mbps per data lane. The lane module function and position is configurable, that is, any lane module can be chosen as clock lane module, and DX/DY data pad for each lane module can be configured as either DP or DN pins defined by DSI_PHY spec.

DSI_PHY interacts with the higher layers of the DSI link through the PHY-Protocol Interface (PPI). DSI_PHY does not include a PLL; a high frequency clock input is expected in HS mode (CLKIN4DDR). DSI_PHY supports also Serial Configuration Protocol (SCP) to set various configuration and control registers. The DSI_PHY supports GPIO operation on each of the six data pins.

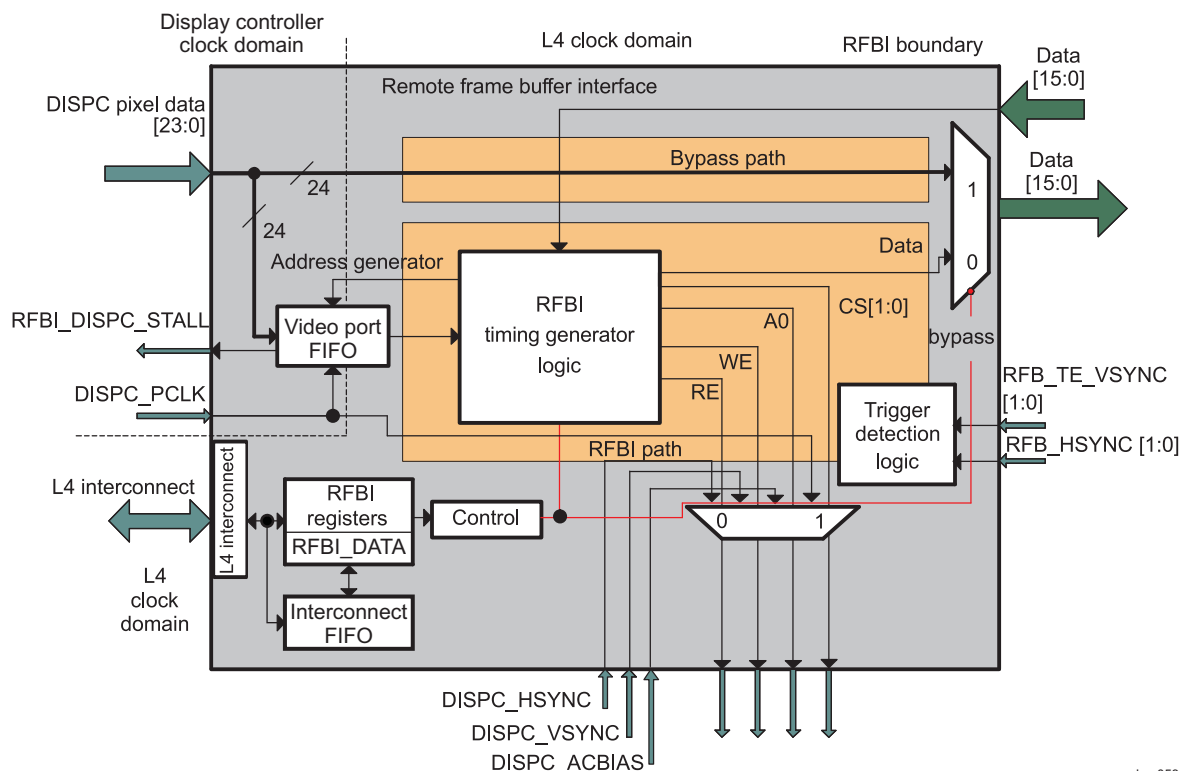

7.4.6 RFB Functionalities

The RFB module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFB module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment independently of the endianness in system memory.

Figure 7-105 shows an overview of the RFB architecture.

Figure 7-105. RFB Architecture Overview

dss-053

7.4.6.1 RFB FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFB and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. [Section 7.4.6.4, Output Parallel Modes](#), shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

7.4.6.2 RFB Interconnect FIFO

The interconnect FIFO receives the data from [RFB_DATA](#) write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFB and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of [RFB_DATA](#)).

7.4.6.3 Input Pixel Formats

The supported pixel formats in the RFB module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

7.4.6.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format ($i = 0$ or 1) (see also [Table 7-38](#)):

- The DSS.RFBI_CONFIG $_i$ [10:9] CYCLEFORMAT bit field is set to 0x3 (three cycles for two pixels).
- The DSS.RFBI_DATA_CYCLE1 $_i$ register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI_DATA_CYCLE2 $_i$ register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI_DATA_CYCLE3 $_i$ register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

Table 7-38. 16-Bit Interface Configuration/24-Bit Mode

	24-Bit Mode		
	1st Cycle	2nd Cycle	3rd Cycle
Data[15]	R0[7]	B0[7]	G1[7]
Data[14]	R0[6]	B0[6]	G1[6]
Data[13]	R0[5]	B0[5]	G1[5]
Data[12]	R0[4]	B0[4]	G1[4]
Data[11]	R0[3]	B0[3]	G1[3]
Data[10]	R0[2]	B0[2]	G1[2]
Data[9]	R0[1]	B0[1]	G1[1]
Data[8]	R0[0]	B0[0]	G1[0]
Data[7]	G0[7]	R1[7]	B1[7]
Data[6]	G0[6]	R1[6]	B1[6]
Data[5]	G0[5]	R1[5]	B1[5]
Data[4]	G0[4]	R1[4]	B1[4]
Data[3]	G0[3]	R1[3]	B1[3]
Data[2]	G0[2]	R1[2]	B1[2]
Data[1]	G0[1]	R1[1]	B1[1]
Data[0]	G0[0]	R1[0]	B1[0]

7.4.6.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

7.4.6.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

7.4.6.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

7.4.6.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WR signal), RE (RFBI_RD signal), and CSx (RFBI_CSx signal, with x = 0, 1) is programmable.

Table 7-39 describes the read/write function.

Table 7-39. Read/Write Function Description

A0 (RFBI_A0)	WE (RFBI_WR)	RE (RFBI_RD)	Function Description
1	0	1	Display data write, parameter data write
1	1	0	Display data read
0	1	0	Status read
0	0	1	Command data write

A minimum of RFBI_Cs cycle time, as defined in Table 7-40, is required to keep the RFBI_CSx signal asserted between write transfers of multiple pixels.

Table 7-40 indicates the minimum cycle time for RFBI_CSx, depending on the source of pixels (display controller or L4 interconnect slave port) and the cycle format (1 pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

Table 7-40. Minimum Cycle Time for CSx/WE Always Asserted

RFBI Performance	RFBI_CONFIGi[10:9] CYCLEFORMAT	RFBI_CONFIGi[8:7] L4FORMAT	Minimum Cycle Time (in Number of L4 Cycles)
L4 interconnect	1 pixel/cycle	1 pixel	5
	1 pixel/2 cycles	1 pixel	4
	1 pixel/3 cycles	1 pixel	4
	2 pixels/3 cycles	1 pixel	6
	1 pixel/cycle	2 pixels	4
	1 pixel/2 cycles	2 pixels	4
	1 pixel/3 cycles	2 pixels	4
	2 pixels/3 cycles	2 pixels	6
Display Controller	1 pixel/cycle	N/A	4
	1 pixel/2 cycles	N/A	3
	1 pixel/3 cycles	N/A	3
	2 pixels/3 cycles	N/A	6

7.4.7 Video Encoder Functionalities

The input formats supported by the encoders are 24-bit 4:4:4 RGB. The encoder output is the DAC stage (for more information, see Section 7.2, *Display Subsystem Environment*). In the display subsystem, the input format from the display controller is always 24-bit RGB. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data to 24-bit YCbCr data.

The remaining Cb and Cr color components enter the 2-to-1 chrominance decimation, which reduces by half the chrominance bandwidth and the amount of chrominance data. After the data manager, the encoder processes in 4:2:2 data path up to the 2x interpolation. A luma delay synchronizes luma to chrominance data.

Figure 7-106 shows an overview of the video encoder architecture.

Figure 7-106. Video Encoder Architecture Overview

camdss_swpu176-public-079

NOTE: Output video mode can be either composite video (CVBS output) or separate video (S-video: Luma and Chroma outputs):

- Composite video: only AVDAC1 is used
- Separate video (Luma/Chroma): Both AVDAC1 (Luma) and AVDAC2 (Chroma) are used
The selection is programmed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit. Composite video is the default selection.

7.4.7.1 Test Pattern Generation

For diagnostic purposes, the data manager can be forced to output 100/100 color bar RGB/YCbCr data by setting the SVDS field VENC_F_CONTROL[7:6] register to 0x1.

Table 7-41. 100/100 Color Bar Table

COLOR	R	G	B	Y	Cb	Cr
White	255	255	255	235	128	128
Yellow	255	255	0	210	16	146
Cyan	0	255	255	170	166	16
Green	0	255	0	145	54	34
Magenta	255	0	255	106	202	222
Red	255	0	0	81	90	240
Blue	0	0	255	41	240	110
Black	0	0	0	16	128	128

7.4.7.2 Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the DSS.VENC_GAIN_Y register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the DSS.VENC_BLACK_LEVEL and DSS.VENC_BLANK_LEVEL registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

7.4.7.3 Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the DSS.VENC_GAIN_U and DSS.VENC_GAIN_V register bits.

7.4.7.4 Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$$S_CARR = \text{ROUND} ([F_{sc}/F_{clkenc}] \times 2^{32})$$

where:

F_{sc} = Frequency of the subcarrier

F_{clkenc} = Frequency of the internal video encoder

The DSS.VENC_S_CARR register controls the subcarrier frequency. The DSS.VENC_C_PHASE register controls the phase of the subcarrier. The phase of the color subcarrier is reset to DSS.VENC_C_PHASE. Table 7-42 presents the VENC_S_CARR register values depending the standard and pixel type used.

Table 7-42. VENC_S_CARR Register Recommended Values

Standard	Pixel Type	Subcarrier Frequency (Fsc) (MHz)	Fclkenc (MHz)	VENC_S_CARR register value (hexa)
NTSC-M, J	ITU-R601	3.579545	27	0x21F07C1F
PAL-M	ITU-R601	3.5756083125	27	0x21E6EFE3
PAL-B, D, G, H, I	ITU-R601	4.43361875	27	0x2A098ACB
NTSC-M, J	Square pixel	3.579545	24.5454	0x25555555
PAL-M	Square pixel	3.579561149	24.5454	0x1F15C01E
PAL-B, D, G, H, I	Square pixel	4.43361875	29.50	0x26798C0C

CAUTION

In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset

- Reset every two lines
- Reset every two fields
- Reset every eight fields

The DSS.VENC_C_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The DSS.VENC_BSTAMP_WSS_DATA[6:0] BSTAP bit field sets the amplitude of the color burst. The DSS.VENC_M_CONTROL[1] PAL bit enables phase alternation line encoding.

A phase switching subcarrier is generated to encode the chrominance signal when the DSS.VENC_M_CONTROL[1] PAL bit is set to 1. Otherwise, a normal subcarrier is generated. Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Two possible alternation sequences are possible, and the DSS.VENC_M_CONTROL[5] PALPHS bit selects one of these sequences.

7.4.7.5 Closed Caption Encoding

The encoder can be programmed to encode closed-caption data and extended data in the selected line. The closed-caption data are sent to the encoder through the L4 interconnect. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see [Table 7-43](#)).

Table 7-43. Closed-Caption Data Format

MSB						LSB	
Bit6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Odd parity

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[0] bit enables closed-caption encoding in odd fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[1] bit enables closed-caption encoding in even fields.

To select the scan line where the CC data are encoded, program the VENC_LN_SEL[4:0] SLINE bit field.

CAUTION

The setting of the value of the SLINE[4:0] bit field depends on the video standard:

- PAL mode: Because there is a one-line offset, program the desired line number – 1. To activate the closed caption on line 21 (0x15), program the value $0x15 - 1 = 0x14$. The default value is $0x15 + 1 = 0x16$ (line 22).
- NTSC mode: Because there is a four-line offset, program the desired line number – 4. To activate the closed caption on line 21 (0x15), program the value $0x15 - 4 = 0x11$. The default value is $0x15 + 4 = 0x19$ (line 25).

The DSS.VENC_LN_SEL[25:16] LN21_RUNIN bit field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The DSS.VENC_LINE21[15:8] L21O and DSS.VENC_LINE21[7:0] L21O bit fields contain the first and the second bytes, respectively, of closed-caption data to be encoded in the odd field. The DSS.VENC_LINE21[31:24] L21E and DSS.VENC_LINE21[23:16] L21E bit fields contain the first and the second bytes, respectively, of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (DSS.VENC_STATUS[4] CCE or DSS.VENC_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the DSS.VENC_STATUS[4] CCE bit or the DSS.VENC_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in [Figure 7-107](#), a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC bit field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xfline) for NTSC-601. The closed-caption running clock common frequencies are detailed in [Table 7-44](#).

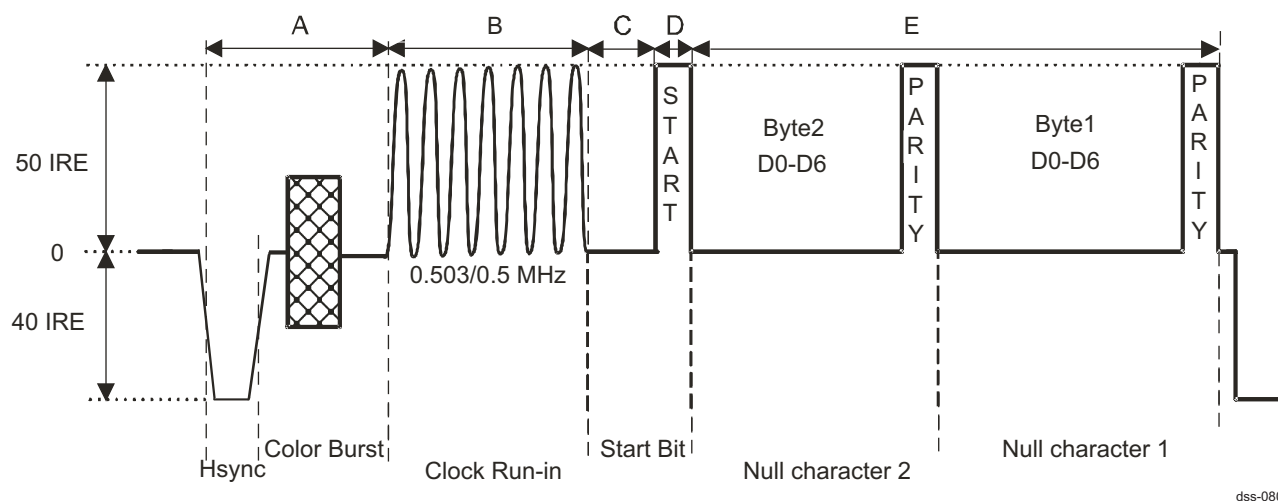

Table 7-44. Closed-Caption Run Clock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[15:0] FCC bit field value	0x2631	0x25ED	0x2A03	0x22B6

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows: 0 = 0 IRE; 1 = 50 IRE.

[Figure 7-107](#) shows the parameters of closed-caption line data implemented in different standards.

Figure 7-107. Closed Captioning Timing

NOTE:

- The interval A is controlled by the DSS.VENC_LN_SEL[25:16] LN21_RUNIN bit field.
- The interval B is controlled by DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC bit field.

Table 7-45. Closed-Caption Standard Timing Values

Intervals	Description	Timing Values for Encoding			Timing Values for Decoding		
		Minimal	Nominal	Maximal	Lower Bound	Nominal	Upper Bound
A	HSYNC to clock running	10.250 μ s	10.500 μ s	10.750 μ s	10.000 μ s	10.500 μ s	11.000 μ s
B	Clock running		12.910 μ s			12.910 μ s	
C	Clock running to third start bit		3.972 μ s			3.972 μ s	
D	Start bit		1.986 μ s			1.986 μ s	
E	Data characters		31.778 μ s			31.778 μ s	

NOTE: All timing values listed in [Table 7-45](#) are measured from the mid-point (half amplitude) on all edges.

For a complete description of copy protection including CGMS-A, please refer to CEA-608-x standard

7.4.7.6 Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval.

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the DSS.VENC_L21_WC_CTL[14:13] EVEN_ODD_EN bit and by programming the VENC_BSTAMP_WSS_DATA[27:8] WSS_DATA bit field.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field. The wide-screen signaling running clock common frequencies are detailed in [Table 7-46](#)

Table 7-46. Wide-Screen Signaling Run Clock Frequency Settings

	NTSC-601	PAL-601	NTSC Square Pixel	PAL Square Pixel
VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field value	0x043F	0x2F72	0x04AC	0x2B6D

To select the line where the WSS data are encoded, program the DSS.VENC_L21_WC_CTL[12:8] LINE bit field.

CAUTION

The setting of the LINE[12:8] bit field value depends on the video standard:

- PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line $0x16 + 1 = 0x17$ (23rd line). Note that the default value is $0x14 + 1 = 0x15$ (21st line).
- NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line $0x10 + 4 = 0x14$ (20th line). Note that the default value is $0x14 + 4 = 0x18$ (24th line).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in [Figure 7-108](#).

Figure 7-108. WSS Timing

dss-081

7.4.7.7 Video DAC Stage – Architecture and Control

Figure 7-109 shows the architecture of the video DAC stage, comprising two 10-bit video DACs (AVDAC1 and AVDAC2) instances.

Figure 7-109. Video DAC Stage Architecture

dss-082

The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays (TV sets). Two (one per channel) 10-bit current steering AVDACs are used to generate the video analog signal:

- AVDAC1: Carries either the CVBS (composite) or S-Video Luma (Y) analog TV outputs; it provides also the TV detection/disconnection and power-down mode features.
- AVDAC2 : Carries only the S-Video Chroma (C) analog TV output.

The device system control module provides two dedicated AVDAC registers, CONTROL.CONTROL_AVDAC1 and CONTROL.CONTROL_AVDAC2, to configure the respective channels through the following bit field:

- CONTROL.CONTROL_AVDACx [20:16] AVDACx_COMP_EN: Allows direct control over the configuration of the analog TV output. See Table 7-47, Section 7.5.8, Video Encoder Basic Programming Model, and Chapter 13, System Control Module.

Table 7-47. Analog TV Output Control

Register CONTROL.CONTROL_AVDACx [x=1, 2]	Description
[19] AVDACx_COMP_EN	Single or dual channel operation 0: Single channel (default) 1: Dual channel
[18] AVDACx_COMP_EN	Channel role 0: Luma video channel (dual-channel configuration) or Composite video channel (single-channel configuration) (default) 1: Chroma video channel (dual-channel configuration)

Table 7-47. Analog TV Output Control (continued)

Register CONTROL.CONTROL_AVDACx [x=1, 2]	Description
[17] AVDACx_COMP_EN	Full scale swing selection 0: High full-scale output swing: 1.3 V (default) 1: Low full-scale output swing: 0.88 V
[16] AVDACx_COMP_EN	Current reference selection 0: External current reference (set by external resistor connected to <i>cvideo1_rset</i> pin) (default) 1: Internal current reference

CAUTION

Any change to the control register must be done only when the respective VDAC is off.

High full-scale swing is the default mode. Low-swing mode does not comply with the NTSC and PAL video standards. It must be used only for backward compatibility to the OMAP35x.

7.4.7.8 Video DC/AC Coupled TV Load

The 10-bit video DAC stage supports both DC-coupled and AC-coupled TV loads. The CONTROL.CONTROL_DEVCONF1[11] TVACEN bit is used to define which output coupling is used (0: DC coupling; 1: AC coupling). This bit is the first one to be programmed according to the TV load on the PCB board.

NOTE: In high-swing mode, when DC coupling is used, there is a 180-mV DC offset at the TVOUT output (*cvideo1_out* for AVDAC1 and *cvideo2_out* for AVDAC2).

In low-swing mode, when DC coupling is used, the DC offset at the maximum DAC code (@Max DAC current ~500 μ A) is 300 mV.

7.4.7.9 TV Detection/Disconnection Pulse Generation and Usage**7.4.7.9.1 TV Detection/Disconnection Pulse Generation**

The TV detect block is an integral part of the video DAC stage.

NOTE:

- The TV detection/disconnection feature is supported only for AVDAC1.
- The TV disconnection feature is recommended to save power. The TV detection/disconnection is operational only when video out is active. Therefore, to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.

This block compares the output of AVDAC1 (*cvideo1_out*) to a reference, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit if the load is AC or DC coupled to adjust accordingly. To enable the detection of the load, the video encoder generates a negative TVDET pulse aligned with the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending on the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status, given by the TVINT output bit, is read later with the TVDET pulse rising edge. The TVINT signal of AVDAC1 is internally connected to channel 1 of the GPIO2 module, mapped as the TV detector interruption.

The following registers are used to set the TV detection/disconnection pulse:

- The DSS.VENC_TVDETGP_INT_START_STOP_X register defines which pixels are used to start and stop the pulse inside their respective line.
- The DSS.VENC_TVDETGP_INT_START_STOP_Y register defines which lines are used to start and stop the pulse.
- The DSS.VENC_GEN_CTRL[0] EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The DSS.VENC_GEN_CTRL[16] TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

7.4.7.9.2 TV Detection Procedure

The TV detection procedure is the following:

1. Initial setup:
 - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
3. Set the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 1 to enable the video DAC1 output.
4. Power up the vdda_dac voltage for the DAC stage and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC.
5. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
6. Check the TVINT output signal: When TVINT is set to 1, the load is connected.

CAUTION

- If AC coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If DC coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

7.4.7.9.3 TV Disconnection Procedure

The TV disconnection procedure is the following:

1. Initial setup:
 - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y

- registers.
- The TVDET pulse is set high by hardware according to the settings in the `DSS.VENC_TVDETPGP_INT_START_STOP_X` and `DSS.VENC_TVDETPGP_INT_START_STOP_Y` registers.
 - Check the TVINT output signal: When TVINT is reset to 0, the load is disconnected.
 - Reset the `VENC_OUTPUT_CONTROL[0]` LUMA_ENABLE bit (in s-video mode) or the `VENC_OUTPUT_CONTROL[1]` COMPOSITE_ENABLE (in composite video mode) to 0 to disable the video DAC1 output.
 - Power-down the `vdda_dac` voltage for the DAC stage and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC.

CAUTION

- If DC coupling is selected, two TVDET pulses are required to set low the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If AC coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

7.4.7.9.4 Recommended TV Detection/Disconnection Pulse Waveform

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. As explained in [Section 7.4.7.9.2, TV Detection Procedure](#), and in [Section 7.4.7.9.3, TV Disconnection Procedure](#) by using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is T_{dm} , which should be longer than the delay through the AVDAC and TVOUT buffer, which is at least 750 ns.

If DC-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. [Figure 7-110](#) shows the waveforms for the DC-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 7-110. DC-Coupling TV Detect Waveforms for TV Connected and Disconnected

dss-083

If AC-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. [Figure 7-111](#) shows the waveforms for the AC-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 7-111. AC-Coupling TV Detect Waveforms for TV Connected and Disconnected

NOTE:

- When setting the DSS.VENC_TVDETPGP_INT_START_STOP_X register, software users must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the cvideo1_out output signal.

7.4.7.9.5 TV Detection/Disconnection Usage

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for ac and for dc operation. For DC operation, the cvideo1_out voltage is compared against a voltage reference that makes the comparator trigger in each sync pulse while the load is connected. For AC operation, the cvideo1_out voltage is compared against a voltage reference that makes the comparator trigger in each sync pulse while the load is disconnected. In both cases, the TVINT output signal produces a logic 1 when a load is connected and a logic 0 when a load is disconnected.

For DC-coupling mode, see [Figure 7-112](#) and for AC-coupling mode, see [Figure 7-113](#).

NOTE:

Because the video DAC stage and the video encoder must be awake for connection detection, consider that the video DAC stage can take up to 10 μs to wake up.

Figure 7-112. GPIO Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode**Figure 7-113. GPIO Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode**

7.4.7.10 Video DAC Stage Bypass Mode

The 10-bit video DAC stage has a TVOUT buffer bypass mode that turns off the TVOUT buffers and redirects directly the outputs of the DACs to the VFB pins (cvideo1_vfb for AVDAC1 and cvideo2_vfb for AVDAC2).

This bypass mode is activated by setting the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit to 1. The reset value of the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

NOTE: In bypass mode:

- The cvideo1_rset pin requires a Rset resistor connected to the ground. The typical value of the Rset resistor is 10K.
- Both cvideo1_vfb and cvideo2_vfb pins require a Rout resistors connected to the ground. The typical values of Rout1 and Rout2 resistors are 1,5K.

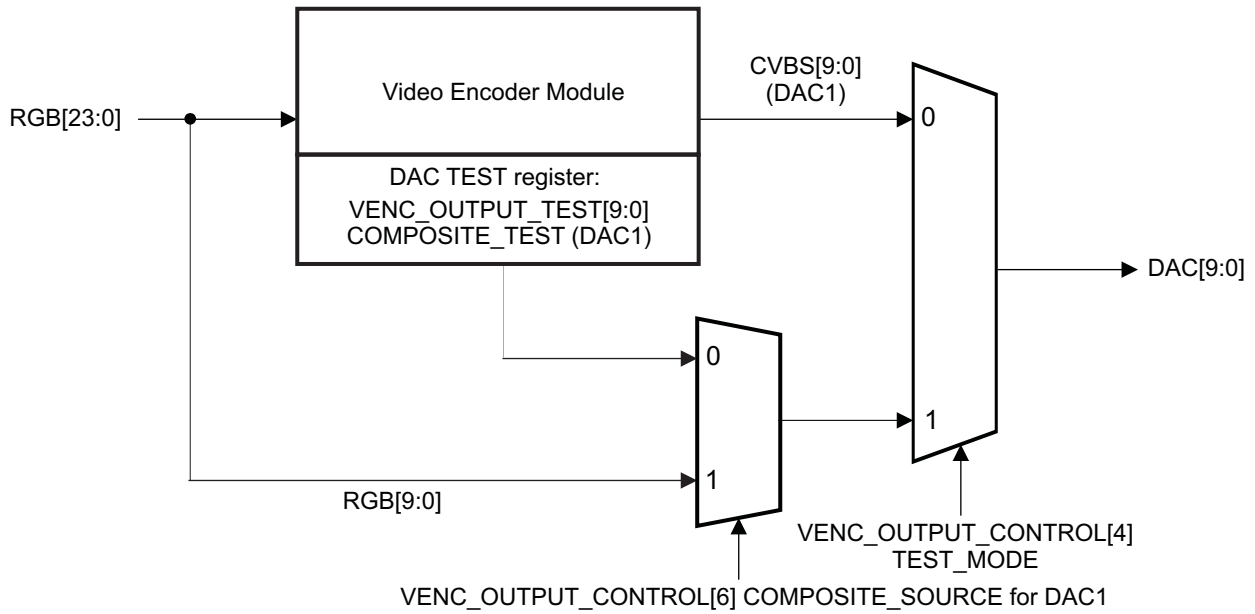

CAUTION

- The TV detect feature is not available in bypass mode.
- In bypass mode, an external amplifier is needed on the cvideo1_vfb and cvideo2_vfb pins.

7.4.7.11 Video DAC Stage Test Mode

The DAC stage can be tested for debug using either 10-bit external data or 10-bit internal register values directly connected to the DACs. See [Figure 7-114](#) for video DAC test in composite video mode, and see [Figure 7-115](#) for video DAC test in separate video mode.

Figure 7-114. DAC Test Mode in Composite Video Mode

dss-087

Figure 7-115. DAC Test Mode in Separate video Mode

dss-088

- Use the DSS.VENC_OUTPUT_CONTROL[4] TEST_MODE bit to select between DAC normal mode (0x0) and DAC test mode (0x1).
- Use the DSS.VENC_OUTPUT_CONTROL[7] CHROMA_SOURCE bit for AVDAC2 and either the DSS.VENC_OUTPUT_CONTROL[6] COMPOSITE_SOURCE bit (in composite video mode) or the DSS.VENC_OUTPUT_CONTROL[5] LUMA_SOURCE bit (in s-video mode) for AVDAC1 to select the test mode:
 - 0x0: From the internal register DSS.VENC_OUTPUT_TEST[25:16] CHROMA_TEST bit field for AVDAC2 and either DSS.VENC_OUTPUT_TEST[9:0] COMPOSITE_TEST bit field (composite video) or DSS.VENC_OUTPUT_CONTROL[25:16] LUMA_TEST (s-video mode) for AVDAC1
 - 0x1: From the video port G[1:0], B[7:0]

NOTE: In the external data test mode (bypass mode), the display controller must provide the data (G[1:0], B[7:0]) externally. To do this, configure the video encoder to generate correct timing signals, without which the display controller cannot operate (even if the encoder core is bypassed from the data path perspective).

7.4.7.12 Video DAC Stage Power Management

After device reset, the DSS_CONTROL[5] DAC_POWERDN_BGZ register bit is set to 0, and the video DAC stage is powered down.

Table 7-48 shows possible power management configurations and the corresponding register settings.

Table 7-48. Video DAC Stage Power Management

Power Management Controls						
	AVDAC2	AVDAC1				
DSS_CONTROL[5] DAC_POWERD N_BGZ	VENC_OUTPUT_ CONTROL[2] CHROMA_ENAB LE	VENC_OUTPUT_C ONTROL[1] COMPOSITE_ENA BLE	VENC_OUTPUT _CONTROL[0] LUMA_ENABL E	CONTROL_DEV CONF1[18] TVOUTBYPASS	CONTROL_D EVCONF1[11] TVACEN	Description
0	x	x	x	x	x	Total power down. Bandgaps powered down.
1	0	0	0	x	x	Standby (analog in power down except bandgaps/LDOs)
1	1	1	1	0	0	Full power up in DC mode
1	1	1	1	0	1	Full power up in AC mode
1	1	1	1	1	x	Full power up in TVOUT bypass mode (DAC-only mode)

7.5 Display Subsystem Basic Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)
 - Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support
 - Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support
 - Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.

7.5.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 0.
 - (a) Reset the frame done status bit by writing 1 in the DSS.DISPC_IRQSTATUS[0] FRAMEDONE bit.
 - (b) Wait until the DSS.DISPC_IRQSTATUS[0] FRAMEDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
 - PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit set to 1
 - PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit set to 1
 - PRCM.CM_FCLKEN_DSS[2] EN_TV bit set to 1
 - PRCM.CM_ICLKEN_DSS[0] EN_DSS bit set to 1

Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.DSS_SYSSTATUS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

7.5.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS_CONTROL[2] VENC_CLOCK_MODE bit and the DSS.DSS_CONTROL[3] VENC_CLOCK_X4 bit for TV set support.
3. To configure the top level of the DAC stage, set the DSS.DSS_CONTROL[4] DAC_DEMEN bit for TV set support (if required).
4. Configure the RFBI module and/or the video encoder as needed.
5. Configure the display controller.

7.5.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC_CONTROL[5] GOLCD bit is set for the LCD output and/or the DSS.DISPC_CONTROL[6] GODIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC_CONTROL[6] GODIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC_CONTROL[5] GOLCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC_CONTROL[5] GOLCD or DSS.DISPC_CONTROL[6] GODIGITAL bit, ensure that the bit is cleared.

Table 7-49 lists the shadow registers.

Table 7-49. Shadow Registers

Shadow Register Name	Updated on VFP Start Period (LCD output)	Updated on External VSYNC (Digital output)
DSS.DISPC_CONTROL	X ⁽¹⁾	X ⁽¹⁾
DSS.DISPC_CONFIG	X	X
DSS.DISPC_DEFAULT_COLOR_m (m = 0)	X	
DSS.DISPC_DEFAULT_COLOR_m (m = 1)		X
DSS.DISPC_TRANS_COLOR_m (m = 0)	X	
DSS.DISPC_TRANS_COLOR_m (m = 1)		X
DSS.DISPC_LINE_NUMBER	X	
DSS.DISPC_TIMING_H	X	
DSS.DISPC_TIMING_V	X	
DSS.DISPC_POL_FREQ	X	
DSS.DISPC_DIVISOR	X

DSS.DISPC_VIDn_PRELOAD	X	X
DSS.DISPC_DATA_CYCLEk (k = 0 to 3)	X	

7.5.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC_SYSCONFIG
- DSS.DISPC_SYSSTATUS
- DSS.DISPC_IRQSTATUS
- DSS.DISPC_IRQENABLE

7.5.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

7.5.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_GFX_BAj
- DSS.DISPC_GFX_ATTRIBUTES
- DSS.DISPC_GFX_ROW_INC
- DSS.DISPC_GFX_PIXEL_INC
- DSS.DISPC_GFX_FIFO_THRESHOLD
- DSS.DISPC_GFX_TABLE_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURSTSIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_GFX_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008,

respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

- Active matrix (TFT) display: `DSS.DISPC_GFX_PRELOAD[11:0]` PRELOAD = 0x60 (value is 96)
- Color passive matrix (STN) display: `DSS.DISPC_GFX_PRELOAD[11:0]` PRELOAD = 0x72 (value is 114)
- Monochrome passive matrix (STN) display: `DSS.DISPC_GFX_PRELOAD[11:0]` PRELOAD = 0xE0 (value is 224)
- Base address of the graphics buffer in system memory (`DSS.DISPC_GFX_BAj` registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register `DSS.DISPC_GFX_BA0` defines the base address of the even field; and `DSS.DISPC_GFX_BA1` defines the base of the odd field in the case of an external synchronization and based on the value of the input signal `DISPC_FID` and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (`DSS.DISPC_GFX_FIFO_THRESHOLD` register): The low threshold (`DSS.DISPC_GFX_FIFO_THRESHOLD[11:0]` `GFXFIFOWLOWTHRESHOLD`) and the high threshold (`DSS.DISPC_GFX_FIFO_THRESHOLD[27:16]` `GFXFIFOHIGHTHRESHOLD`) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the `DSS.DISPC_CONFIG[14]` `FIFOMERGE` bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the `DSS.DISPC_GFX_FIFO_THRESHOLD[11:0]` `GFXFIFOWLOWTHRESHOLD` bit field) and the high threshold (`DSS.DISPC_GFX_FIFO_THRESHOLD[27:16]` `GFXFIFOHIGHTHRESHOLD` bit field) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the `DSS.DISPC_CONFIG[14]` `FIFOMERGE` bit reset value is 0).
- Palette/gamma table used (`DSS.DISPC_CONFIG[3]` `PALETTEGAMMATABL` bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (`DSS.DISPC_GFX_TABLE_BA` register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

- Graphics Priority (`DSS.DISPC_GFX_ATTRIBUTES[14]` `GFXARBITRATION`): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (`DSS.DISPC_GFX_ATTRIBUTES[15]` `GFXSELFREFRESH`): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.
The sequence to activate the self-refresh is the following:
 - Frame t: The bit field should be set at anytime during frame
 - Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
 - Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels
The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

7.5.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- [DSS.DISPC_CONFIG](#)
- [DSS.DISPC_GFX_POSITION](#)
- [DSS.DISPC_GFX_SIZE](#)
- [DSS.DISPC_GFX_ATTRIBUTES](#)

The graphics layer is enabled/disabled by setting/resetting the [DSS.DISPC_GFX_ATTRIBUTES\[0\]](#) GFXENABLE bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the [DSS.DISPC_CONTROL\[6\]](#) GODIGITAL or [DSS.DISPC_CONTROL\[5\]](#) GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

7.5.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format ([DSS.DISPC_GFX_ATTRIBUTES\[4:1\]](#) GFXFORMAT bit field): The default value of this bit field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position ([DSS.DISPC_GFX_POSITION\[10:0\]](#) GFXPOSX bit field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position ([DSS.DISPC_GFX_POSITION\[26:16\]](#) GFXPOSY bit field): The default value of this bit field at reset time is 0x0. The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width ([DSS.DISPC_GFX_SIZE\[10:0\]](#) GFXSIZEX bit field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the [DSS.DISPC_GFX_ATTRIBUTES\[7:6\]](#) GFXBURSTSIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the [DSS.DISPC_GFX_ROW_INC](#) register is not 1. When [DSS.DISPC_GFX_ROW_INC](#) register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

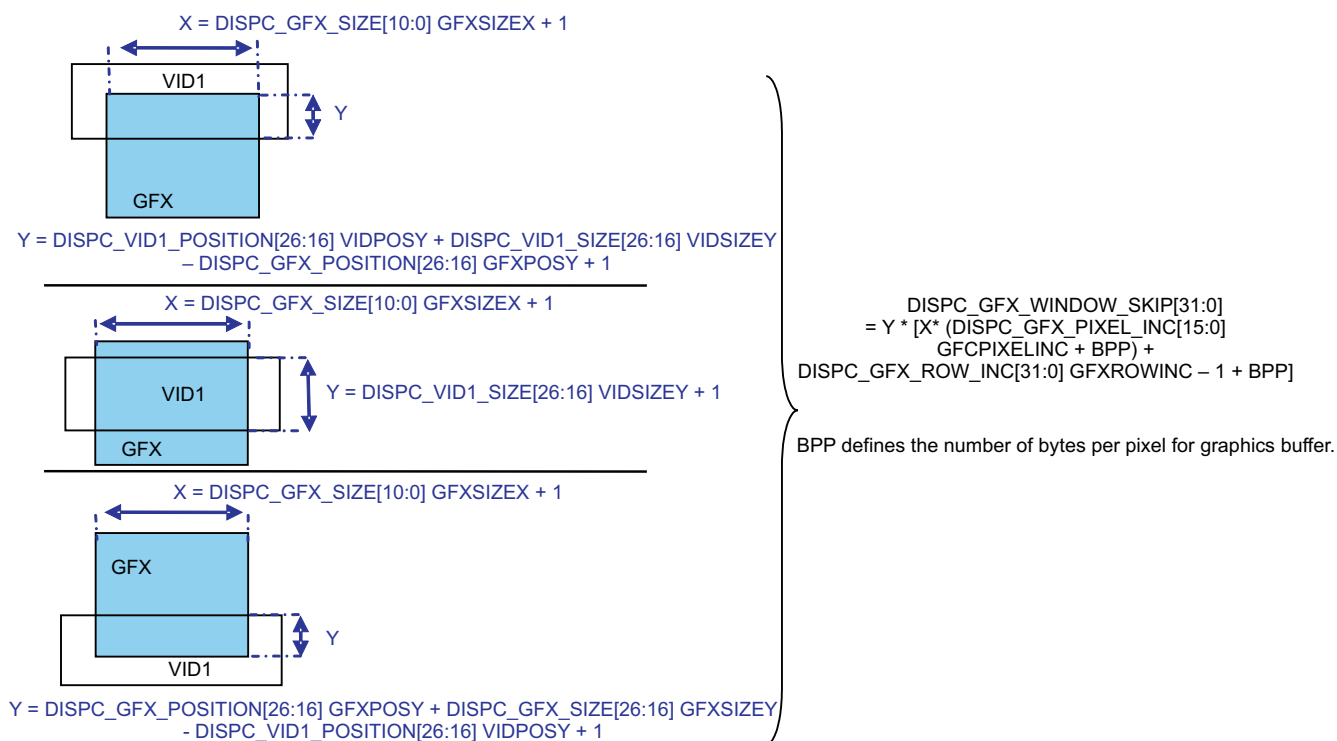

- Graphics window height ([DSS.DISPC_GFX_SIZE\[26:16\]](#) GFXSIZEY bit field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the graphics layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen
- Graphics data endianness ([DSS.DISPC_GFX_ATTRIBUTES\[10\]](#) GFXENDIANNESS bit): This bit indicates the endianness (little or big) of the graphics pixels. The default value at reset time is 0x0 (little endian).
- Graphics data nibble mode ([DSS.DISPC_GFX_ATTRIBUTES\[9\]](#) GFXNIBBLEMODE bit): This bit

indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).

- Graphics replication logic enable (DSS.DISPC_GFX_ATTRIBUTES[5] GFXREPLICATIONENABLE bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the 24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.
- Graphics window skip enable (DSS.DISPC_CONTROL[12] OVERLAYOPTIMIZATION bit): By setting/resetting the bit, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field should be reset. When the color key is used, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field should be reset.
- Graphics window skip (DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

Figure 7-116 through Figure 7-119 give examples of how to program the GFXWINDOWSKIP field for overlay optimization:

7.5.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

7.5.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_VIDn_BAj
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_ROW_INC
- DSS.DISPC_VIDn_PIXEL_INC
- DSS.DISPC_VIDn_FIFO_THRESHOLD
- DSS.DISPC_VIDn_PICTURE_SIZE

The following fields define the attributes of the graphics DMA engine:

- Video layer enable (DSS.DISPC_VIDn_ATTRIBUTES[0] VIDENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size (DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This bit field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_VIDn_ATTRIBUTES[19] VIDFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_VIDn_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_VIDn_ATTRIBUTES[19] VIDFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
 - Active matrix (TFT) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0xB0 (value is 176)
 - Color passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x110 (value is 272)
 - Monochrome passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x1B0 (value is 432)

- Base address of the video buffer in system memory (DSS.DISPC_VIDn_BA_j registers): The default value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register DSS.DISPC_VIDn_BA₀ defines the base address of the even field, and DSS.DISPC_VIDn_BA₁ defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Video FIFO threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD register): The low threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CONFIG[14] FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_VIDn_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) and the high threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CONFIG[14] FIFOMERGE bit reset value is 0).
- Video buffer width (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this bit field to the value minus 1.
- Video buffer height (DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VIDORGSIZEY): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video data endianness (DSS.DISPC_VIDn_ATTRIBUTES[17] VIDENDIANNESS bit, with n=1 or 2): This bit indicates the endianness (little or big) of the video pixels. The default value at reset time is 0x0 (little endian).

7.5.3.3.2 Video Configuration Register

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.DISPC_CONFIG
- DSS.DISPC_VIDn_POSITION
- DSS.DISPC_VIDn_SIZE
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_PICTURE_SIZE
- DSS.DISPC_VIDn_FIR_COEF_H_i (with i = 0 to 7)
- DSS.DISPC_VIDn_FIR_COEF_H_V_i (with i = 0 to 7)
- DSS.DISPC_VIDn_CONV_COEF_i (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[0] VIDENABLE field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

7.5.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT bit field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, nonsupported format by the video pipeline). The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC_VIDn_POSITION[10:0] VIDPOSEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC_VIDn_POSITION[26:16] VIDPOSY bit field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC_VIDn_SIZE[10:0] VIDSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_VIDn_ROW_INC register is not 1. When the DSS.DISPC_VIDn_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Video window height (DSS.DISPC_VIDn_SIZE[26:16] VIDSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.
- Video picture width in system memory (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).
- Video picture height in system memory (the DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VIDORGSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC_VIDn_ATTRIBUTES[23] VIDARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC_VIDn_ATTRIBUTES[24] VIDSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame

- Frame t+1: Fetch of the data from system memory using the L3 interconnect

7.5.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[5] VIDRESIZEENABLE bit.

The video vertical up/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[6] VIDRESIZEENABLE bit.

Set a valid configuration before enabling the video up/downsampling block.

NOTE: Vertical and horizontal downsampling are limited to a 1/4 resize factor.

After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRVINC[12:0] = 1024 \times \left(\frac{VIDORGSIZEY[10:0]}{VIDSIZEY[10:0]} \right) \quad \text{dss-E093} \quad (10)$$

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
 - The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.
-
- Horizontal up/downsampling increment value (DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRHINC[12:0] = 1024 \times \left(\frac{VIDORGSIZEX[10:0]}{VIDSIZEX[10:0]} \right) \quad \text{dss-E094} \quad (11)$$

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
 - The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.
-
- Vertical up/downsampling accumulator value (DSS.DISPC_VIDn_ACCUI[25:16] VIDVERTICALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 7-50](#)).
 - Vertical up/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
 - Vertical up/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus

OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the `DSS.DISPC_VIDn_ATTRIBUTES[22]` `VIDLINEBUFFERSPLIT` bit must be set to 1.

- Vertical up/downsampling line buffer configuration (`DSS.DISPC_VIDn_ATTRIBUTES[20]` `VIDDMAOPTIMIZATION` bit): The default value at reset time is 0x0 (no optimization). If the bit is set, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. If the bit is clear, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV4:2:2) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization. Even width is required for the input picture when the 5-tap configuration is used.

NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

```
DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX 4 and even
```

For more information about the configuration of video DMA optimization, see [Section 7.5.3.4.5, Video DMA Optimization](#).

- Horizontal up/downsampling accumulator value (`DSS.DISPC_VIDn_ACCU[9:0]` `VIDHORIZONTALACCU` bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 7-50](#)).

Table 7-50. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases f
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

- Vertical up/downsampling coefficients (`DSS.DISPC_VIDn_FIR_COEF_HVi` registers, with $n = 1$ or 2 , $i = 0$ to 7): The 3-tap vertical up/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

In addition, there are 2-tap vertical up/downsampling coefficients defined in `DSS.DISPC_VIDn_FIR_COEF_Vi` registers. There are 8 registers for the 8 phases with 2 coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers `DSS.DISPC_VIDn_FIR_COEF_HVi` and `DSS.DISPC_VIDn_FIR_COEF_Vi` are used. In case of 3-tap configuration, only one set of registers `DSS.DISPC_VIDn_FIR_COEF_HVi` is used.

- Horizontal up/downsampling coefficients (`DSS.DISPC_VIDn_FIR_COEF_Hi` and `DISPC_VIDn_FIR_COEF_HVi` registers, with $n = 1$ or 2 , $i = 0$ to 7): The `DSS.DISPC_VIDn_FIR_COEF_Hi` register and the `DSS.DISPC_VIDn_FIR_COEF_HVi` register define the 5-tap horizontal up/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up/downsampling block.

Each `DSS.DISPC_VIDn_FIR_COEF_Hi` register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each `DSS.DISPC_VIDn_FIR_COEF_HVi` register contains one 8-bit signed coefficient.

The programmable coefficient for the FIR up/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see [Section 7.6.1](#).

7.5.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC_VIDn_CONV_COEFi registers (with $i = 0$ to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with $n = 1$ or 2).

The standard register coefficients are:

YCbCr-to-RGB Registers (VidFullRange=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \quad \text{dssE095} \quad (12)$$

YCbCr to RGB Registers (VidFullRange=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix} \quad \text{dss-E096} \quad (13)$$

[Table 7-51](#) lists the color space conversion register values.

Table 7-51. Color Space Conversion Register Values

Coefficients	BT.601-5	BT.601-5 Range [0:255]	BT.709	BT.709 Range [0:255]
RY	298	256	298	256
RCr	409	351	459	394
RCb	0	0	0	0
GY	298	256	298	256
GCr	-208	-179	-137	-118
GCb	-100	-86	-55	-47
BY	298	256	298	256
BCr	0	0	0	0
BCb	517	443	541	465
VidFullRange	0	1	0	1

7.5.3.4 Rotation/Mirroring Display Subsystem Settings

This section describes rotation/mirroring settings. The device provides flexible mechanisms for an efficient implementation of rotation using the display-subsystem, its DMA engine, and the rotation engine of the SMS module. Depending on whether the image data is located in on-chip SRAM or external SDRAM, either a DMA rotation or a VRFB rotation is used. When configuring the rotation, the image data format (RGB or YUV) must also be taken into account. The video pipelines also perform the interpolation of YUV image data and the color conversion from YUV into RGB format for displaying the images on an LCD screen.

7.5.3.4.1 Image Data Formats

To understand the programming of the rotation mechanisms described underneath, the supported representations of the image data in memory must also be considered. Differences exist between the supported formats on the graphics and video pipelines. The graphics pipeline supports RGB and RGB with a color look-up table (CLUT), whereas the video pipelines support two versions of YUV 4:2:2 and RGB16. In the case of YUV, the interpolation and color conversion hardware in the video pipelines converts the image data to the RGB format suitable for the LCD screen.

The graphics pipeline supports:

- 1-, 2-, 4-, and 8-bits-per-pixel color look-up table
- 12-, 16-, and 24-bits-per-pixel RGB

The video pipelines support the following data formats (always 2 bytes/pixel):

- RGB16
- YUV2
- UYVY

For more information on the graphics data formats, please refer to [Section 7.4.2.2, Graphics Pipeline](#).

For more information on the video data formats, please refer to [Section 7.4.2.3, Video Pipeline](#).

In the video pipeline, the YUV 4:2:2 format is converted into a full YUV 4:4:4 format by interpolation of the chrominance values from neighboring pixels. After this interpolation is completed, the conversion to the RGB format (suitable for displaying the image on the LCD screen) is performed.

For more information on YUV 4:2:2 to RGB conversion, please refer to [Section 7.4.2.3.2, Color Space Conversion](#).

7.5.3.4.2 Image Data from On-Chip SRAM

For image data located in the on-chip SRAM, the DSS DMA is used to perform 90-degree, 180-degree, and 270-degree rotation. This is done by using the double-indexed addressing mode of the DMA. This addressing mode allows a pixel and a row increment to be specified. These address increments are used after each pixel or each row (line), respectively. [Figure 7-120](#) illustrates the principle steps for a 90-degree rotation.

Figure 7-120. 90° DMA Rotation Example

dss-097

Table 7-52. 90-degree DMA Rotation Example Description

Parameter	Description	Additional parameters for formulas
ba	Buffer Base Address in Memory	
IW	Image Width in pixels	$iw = IW - 1$
IH	Image Height in pixels	$ih = IH - 1$
ps	Pixel Size (in bytes)	

Figure 7-120 shows how the image is stored in memory and how it is read out to achieve a 90-degree rotated orientation. The first pixel for the 0-degree orientation is located at the buffer base address (ba). If the image is to be shown on an LCD screen with a 90-degree rotation, the readout starts at the 90-degree base address (1). To proceed from one pixel to the next in the same line in the rotated orientation, the pixel increment (2) must be applied. At the end of each line of the rotated view, the row increment (3) is the offset to advance to the beginning of the next line in the memory buffer.

Hence, by setting the three DMA parameters (base address, pixel increment, and row increment), a 90-degree rotation can be achieved, as can 180-degree and 270-degree rotation. Each of the parameters can also be combined with an optional mirroring on the vertical axis.

Following there is a description the setup required to perform the rotation via the DSS DMA. This rotation mechanism is used when the image data is stored in internal SRAM.

7.5.3.4.2.1 Rotation/Mirroring Registers

To set up the rotation and/or mirroring, the following registers must be programmed:

- Graphics pipeline (GFX):
 - DSS.DISPC_GFX_BA_j
 - DSS.DISPC_GFX_PIXEL_INC
 - DSS.DISPC_GFX_ROW_INC
 - DSS.DISPC_GFX_ATTRIBUTES
 - DSS.DISPC_GFX_POSITION
 - DSS.DISPC_GFX_SIZE
 - DSS.DISPC_GFX_FIFO_THRESHOLD
- Video pipelines (VID) 1 and 2:
 - DSS.DISPC_VID_n_BA_j
 - DSS.DISPC_VID_n_PIXEL_INC
 - DSS.DISPC_VID_n_ROW_INC
 - DSS.DISPC_VID_n_ATTRIBUTES
 - DSS.DISPC_VID_n_POSITION
 - DSS.DISPC_VID_n_SIZE
 - DSS.DISPC_VID_n_CONV_COEF0 to DSS.DISPC_VID_n_CONV_COEF4
 - DSS.DISPC_VID_n_FIFO_THRESHOLD
- DSS.DISPC_XXX_BA_j: These registers contain the base address of the image data at which the DSS DMA transfer of the image starts. The register values depend on the rotation chosen (see Table 7-53 for the formulas). When using the LCD interface, the registers DISPC_XXX_BA0 are used. The registers DISPC_XXX_BA1 are only used for the TV output.
- DSS.DISPC_XXX_PIXEL_INC[15:0]: This bit field contains the DMA addressing increment after each pixel. This bit field is used to perform the DSS DMA rotation (see Table 7-53 for the formula).

NOTE: When the RGB24 packet format is selected, the only valid value is 1.

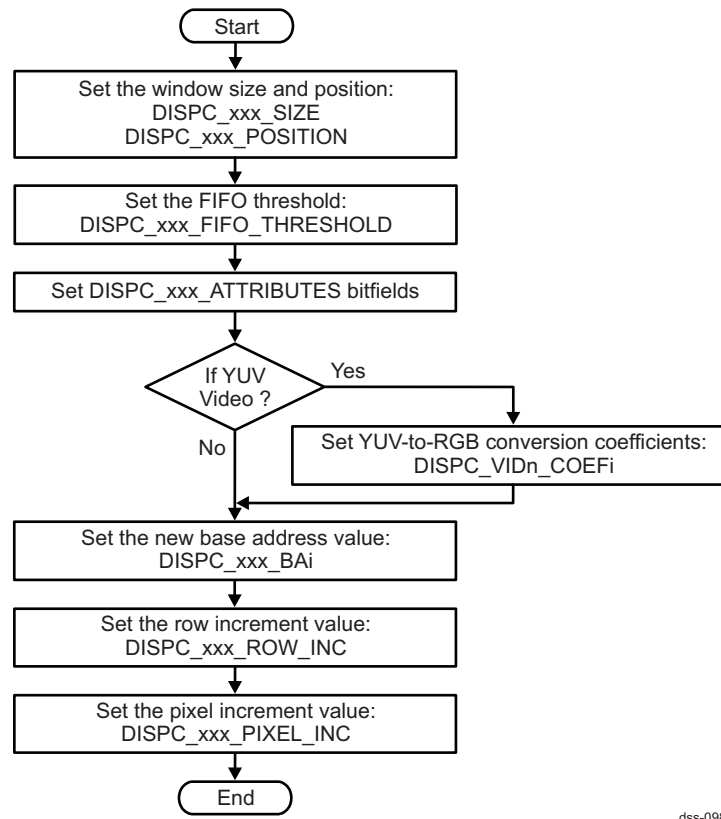

- DSS.DISPC_XXX_ROW_INC[31:0]: This bit field contains the DMA addressing increment after each row (line) of pixels. This bit field is used to perform the DSS DMA rotation (see Table 7-53 for the formula).

NOTE: When the RGB24 packet format is selected, the valid values are 1 and any value multiples of 12 bytes (4x32 bit). When the value is a multiple of 12 bytes, the width must be a multiple of 12 bytes. When the value is 1, the width can be any size from 1 to 2048 pixels.

- DSS.DISPC_xxx_ATTRIBUTES: These registers contain the main settings for the pipeline, such as the image data format, the rotation value, and the enable bit for the pipeline. The bit fields of these registers play a role in the rotation and in the image data format setup.
 - The following bit fields are used by the graphics pipeline to set up the image format:
 - GFXENABLE: Set this field to activate the hardware path in use.
 - GFXFORMAT: Use this field to specify the format of the graphic frame.
 - GFXROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains RGB24 pixel data; otherwise, set it to 0x0 regardless of the degree of rotation.
 - GFXREPLICATIONENABLE: Use this bit to determine whether the encoded pixel data in RGB formats (RGB12 and RGB16) is extended to 24-bit format with or without replication of the MSB to fill the LSBs of each color component. If the replication logic is turned off, the LSB parts are filled with 0s. It is recommended to always enable this feature.
 - GFXCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
 - The following bit fields for the two video pipelines:
 - VIDENABLE: Set this field to activate the hardware path in use.
 - VIDFORMAT: Use this field to specify the format of the video frame (RGB16 or YUV4:2:2).
 - VIDCOLORCONVENABLE: If the video is in YUV4:2:2 format, set this field to enabled.
 - VIDROTATION: Set this field to the value corresponding to the rotation angle desired only if the frame contains non-RGB pixel data; otherwise, set it to 0x0 regardless of the degree of rotation. See [Section 7.5.3.4.4](#) for more information.
 - VIDROWREPEATENABLE: Set this field to enabled only if the frame contains YUV pixel data and the rotation is 90-degree or 270-degree so that the row pixel data are fetched twice to extract both Y components. See [Section 7.5.3.4.4](#) for more information.
 - VIDCHANNELOUT: Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
- DSS.DISPC_xxx_POSITION: Use this register to configure the position of the window.
- DSS.DISPC_xxx_SIZE: Use this register to configure the size of the window.
- DSS.DISPC_VIDn_CONV_COEF0, DSS.DISPC_VIDn_CONV_COEF1, DSS.DISPC_VIDn_CONV_COEF2, DSS.DISPC_VIDn_CONV_COEF3, and DSS.DISPC_VIDn_CONV_COEF4: These registers contain the conversion coefficients required for YUV-to-RGB color conversion.
- DSS.DISPC_xxx_FIFO_THRESHOLD: Set the low threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOWHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values to define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests.

7.5.3.4.2.2 DMA Register Settings

To configure the display controller for rotation and/or mirroring, use the following settings:

Figure 7-121. Rotation/Mirroring Settings

dss-098

NOTE: These registers are shadow registers. To take into account the new values, software users must set the DSS.DISPC_CONTROL[5] GOLCD bit to 1.

Table 7-53 details the base address, the row and pixel increment values to access the buffer in memory (contiguous pixels) except for the RGB24 packet format. Table 7-54 lists the rotation register settings for RGB24 packet format (only for the two video pipelines).

Table 7-53. DMA Rotation Register Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_XXX_BAj DSS.DISPC_XXX_PIXEL_INC DSS.DISPC_XXX_ROW_INC	ba 1 1
90 degrees	DSS.DISPC_XXX_BAj DSS.DISPC_XXX_PIXEL_INC DSS.DISPC_XXX_ROW_INC	ba + (iw x (ih-1) x ps) -(iw x ps) - 1 (iw x (ih-1)) x ps + 1
180 degrees	DSS.DISPC_XXX_BAj DSS.DISPC_XXX_PIXEL_INC DSS.DISPC_XXX_ROW_INC	ba + (iw x ih-1) x ps -2 x ps -2 x ps

(1)

- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See Table 7-52 for more information of these parameters.

Table 7-53. DMA Rotation Register Settings (continued)

Rotation	Registers	GFX/VIDx ⁽¹⁾
270 degrees	DSS.DISPC_xxx_BAj	$ba + (iw - 1) \times ps$
	DSS.DISPC_xxx_PIXEL_INC	$(iw - 1) \times ps + 1$
	DSS.DISPC_xxx_ROW_INC	$-(iw \times (ih - 1)) \times ps - ps + 1$

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

Table 7-54. Video Rotation Register Settings (With RGB24 Packet Format)

Rotation	Registers (with n = 1 or 2)	SDRAM Direct Access ⁽¹⁾
0 degree	DSS.DISPC_VIDn_BAj	ba
	DSS.DISPC_VIDn_PIXEL_INC	1
	DSS.DISPC_VIDn_ROW_INC	1
180 degrees	DSS.DISPC_VIDn_BAj	$ba + (iw * ih * 3) - 4$
	DSS.DISPC_VIDn_PIXEL_INC	-7
	DSS.DISPC_VIDn_ROW_INC	-7

⁽¹⁾

- ba = physical base address of the buffer in the system memory (top-left corner of the picture)
 - iw = number of pixels per row - 1 (original picture in system memory) for BITMAP and RGB formats and number of pixels per row divided by 2 for YUB422 formats
 - h = number of lines - 1 (original picture in system memory)
 - ps = pixel size in bytes (BITMAP8: 1 byte; RGB16: 2 bytes; YUV4:2:2: 4 bytes)
- See [Table 7-52](#) for more information of these parameters.

The DMA rotation described above can be also combined with an optional mirroring on the vertical axis (see [Figure 7-122](#)). The only settings that must be changed to achieve this mirroring are the registers described above: DISPC_xxx_BAj, DISPC_xxx_PIXEL_INC, and DISPC_xxx_ROW_INC. [Table 7-55](#) provides the DMA setup formulas for rotation with mirroring to access the buffer in memory (contiguous pixels) except for the RGB24 packet format.

Figure 7-122. 90° Rotation With Mirroring

Table 7-55. Register Settings for DMA Rotation With Mirroring

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw-1) x ps -2 x ps + 1 2 x (iw-1) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba (iw-1) x ps (-iw x (ih-1)) x ps
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + iw x (ih-1) x ps 1 -2 x iw x ps
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	ba + (iw x ih - 1) x ps (iw - 1) x ps + 1 - (iw x (ih-1)) x ps - ps + 1

(1)

- ba = start address of image buffer in memory
 - iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
 - ih = image height - 1 (number of rows)
 - ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)
- See [Table 7-52](#) for more information of these parameters.

7.5.3.4.3 Image Data From External SRAM

The device offers a rotation engine in the SMS called the VRFB. This rotation method must be used for maximum efficiency when the image data is located in SDRAM. To use the VRFB rotation, both the SMS module and the DSS DMA must be configured.

In the DSS, the same registers must be set up as described for DMA rotation (see [Section 7.5.3.4.2, Image Data from On-Chip SRAM](#)). The differences are in the setup of the following registers:

- DISPC_xxx_ROW_INC: This field contains the DMA addressing increment after each row (line) of pixels. This field is used to add the remaining delta at the end of each line, to reach the 2048-pixel line size of the VRFB (see [Table 7-56](#) for the formula).
- DISPC_xxx_PIXEL_INC: This field contains the DMA addressing increment after each pixel. For VRFB rotation, this value is set always to 1 (see [Table 7-56](#)).

Table 7-56. VRFB Rotation - DMA Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA0 1 (2048 - iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA90 + offset 1 (2048 - ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA180 + offset 1 (2048 - iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA270 + offset 1 (2048 - ih) x ps + 1

(1)

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Figure 7-123 provides the offset values that must be added to the virtual base addresses for 90-degree, 180-degree, and 270-degree rotation. This offset is applicable only when the defined image size in the VRFB module is greater than the actual image size, because it must be a multiple of the page width and height. In the example discussed above, the image height was set to 256 lines, instead of 240, because the page height was 32 lines. This offset must be added to the virtual base addresses, because the VRFB module is not aware of the actual image size. Figure 7-123 illustrates why this occurs and how the offset is calculated.

Figure 7-123. Offset for VRFB Rotation

dss-099

Δiw = Image width delta between the actual image width and the programmed image width because of the page width

Δih = Image height delta between the actual image height and the programmed image height because of the page height:

- Offset 90-degree: Δih pixels = $\Delta ih \times ps$ bytes
- Offset 180-degree: $2048 \times \Delta ih + \Delta iw$ pixels = $2048 \times \Delta ih \times ps + \Delta iw \times ps$ bytes
- Offset 270-degree: $2048 \times \Delta iw$ pixels = $2048 \times \Delta iw \times ps$ bytes

In the example given above, the delta in the image height is $256 - 240 = 16$ lines ($\Delta ih = 16$), whereas the exact value of the width can be programmed ($\Delta iw = 0$). In that case, the resulting offset values are:

- YUV:
 - Offset 90-degree: 16 x 4 bytes
 - Offset 180-degree: 2048 x 16 x 4 bytes
 - Offset 270-degree: 0 bytes
- RGB:
 - Offset 90-degree: 16 x 2 bytes

- Offset 180-degree: 2048 x 16 x 2 bytes
- Offset 270-degree: 0 bytes

As with DMA rotation, mirroring along the vertical axis can be added on top of the rotation when using the VRFB. This mirroring is achieved by combining an appropriate VRFB rotation with a readout of the VRFB by the DSS DMA, going backwards from the last line to the first line of the rotated image. [Table 7-57](#) provides the DMA settings for VRFB rotation with mirroring.

Table 7-57. VRFB Rotation With Mirroring - DMA Settings

Rotation	Registers	GFX/VIDx ⁽¹⁾
0 degree	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA180 + 2048 x (ih - 1) x ps + offset 1 -(2048 + iw) x ps + 1
90 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA270 + 2048 x (iw - 1) x ps + offset 1 -(2048 + ih) x ps + 1
180 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA0 + 2048 x (ih - 1) x ps 1 -(2048 + iw) x ps + 1
270 degrees	DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC	VBA90 + 2048 x (iw - 1) x ps + offset 1 -(2048 + ih) x ps + 1

⁽¹⁾

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Some offsets are required if there is a delta between the programmed image size in the VRFB and the actual image size. As shown in [Figure 7-124](#), this applies to 0-degree rotation with mirroring (using VBA 180-degree), 90-degree rotation with mirroring (VBA 270-degree), and 270-degree rotation with mirroring (VBA 90-degree). The offsets are calculated in this manner:

- Offset 0-degree (mirroring): 2048 x Δih + Δiw pixels = 2048 x Δih x ps + Δiw x ps bytes
- Offset 90-degree (mirroring): 2048 x Δiw pixels = 2048 x Δiw x ps bytes
- Offset 270-degree (mirroring): Δih pixels = Δih x ps bytes

Figure 7-124. Offset for VRFB Rotation With Mirroring

dss-101

7.5.3.4.4 Additional Configuration When Using YUV Format

The rotation flag (DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION bit , with n = 1 or 2) and the repeat flag (DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE) indicate the rotation to apply to the video-encoded pixels from the SDRAM and SRAM. The 2D addressing mode is used, but even when accessing the SDRAM buffer, some post-processing must be performed on the YUV 4:2:2 data depending on the rotation. These bits are set only when the video format is not RGB; otherwise, the bit field is reset to 0. Table 7-58 and Table 7-59 describe the configuration of these registers.

Table 7-58. Video Rotation Register Settings (YUV Only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0

Table 7-58. Video Rotation Register Settings (YUV Only) (continued)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

Table 7-59. Video Rotation With Mirroring Register Settings (YUV only)

Rotation	Registers (with n = 1 or 2)	SDRAM + Rotation engine
0 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x2
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
90 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x1
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1
180 degrees	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x0
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
270 degree	DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION	0x3
	DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE	0x1

NOTE: For YUV4:2:2 video-encoded pixels, the hardware must always fetch a 32-bit value from the system memory to generate a YUV4:4:4 value before YUV-to-RGB conversion.

- For 90- and 270-degree rotation, the missing chrominance samples for the odd pixels are generated by duplicating the chrominance samples of the previous even pixels.
- For 0- and 180-degree rotation, the missing chrominance samples for the odd pixels are generated by averaging the contiguous chrominance samples.

7.5.3.4.5 Video DMA Optimization

When a rotation of 90 or 270 degrees is required, the memory traffic can be reduced as described in [Section 7.4.2.8, Rotation](#).

1. Enable DMA optimization for the video pipelines VID1 and VID2 by applying the following settings to the DISPC:
 - (a) Enable DISPC DMA optimization by setting:
 - DISPC_VIDn_ATTRIBUTES[20] VIDDMAOPTIMIZATION = 1
 - DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE = 0
 - DISPC_VIDn_ATTRIBUTES[13:12] VIDROTATION = 0x1 or 0x3
 - (b) Configure DISPC for the following format:
 - DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT = 0x6, 0xA, or 0xB
 - DISPC_VIDn_ATTRIBUTES[9] VIDCOLORCONVENABLE = 0x1 (only for YUV format)
 - (c) Configure DISPC scaler in 5-tap mode by setting:
 - DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS = 0x1
 - DISPC_VIDn_ATTRIBUTES[6:5] VIDRESIZEENABLE = 0x2 (vertical resize only, minimum setting) or 0x3 (vertical + horizontal resize)
 - DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT = 0x1
2. Configure the rotation engine (VRFB) inside the SDRAM memory scheduler (SMS) as follows:
 - (a) Set the SMS-VRFB context pixel size to 32 bits by setting:
 - For RGB16 pixel format:
 - Writing context: SMS.SMS_ROT_CONTROLn[1:0] PS = 1
 - Reading context: SMS.SMS_ROT_CONTROLn[1:0] PS = 2

- For YUV pixel format:
 - Writing and reading context: SMS.SMS_ROT_CONTROLn[1:0] PS = 2
- (b) Set the SMS-VRFB context width to one half of the original width:
 - SMS.SMS_ROT_SIZE[10:0] IMAGEWIDTH = Picture width in pixels /2 (because 2 pixels are present in each 32-bit container)

For more information about the VRFB module, see [Section 10.2.4.1.5, Rotation Engine](#), in [Section 10.2, SDRAM Controller \(SDRC\) Subsystem](#).

NOTE: When 5-tap mode is used, the scaling coefficients must be set even, if 1:1 scaling is required.

Matrix color space coefficients must be set for YUV format inside [DISPC_VIDn_CONV_COEF0](#) through the [DISPC_VIDn_CONV_COEF4](#) registers.

The width of the input original picture must be even (for YUV4:2:2 and RGB16 formats).

The DMA optimization feature must be used only for YUV and RGB16 formats when 90- or 270-degree rotation is required. In all other configurations, the [DISPC_VIDn_ATTRIBUTES\[20\] VIDDMAOPTIMIZATION](#) bit must be kept at reset value (0x0).

7.5.3.5 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- [DSS.DISPC_CONTROL](#)
- [DSS.DISPC_CONFIG](#)
- [DSS.DISPC_DEFAULT_COLOR_m](#) (m=0)
- [DSS.DISPC_TRANS_COLOR_m](#) (m=0)
- [DSS.DISPC_TIMING_H](#)
- [DSS.DISPC_TIMING_V](#)
- [DSS.DISPC_POL_FREQ](#)
- [DSS.DISPC_DIVISOR](#)
- [DSS.DISPC_SIZE_LCD](#)
- [DSS.DISPC_DATA_CYCLEK](#)
- [DSS.DISPC_CPR_COEF_R](#), [DSS.DISPC_CPR_COEF_G](#), [DSS.DISPC_CPR_COEF_B](#)

Setting/resetting the [DSS.DISPC_CONTROL\[0\] LCDENABLE](#) bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

7.5.3.5.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the [DSS.DISPC_CONTROL\[2\] MONOCOLOR](#) bit)
- Passive Matrix or active Matrix panel (the [DSS.DISPC_CONTROL\[3\] STNTFT](#) bit)
- Color depth (the [DSS.DISPC_CONTROL\[9:8\] TFTDATALINES](#) bit field)
- Number of lines per panel (the [DSS.DISPC_SIZE_LCD\[26:16\] LPP](#) bit field)
- Number of pixels per line (the [DSS.DISPC_SIZE_LCD\[10:0\] PPL](#) bit field)
- 4- or 8-bit interface for Passive Matrix monochrome panel (the [DSS.DISPC_CONTROL\[4\] M8B](#) bit)

7.5.3.5.2 LCD Timings

The following bit fields define the timing generation of HSYNC/VSYNC:

- Horizontal front porch (the [DSS.DISPC_TIMING_H\[19:8\] HFP](#) bit field)

- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- On/Off control of HSYNC/VSNC pixel clock (the DSS.DISPC_POL_FREQ[17] ONOFF bit)
- Program HSYNC/VSNC rise or fall (the DSS.DISPC_POL_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC_POL_FREQ[13] IHS bit)
- Invert VSNC (the DSS.DISPC_POL_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC_CONFIG[6] HSYNCGATED bit)
- VSNC gated (the DSS.DISPC_CONFIG[7] VSYNCGATED bit)

Table 7-60 describes the programming rules for LCD timing.

Table 7-60. Programming Rules

	No Downsampling	Downsampling H or V	Downsampling H + V
$(HBP + HSW + HFP) * PCD$	8	10	20

Figure 7-125 shows the timing values description in the case of an active matrix display.

Figure 7-125. Timing Values Description (Active Matrix Display)

dss-102

The following bit fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC_POL_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC_POL_FREQ[7:0] ACB bit field)
- ac-bias pin transitions per interrupt (DSS.DISPC_POL_FREQ[11:8] ACBI bit field)
- ac-bias gated (DSS.DISPC_CONFIG[8] ACBIASGATED)

The following bit fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC_DIVISOR[7:0] PCD bit field)
- Invert pixel clock (DSS.DISPC_POL_FREQ[14] IPC bit)

- Pixel clock gated (DSS.DISPC_CONFIG[5] PIXELCLOCKGATED bit)

The 8-bit pixel clock divider (the DSS.DISPC_DIVISOR[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

$$\text{Pixel Clock} = (\text{FunctionalClock}/\text{LCD}[7:0])/\text{PCD}[7:0]$$

Table 7-61 through Table 7-64 show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

Table 7-61. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Active Matrix Display

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	2 (1) ⁽¹⁾	2 (1)	2	3	4
	Up	2 (1)	2 (1) ⁽¹⁾	2	3	4
1:1 - 1:2	3-tap	2	2	4	6	8
	5-tap	PCDmin	PCDmin	PCDmin	PCDmin	PCDmin
1:2 - 1:4		PCDmin	PCDmin	PCDmin	PCDmin	PCDmin

⁽¹⁾ The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the pixel clock.

Table 7-62. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono4

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	4	4	8	12	16
	Up	4	4	8	12	16
1:1 - 1:2	3-tap	8	8	16	24	32
	5-tap	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin
1:2 - 1:4		4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin	4xPCDmin

Table 7-63. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Mono8

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	8	8	16	24	32
	Up	8	8	16	24	32
1:1 - 1:2	3-tap	16	16	32	48	64
	5-tap	8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin
1:2 - 1:4		8xPCDmin	8xPCDmin	4xPCDmin	8xPCDmin	8xPCDmin

Table 7-64. Pixel Clock Frequency Limitations - RGB16 and YUV4:2:2 Passive Matrix Display - Color

Min PCD Values		Horizontal Resampling				
		Off	Up	1:1 - 1:2	1:2 - 1:3	1:3 - 1:4
Vertical Resampling	Off	3	3	6	9	12
	Up	3	3	6	9	12
1:1 - 1:2	3-tap	6	6	12	18	24
	5-tap	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin
1:2 - 1:4		3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin	3xPCDmin

NOTE: In case of RGB24 format, [Figure 7-126](#) is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

Figure 7-126. PCDmin Formulas (V Down-Sampling Only)

$$h_ratio = \frac{DISPC_SIZE_LCD[10:0]PLL}{DISPC_VIDn_SIZE[10:0]VIDZSIZE}$$

$$v_ratio = \frac{DISPC_VIDn_PICTURE_SIZE[10:0]VIDORGSIZE}{DISPC_VIDn_SIZE[10:0]VIDSIZE}$$

$$PCDmin = \frac{v_ratio}{2 \times h_ratio} \quad 1 < v_ratio \leq 2$$

$$PCDmin = \max\left(\frac{v_ratio}{2 \times h_ratio}, \frac{v_ratio - 2}{2 \times (h_ratio - 1)}\right) \quad 2 < v_ratio \leq 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by n , $PCDmin = n$

For H+V downsampling, the formula is the following:

$PCDmin = \max(PCDmin\ H\ only, PCDmin\ V\ only)$ as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.DISPC_TIMING_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- Number of lines per panel (the DSS.DISPC_SIZE_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_LCD[10:0] PPL bit field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.DISPC_CONTROL[4] M8B bit)

The following bit fields define the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
- Spatial/temporal dithering logic number of frames (DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERFRAMES bit field). The default value of this bit field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this bit field value while the spatial/temporal unit is enabled.

The following bit field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.DISPC_CONFIG[0] PIXELGATED bit).

7.5.3.5.3 LCD Overlay

The following bit fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR0i register ($i = 0$))
- Transparency color key enable (the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit)

- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR bit field (i=0).
- Alpha blender Enable (DSS.DISPC_CONFIG[18] LCDALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When all of these fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

7.5.3.5.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.DISPC_DATA_CYCLEk (k=0) register)
- Second cycle (the DSS.DISPC_DATA_CYCLEk (k=1) register)
- Third cycle (the DSS.DISPC_DATA_CYCLEk (k=2) register)
- Enable (the DSS.DISPC_CONTROL[20] TDMENABLE bit)
- Parallel mode (the DSS.DISPC_CONTROL[22:21] TDMPARALLEMODE field)
- Cycle format (the DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT field)
- Unused bits (the DSS.DISPC_CONTROL[26:25] TDMUNUSEDBITS field)

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

7.5.3.5.5 LCD Spatial/Temporal Dithering

The following bit fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field) with:
 - 0x0 Spatial only (default value)
 - 0x1 Spatial + Temporal over two frames
 - 0x2 Spatial + Temporal over four frames
 - 0x3 Reserved
- Enable (the DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

7.5.3.5.6 LCD Color Phase Rotation

The following bit fields define the color phase rotation configuration:

- Enable (the DSS.DISPC_CONFIG[15] CPR bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_R register)
- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, and DSS.DISPC_CPR_COEF_B, as described in Figure 7-127 through Figure 7-130.

Figure 7-127. Color Phase Rotation Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{pmatrix} \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix} \end{pmatrix}$$

dss-E105

Figure 7-128. Color Phase Rotation Matrix (R Component Only)

$$R_{iout} = \frac{1}{256} * (RR * R_{in} + RG * G_{in} + RB * B_{in})$$

dss-E106

Figure 7-129. Color Phase Rotation Matrix (G Component Only)

$$G_{out} = \frac{1}{256} * (GR * R_{in} + GG * G_{in} + GB * B_{in})$$

dss-E107

Figure 7-130. Color Phase Rotation Matrix (B Component Only)

$$B_{out} = \frac{1}{256} * (BR * R_{in} + BG * G_{in} + BB * B_{in})$$

dss-E104

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

7.5.3.5.6.1 Color Phase Rotation - Diagonal Matrix

The Color Phase Rotation feature is useful when using an LCD backlight that is not white. By using a correct configuration of the R, G and B coefficients of CPR, the color bias of the screen can be corrected. The following paragraphs give an example of configuration of the CPR feature.

The easiest example of CPR configuration is a diagonal matrix. This way, the output colors depends on one input color only. [Figure 7-131](#) gives the example of a diagonal matrix and the corresponding equation of the output components.

Figure 7-131. Diagonal Matrix Configuration

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & 0 & 0 \\ 0 & GG & 0 \\ 0 & 0 & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (RR * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (GG * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (BB * B_{in})$$

dss-200

According to these 3 new equations, each output component only depends on the corresponding input color. The coefficients can easily be used to reduce the impact of a non-white backlight.

Let's take the example of a "blue" backlight. In this case, users have the feeling that a blue film has been added on the screen, and then each color seems to be "too much blue". The goal is then to reduce the "Blue" component and to keep the "Red" and "Green" ones unchanged. The following matrix can be used for a reduction by a half of the blue component. [Figure 7-132](#) gives the corresponding matrix and equations for each component.

Figure 7-132. Example - Diagonal Matrix Configuration

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ 0 & 0 & 128 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in}) \Rightarrow R_{out} = R_{in}$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in}) \Rightarrow G_{out} = G_{in}$$

$$\rightarrow B_{out} = \frac{1}{256} * (128 * B_{in}) \Rightarrow B_{out} = 0.5 * B_{in}$$

dss-201

[Figure 7-133](#) shows the result of an image on a "blue" backlight screen with and without CPR.

Figure 7-133. Image With and Without CPR (Diagonal Matrix)

dss-202

A drawback of this diagonal matrix is that the color reduction is linear. The contrast is then different from the initial image. It is then necessary to use the 6 other coefficients of the CPR matrix to better correct a non-white backlight. The goal is to find the correct coefficients that remove the color offset added by the non-white backlight.

7.5.3.5.6.2 Color Phase Rotation - Standard Matrix

In the following example, the LCD backlight adds an offset of 128 (B_{offset}) to the Blue component. [Figure 7-134](#) shows an example of matrix that reduces the offset of the screen, the corresponding equations and the resulting output colors.

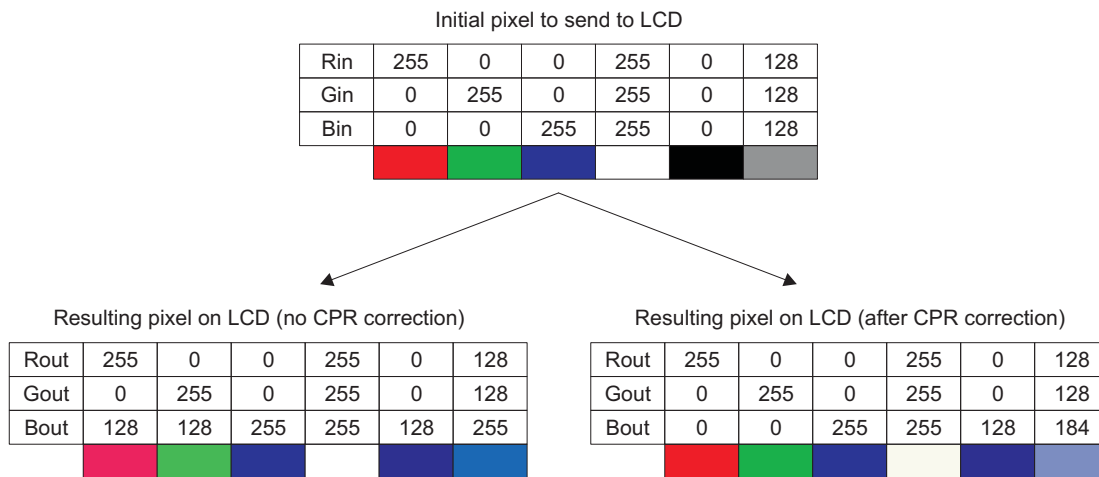

Figure 7-134. Example - Image With and Without CPR (Standard Matrix)

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ -129 & -129 & 370 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (-129 * R_{in} + -129 * G_{in} + 370 * B_{in}) + B_{offset}$$

dss-203

This CPR matrix gives inputs and outputs very close. However, black cannot be corrected because of its zero-components. No matter which coefficients are used in the matrix, the result will always be equal to the offset added by the LCD backlight.

7.5.3.6 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_CONFIG
- DSS.DISPC_DEFAULT_COLOR_m (m=1)
- DSS.DISPC_TRANS_COLOR_m (m=1)
- DSS.DISPC_SIZE_DIG

The digital output is enabled/disabled by setting/resetting the DSS.DISPC_CONTROL[1] DIGITALENABLE bit. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
5. Enable the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQENABLE[15]

SYNCLOSTDIGITAL bit to 1.

7.5.3.6.1 Digital Timings

The following bit fields define the timing information:

- Data hold time (the DSS.DISPC_CONTROL[19:17] HT bit field)
- Logic clock divisor (the DSS.DISPC_DIVISOR[23:16] LCD bit field)

The 8-bit pixel clock divider (DSS.DISPC_DIVISOR[23:16]) bit field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

7.5.3.6.2 Digital Frame/Field Size

The following bit fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC_SIZE_DIG[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_DIG[10:0] PPL bit field)

7.5.3.6.3 Digital Overlay

The following bit fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR_m register (m=1))
- Transparency color key enable (the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR bit field (i=1).
- Alpha blender Enable (DSS.DISPC_CONFIG[19] TVALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When this bit field is set to the appropriate values, set the DSS.DISPC_CONTROL[6] GODIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC_CONTROL[1] DIGITALENABLE bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[1] DIGITALENABLE bit will be set to 1.

7.5.4 DSI Protocol Engine Basic Programming Model

This section describes the programming model of the DSI protocol engine.

7.5.4.1 Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSS.DSI_SYSCONFIG[1] SOFT_RESET bit to 1. The software can monitor the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit to wait for the completion of the reset procedure. If after 5 reads, the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

NOTE: This software reset is optional as a hardware reset is always performed on the DSI protocol engine at device reset.

7.5.4.2 Power Management

The power management behavior of the DSI protocol engine is controlled by the DSS.DSI_SYSCONFIG register. This register completely controls the way the module interferes with the PRCM module. The DSS.DSI_SYSCONFIG[0] AUTO_IDLE bit should be set to 1 (default value) to enable automatic clock gating in the module.

7.5.4.3 Interrupts

There is a single interrupt request: DSI_IRQ. This interrupt line is merged with another interrupt line from the DISPC_IRQ in a single interrupt request DSS_IRQ. The DSI_IRQ events are generated only for the enabled VC(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSS.DSI_IRQENABLE register: This register indicates the enabled/disabled event for the VCs. Each event for the VC is configured in the DSS.DSI_VCn_IRQENABLE register dedicated to the VC number. In addition, it includes one bit for the enable of error reporting for the complex I/O: Error signaling from the complex I/O: The interrupt is triggered when any error is received from the complex I/O (ErrSyncEsc[4:0], ErrEsc[4:0] (edge trigger interrupt), ErrControl[4:0] and ErrContentionLP0[4:0], ErrContentionLP1[4:0] from the complex I/O).
- DSS.DSI_IRQSTATUS register : The register DSI_IRQSTATUS flags which VC(s) is/have generated an interrupt. Based on the VC number, the register DSI_VCn_IRQSTATUS indicates the event generating the interrupt. In addition, it includes one bit for the status of error reporting for the complex I/O.

7.5.4.4 Global Register Controls

Prior to receive data from the DSI complex I/O, the DSI_PHY_SCP registers in the DSI complex I/O must be configured. Refer to [Section 7.5.6](#) for more details. [Table 7-65](#) details the register access width limitations for all the DSI modules.

Table 7-65. Register Access Width Limitations

Register Name	Register Access Width
All DSI complex I/O register (DSI_PHY_SCP)	32-bit only
All DSI PLL control module registers	32-bit only
DSI_VCn_LONG_PACKET_HEADER	32-bit only
DSI_VCn_SHORT_PACKET_HEADER	32-bit only
DSI_VCn_LONG_PACKET_PAYLOAD	16-bit, 32-bit
All others DSI protocol engine registers	8-bit, 16-bit and 32-bit

CAUTION

In case of different access width detailed in [Table 7-65](#), an OCP error is generated in response to the write using SResp=ERR.

The DSI protocol engine is globally controlled by the DSS.DSI_CTRL register. The interface to the complex I/O is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSS.DSI_CTRL[0] IF_EN bit is set to 1, the pending packets should be sent to the DSI complex I/O, the data transfer from the video port should be ignored only when received the next Vertical Sync Event which is received but not send to the DSI complex I/O.

When the DSS.DSI_CTRL[0] IF_EN bit is reset by software, the hardware should finish the transfer of the pending data in the TX FIFO and wait for response if BTA has been sent (Protocol engine is receive mode), then the hardware resets the DSS.DSI_CTRL[0] IF_EN bit. When using the video mode, the VC associated with the video port should be enabled prior to enable the interface according to the following sequence:

- DSS.DSI_CTRL[0] IF_EN bit is equal to 0
- Enable the VC associated with video mode by setting the DSS.DSI_VCn_CTRL[0] VC_EN
- Set the DSS.DSI_CTRL[0] IF_EN bit to 1

7.5.4.5 Virtual Channels

There is one set of registers for each VC. The attributes of the VC define the following characteristics:

- Transfer mode (DSS.DSI_VCn_CTRL[4] MODE bit):
 - Video mode
 - Command mode
- Data type
- Source (DSS.DSI_VCn_CTRL[1] SOURCE bit)
 - Video port
 - L4 interconnect port
- HS or LP forward transmission
- Automatic bus turn-around generation
 - Short packets (DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN bit)
 - Long packets (DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bit)
- DMA request configurations for RX and TX
 - DMA request number (DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB bit field for RX FIFO and DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field for TX FIFO)
 - DMA threshold (DSS.DSI_VCn_CTRL[26:24] DMA_RX_THRESHOLD bit field for RX FIFO and DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field for TX FIFO)
- Mode speed (DSS.DSI_VCn_CTRL[9] MODE_SPEED bit)
- ECC transmission (DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit)
- CS transmission (DSS.DSI_VCn_CTRL[7] CS_TX_EN bit)

The VC ID not calculated by the DSI module but provided while writing into the registers [DSI_VCn_SHORT_PACKET_HEADER](#) and [DSI_VCn_LONG_PACKET_HEADER](#).

7.5.4.6 Packets

The DSS.DSI_VCn_SHORT_PACKET_HEADER register is used to send only short packets (ECC can be calculated by hardware or by software user for debug purpose). The register is not used for video mode data since the short packets are generated by the hardware using the following information:

- synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)
- DSS.DSI_CTRL[18] VP_HSYNC_END
- DSS.DSI_CTRL[17] VP_HSYNC_START
- DSS.DSI_CTRL[16] VP_VSYNC_END
- DSS.DSI_CTRL[15] VP_VSYNC_START

- DSS.DSI_CTRL[10] VP_HSYNC_POL
- DSS.DSI_CTRL[11] VP_VSYNC_POL
- DSS.DSI_VCn_CTRL[1] SOURCE

The DSS.DSI_VCn_LONG_PACKET_HEADER register is used to provide header for long packets (ECC is always calculated by hardware). The register is used for video mode and command mode. If the video mode is enabled for the VC, it is not possible to transfer concurrently (interleaved in a frame) data using long packets received on the video port and on the L4 interconnect port since the DSS.DSI_VCn_LONG_PACKET_HEADER register is used by the video mode. The register can be unprogrammed by users to send long packets received on the L4 interconnect port only when software users know that there is no expected data on the video port. The software should correctly program the register to send sequentially long packets in video and command modes.

The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide payload data for long packets (Check-sum is calculated by hardware when DSS.DSI_VCn_CTRL[7] CS_TX_EN is set to 1 otherwise the value 0x00 is used). The register is not used in video mode since payload data are provided by the video port. The software should ensure that the following sequence for write accesses to the header and payload registers (DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD, respectively) is followed:

- A long packet header value with WC=0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register can be followed by any access.
- A long packet header value with WC0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register should be followed by one or more writes to the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register defined by the WC value before writing again to the same DSS.DSI_VCn_LONG_PACKET_HEADER register.

CAUTION

If this sequence is not followed, no error is generated. The access to other DSI registers during this sequence is allowed.

7.5.4.7 DSI Complex I/O

Prior to send/receive any data from the complex I/O, the DSI complex I/O timings should be set according to the display module timings. The DSI complex I/O pads must also be configured first. See [Section 7.5.6, DSI Complex I/O Basic Programming Model](#).

7.5.4.8 Video Mode

The DSS.DSI_VM_TIMING1, DSS.DSI_VM_TIMING2, DSS.DSI_VM_TIMING3, DSS.DSI_VM_TIMING4, DSS.DSI_VM_TIMING5, DSS.DSI_VM_TIMING6, and DSS.DSI_VM_TIMING7 registers define the timings of the video mode.

The DSS.DSI_CTRL[20] BLANKING_MODE bit defines if the long blanking packets or LPS state are used during the blanking periods (except HFP, HBP, HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. The software should ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSS.DSI_VCn_CTRL[9] MODE_SPEED bit is set to 1 (High-Speed mode) to keep the video mode transfer is HS mode during blanking periods (except for the last blanking period since it is required to go LPS at least once per frame).

The DSS.DSI_CTRL[21] HFP_BLANKING_MODE, DSS.DSI_CTRL[22] HBP_BLANKING_MODE and DSS.DSI_CTRL[23] HSA_BLANKING_MODE define if these blanking can send packets from the TX FIFO or should be kept in HS mode using only long blanking packets.

To ensure that the writes to the register DSS.DSI_VCn_LONG_PACKET_HEADER are correctly handled as header information for video mode long packets, the following registers should be programmed:

- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1
- DSS.DSI_VCn_CTRL[4] MODE bit set to 1
- DSS.DSI_VCn_LONG_PACKET_HEADER register access

- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1

NOTE: The DSS.DSI_VCn_CTRL[1] SOURCE and DSS.DSI_VCn_CTRL[9] MODE_SPEED bits are ignored by hardware when the video mode is selected (DSS.DSI_VCn_CTRL[4] MODE bit set to 1)

The interrupt events SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ indicates if the DSI protocol engine has not been able to resynchronize the video port timing to its own timing base or if it has been done. The RESYNCHRONIZATION_IRQ indicates software users that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI Protocol engine may need to be modified to avoid the resynchronization to occur. The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ events can be respectively monitored in DSS.DSI_IRQSTATUS[18] SYNC_LOST_IRQ and DSS.DSI_IRQSTATUS[5] RESYNCHRONIZATION_IRQ status bits.

The DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

7.5.4.9 Video Port Data Bus

The DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field is used to determine the width of the data bus on the video port. The supported formats are 16-bit, 18-bit and 24-bits.

7.5.4.10 Command Mode

7.5.4.10.1 Command Mode TX FIFO

The single TX FIFO is used on the L4 interconnect port to receive the data to be sent to the peripheral. The configuration of the FIFO for a specific VC should be done only when the VC is disabled.

Users should not enable the VC if there is still some pending data in the TX FIFO for the corresponding space allocated for the VC from previous active period. When the VC space in the TX FIFO is empty, the VC can be enabled.

For each VC, two dedicated DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used to provide data for long packets. The register DSS.DSI_VCn_SHORT_PACKET_HEADER is used to provide data for short packets (32-bit long).

For each long packet, the DSS.DSI_VCn_LONG_PACKET_HEADER register should be written first and then the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The only exception is when the word count defined in the header is equal to 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header should be written into the DSS.DSI_VCn_LONG_PACKET_HEADER register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the VC capability.

The 32-bit write requests only for each VC to the TX FIFO should be kept in order while sending the data to the DSI_PHY inside the VC requests. The only exception is in the case of last 32-bit write for the last bytes of the payload data since it could be 1, 2, 3, or 4 bytes.

Also in case the last transfer is a 32-bit write but the number of valid bytes is 1, 2, or 3 only (calculated using the header word count and the number of bytes are received for the payload), the hardware should store the 32-bit value into the TX FIFO but the invalid bytes are not sent, and are discarded.

When the word count defined in DSS.DSI_VCn_LONG_PACKET_HEADER register is not a multiple of the request threshold value defined in DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field, 32-bit requests and/or bytes should be discarded by the hardware to store in FIFO only the exact number of valid bytes.

The DSI protocol module should be able to determine if the bytes in the TX FIFO correspond to a short or long packet without decoder the DT field. When the bytes are written into the [DSS.DSI_VCn_SHORT_PACKET_HEADER](#), [DSS.DSI_VCn_LONG_PACKET_HEADER](#), and [DSS.DSI_VCn_LONG_PACKET_PAYLOAD](#) registers, the hardware should store the information concerning long or short packet. A 1-bit flag should be used for each entry of the TX FIFO.

When the VC is disabled, the remaining bytes in the FIFO should be sent to the DSI link. The start event to send data to the DSI link one of the following events:

- All bytes have been received in the FIFO (header + payload).
- The space of the FIFO allocated for the VC is full.
- The space of the FIFO allocated for the VC is not enough to request more data using DMA request (threshold value bigger than space left in the TX FIFO for the VC).

NOTE: In case the video mode is active, the blanking period should be large enough to allow the transfer of the packet(s).

Sequential arbitration must be set (TX_FIFO_ARBITRATION[3] [DSI_CTRL](#) bit = 0x1) if only one VC is used to send multiple packets during the same blanking period.

When consecutive packets should be sent in HS mode, to ensure that there is no LP transition between them at least one of the following condition should be valid:

- Packets from the same VC
- Short packets or long packets with a payload size multiple of 4 bytes

To flush the FIFO (discard of the data) for some pending bytes, the software should change the allocated size of the chunk FIFO by:

- First disabling the VC resetting [DSS.DSI_VCn_CTRL\[0\]](#) VC_EN bit to 0
- Second change the size of the space of FIFO to 0 by writing the [DSS.DSI_TX_FIFO_VC_SIZE](#) VCn_FIFO_SIZE (n is the VC value between 0 and 3)

If there is an on-going packet transfer from the TX FIFO to DSI_PHY, the flush of the FIFO should stop immediately the transfer. Because the FIFO is accessible to users, it must ensure that there are no bytes left in the FIFO before starting the flush operation. But it can be required in dead-lock situation to flush the FIFO even if there are still bytes in the FIFO, in that case, the software should also take care of having a known state of the whole DSI protocol engine module (software reset may be required) To start of new transfer through the TX FIFO.

Users can check that there is no pending request before changing the size of the allocated FIFO for the VC by reading the relevant [DSS.DSI_VCn_CTRL\[15\]](#) VC_BUSY bit or by using the interrupt [PACKET_SENT_IRQ](#): All the packets have been sent by counting the transferred requests to the L4 interconnect port and the number of requests sent to the DSI complex I/O. This interrupt can be monitoring by reading the [DSS.DSI_VCn_IRQSTATUS\[2\]](#) [PACKET_SENT_IRQ](#) status bit.

The [DSS.DSI_CTRL\[3\]](#) TX_FIFO_ARBITRATION bit defines if the arbitration scheme is:

- Round-robin between enabled VCs with pending ready requests (pending ready request means that all bytes for the packets are in the FIFO or the space of the FIFO for the VC is full) starting from the VC which has the least VC ID number.
- Sequential: All the pending ready requests for one VC are sent before moving to another VC. The condition of "space of the FIFO is full" should be evaluated after the end of each packet.

If users want to use sequential arbitration for all requests for all channels, a single VC should be used. (the VC ID defined in the header provided to the hardware using either the [DSS.DSI_VCn_LONG_PACKET_HEADER](#) or [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) register is not used and not modified by the DSI protocol engine).

The register `DSS.DSI_TX_FIFO_VC_SIZE` defines the allocated number of 33-bit values for each VC in the TX FIFO and the start address for each VC. The size of the space allocated in the TX FIFO defined by `DSS.DSI_TX_FIFO_VC_SIZE.VCn_FIFO_SIZE` (n corresponds to the VC number n) bit fields should be a multiple of the threshold defined in `DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD` bit field. Only the enabled VCs should be taken into account. To change the size of the space of the memory allocated for a specific VC, the VC should be disabled by setting the `DSS.DSI_VCn_CTRL[0] VC_EN` bit to 0. The whole FIFO may not be used by all the VCs at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

Table 7-66 indicates the corresponding values for the size of the space allocated in the FIFO.

Table 7-66. Virtual Channel TX FIFO Size Values

<code>DSI_TX_FIFO_VC_SIZE.VCn_FIFO_SIZE[n = 0, 3]</code>	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of TX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

Table 7-67 indicates the start address of the space in the FIFO.

Table 7-67. Virtual Channel TX FIFO Start Address

<code>DSI_TX_FIFO_VC_SIZE.VCn_FIFO_ADD[x = 0, 2]</code>	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

There must be no overlap of different VCs spaces.

When the TX FIFO is full:

- the overflow interrupt (`FIFO_TX_OVF_IRQ`) is generated. To monitor this interrupt request, users can read the `DSS.DSI_VCn_IRQSTATUS[3] FIFO_TX_OVF_IRQ` status bit.
- there is no L4 interconnect error generated
- the commands are accepted but the data are not written into the FIFO

To ensure that all writes are correctly stored in the TX FIFO, the FIFO should not be full. The software must read the room in the space allocated for the VC in the TX FIFO by reading the `DSS.DSI_TX_FIFO_VC_EMPTYNESS` register. In case there is no space allocated in the TX FIFO for the VC, the `DSS.DSI_TX_FIFO_VC_EMPTYNESS` register indicates a value of 0 for the VC space emptiness.

When waiting to receive the first VSYNC event on the video port to start the video mode on DSI link no command data from TX FIFO should be sent on the interface. It is required to ensure that when receiving the VSYNC event, there is no on-going command mode transfer that could delay the start of video mode on the DSI link.

7.5.4.10.2 Command Mode RX FIFO

The RX FIFO is used to store the data received from the DSI complex I/O. The data are always packed in the RX FIFO (single or multiple packets receiving during a single or multiple BTA periods).

The read requests access to corresponding VC locations to transfer data for a specific VC. The logic managing the FIFO must be able to extract 32-bit values in-order for a specific VC upon read requests. The byte enable of the read access is ignored. Each read returns one 32-bit value from the RX FIFO. If the application accesses the RX FIFO should extract always 32-bit values. Only in the case of 1, 2, or 3 bytes are remaining in the RX FIFO.

The read requests (single or burst) can be less, equal or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transfer. In that case, the logic should keep the VC information to provide the rest of the data during the next read request(s).

The register `DSS.DSI_RX_FIFO_VC_SIZE` defines the allocated number of 33-bit values for each VC in the RX FIFO and the start address for each VC. Only the enabled VCs should be taken into account. to change the size of the space of the memory allocated for a specific VC, the VC should be disabled by resetting the `DSS.DSI_VCn_CTRL[0]` `VC_EN` bit to 0. The whole FIFO may not be used by the entire VC at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

Table 7-68 indicates the corresponding values for the size of the space allocated in the FIFO:

Table 7-68. Virtual Channel RX FIFO Size Values

<code>DSI_RX_FIFO_VC_SIZE.VCx_FIFO_SIZE[x = 0, 3]</code>	Space Size (up to the size of the FIFO)
0	0 x 33 bits
1	32 x 33 bits
2	64 x 33 bits
3	96 x 33 bits
4	128 x 33 bits

The total size of RX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

Table 7-69 indicates the start address of the space in the FIFO.

Table 7-69. Virtual Channel RX FIFO Start Address

<code>DSI_RX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]</code>	Start Address
0	0
1	32
2	64
3	96
4	128

CAUTION

There must be no overlap of different VCs spaces.

While reading the received bytes in the RX FIFO, only the `DSS.DSI_VCn_SHORT_PACKET_HEADER` register is used since the hardware does not keep track of the header position for long packets and start/end of each packet. The software must extract the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The `DSS.DSI_VCn_LONG_PACKET_HEADER` and `DSS.DSI_VCn_LONG_PACKET_PAYLOAD` registers are not used.

The ECC is only used by the first header when receiving multiple packets during the same LP RX transfer from the peripheral since the DSI Protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the Check-sum does not be enabled since the hardware checks the check-sum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, the hardware does not detect any header and cannot check or/and detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- there is no OCP error generated
- the commands are accepted and the data for the responses are 0s

7.5.4.10.3 Command Mode DMA Requests

The DMA requests (DSI_DMA_REQ) are used to allow automatic transfer by the system DMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure. The DSI protocol engine should access each write request in a burst without any IDLE between. For read OCP request in a burst to RX FIFO, the acceptance is sent immediately and the response is delayed by at least four L4 interface clock (DSS_L4_ICLK) cycles. In case of register reads, the response is returned in the first clock cycle.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable by software. Users program the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD and DSS.DSI_VCn_CTRL[26:24] DMA_RX_THRESHOLD bit fields for TX FIFO and RX FIFO, respectively. Hardware asserts the DMA request based on the threshold value. The size of the space allocated in TX FIFO for each VC must be a multiple of the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field value.

The only exception is in the case of the RX FIFO when the LP data transfer finishes and the threshold value is not reached. In that case the DMA request must be asserted. Therefore, the drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

In case of TX FIFO, if all the bytes defined by the word count field in the DSS.DSI_VCn_LONG_PACKET_HEADER header register have been received, the DMA request is no longer asserted even during the last transfer less than DMA_TX_THRESHOLD number of bytes have been received because of the word count being not a multiple of the DMA_TX_THRESHOLD value.

In case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the system DMA must be programmed to read the number of received bytes in the FIFO. If users do not know the size of the received bytes, the direct access of the RX FIFO through the DSS.DSI_VCn_SHORT_PACKET_HEADER register is performed until the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY bit goes to 0.

The use of each DMA request is programmable by software. The DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB is dedicated to DMA request numbering for the TX FIFO. The DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO or BTA has been received from peripheral indicating end of the transfer from peripheral to host for a transfer to the system memory, the DMA request corresponding to the VC ID is generated.

The system DMA transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (user should know the number of expected received bytes to program correctly the system DMA). When the system DMA transfers a multiple number of threshold value, the DSI protocol engine should send 0s for the data when there is no more received data in the RX FIFO for the VC. Software users must parse the data and determine the valid bytes.

Software users can decide to determine the number of data received in the RX FIFO to read the information in the DSS.DSI_RX_FIFO_VC_FULLNESS register. Then the system DMA can be programmed to read the number of bytes from the RX FIFO. The BTA interrupt (BTA_IRQ) must be used to know when to read the number of received bytes. To monitor the BTA interrupt, the user must read the DSS.DSI_VCn_IRQSTATUS[5] BTA_IRQ status bit. The DMA request must not be selected until the system DMA is programmed with the correct number of data to read from RX FIFO.

If the RX FIFO space for the VC is expected to be overflow because the number of data to be received is greater than the space allocated for the VC, the previous programming model must be used. In place, the DMA request must be asserted as soon as the threshold is reached or when BTA is received.

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the VC ID is generated.

NOTE: To obtain best efficiency of the transfer the size of the request (read or write, single or burst) must be aligned with the threshold value.

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same VC ID or different VC IDs.

7.5.4.11 Ultra-Low Power State

This section describes how to enter/exit to/from ultralow-power state (ULPS).

NOTE: The DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIGy bits (x range is 1 to 3 corresponding to lane #1 to lane #3, and y range is 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This is to take latency at low TxClkEsc frequencies into account.

7.5.4.11.1 Entering ULPS

To enter into ULPS for a clock lane, the following sequence is required:

1. Wait for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY and DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bits to be reset to 0 and ensure that the DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is 0.
2. TxUlpsClk state changes from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

To enter into ULPS for a data lane, the following sequence is required:

1. Wait for all TX_FIFOs for all VCs working in HS are empty, for video mode is not active, and for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY bit is reset to 0 (in addition for data lane #1, DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bit is reset to 0)
2. TxRequestEsc state changes from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2.LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

7.5.4.11.2 Exiting ULPS

To exit from ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane

#3) bit to 0.

6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a clock lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO to OFF state by setting DSS.DSI_COMPLEXIO_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit for clock lane to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the application wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxRequestEsc signals to INACTIVE state for the data lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO into OFF state by setting DSS.DSI_COMPLEXIO_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxRequestEsc signals to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

When the sequence for entering/exiting into/from ULP state is started for specific lanes, users must wait for the sequence to complete before changing the state of the same or other lanes.

7.5.4.12 DSI Programming Sequence Example

This section describes distinct configurations of the DSI protocol engine to support different type of traffics.

NOTE: When the VC is used to send video mode data from the video port, the DSS.DSI_VCn_CTRL[9] MODE_SPEED and the DSS.DSI_VCn_CTRL[1] SOURCE bits are ignored.

7.5.4.12.1 Video Mode Transfer

Description: One channel, video mode, no DMA requests, no bus turn-around.

1. Configure the display controller with the timing parameters.
2. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit is ignored by hardware
 - BTA_LONG_EN bit is set to 0: No BTA on long packet
 - BTA_SHORT_EN bit is set to 0: No BTA on short packet
 - MODE bit set to 1: The video mode is selected
 - MODE_SPEED bit is ignored by hardware
3. Configure the DSS.DSI_VM_TIMING1 to DSS.DSI_VM_TIMING7 registers.
4. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
5. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
6. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1.
7. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
8. Enable the LCD video output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1

CAUTION

The restriction for stopping the video mode is that no frame must be sent by the display controller (DISPC) after disabling video mode in DSI.

7.5.4.12.2 Command Mode Transfer Example 1

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, no DMA requests, manual bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit set to 0: The source is the L4 interconnect port
 - BTA_LONG_EN bit is set to 0: No automatic BTA on long packet

- BTA_SHORT_EN bit is set to 0: No automatic BTA on short packet
 - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1
 3. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
 4. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
 5. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
 6. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
For long packet:
 - Write the header value into the DSS.DSI_VCn_LONG_PACKET_HEADER register
 - Write the data into the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload. Repeat step until WC is reached (see DSI_VCn_LONG_PACKET_HEADER)
 For short packet:
 - Send short packets through the L4 interconnect: Write the header value into the DSS.DSI_VCn_SHORT_PACKET_HEADER register. Repeat step for each short packet.
 7. Send one or more packets through L4 interconnect:
 - Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
 - Write the data into DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload.
 - Repeat step 5 for all the long packets
 8. Send short packets through L4 interconnect:
 - Write the header value into DSS.DSI_VCn_SHORT_PACKET_HEADER register
 - Repeat step 6 for all the short packets
 9. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
 10. The applicative software forces the bus turn-around:
 - Wait until the PACKET_SENT_IRQ has happened as many times as the number of sent packets
 - Set the DSS.DSI_VCn_CTRL[6] BTA_EN bit to 1 to send manually a BTA
 - Wait until the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset to 0 by hardware
 11. Receive the packets from the peripheral
 - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
 - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one word in the RX FIFO

7.5.4.12.3 Command Mode Transfer Example 2

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, DMA request, automatic bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit set to 0: The source is the L4 interconnect port
 - BTA_LONG_EN bit is set to 1: Automatic BTA on long packet
 - BTA_SHORT_EN bit is set to 1: Automatic BTA on short packet
 - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1

3. Set the ForceTxStopMode bit to 1 in DSS.DSI_TIMING1 register.
4. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
5. Configure the TX FIFO threshold and DMA requests parameters:
 - Program the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field
 - Program the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field
6. Program the system DMA to be ready to send data to the L4 interconnect port
7. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
8. Poll the ForceTxStopMode bit to 0 in DSS.DSI_TIMING1 register.
9. Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
10. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
11. Receive the packets from the peripheral
 - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
 - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one 32-bit word in the RX FIFO
12. Repeat the steps 7 for all long packets.

7.5.5 DSI PLL Controller Basic Programming Model

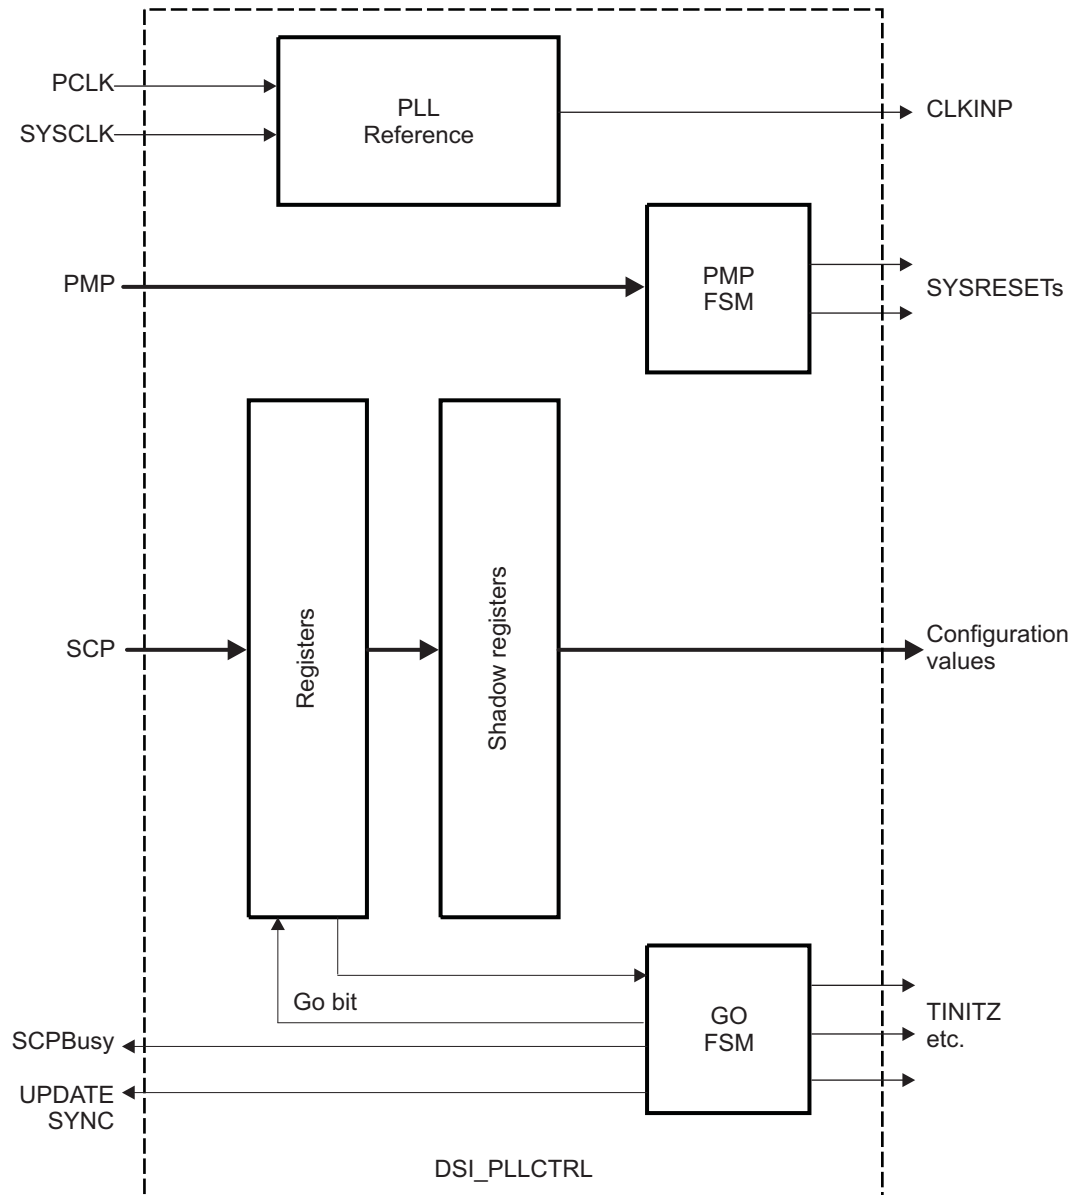

7.5.5.1 Software Reset

The DSI PLL control module does not have its own software reset. It is reset by the DSI protocol engine. Nevertheless, software users can monitor the reset status of the DSI PLL control module by reading the DSS.DSI_PLL_STATUS[0] DSI_PLLCTRL_RESET_DONE status bit.

7.5.5.2 DSI PLL Programming Blocks

[Figure 7-135](#) shows the DSI PLL programming blocks.

Figure 7-135. DSI PLL Programming Blocks

dss-181

7.5.5.3 DSI PLL Go Sequence

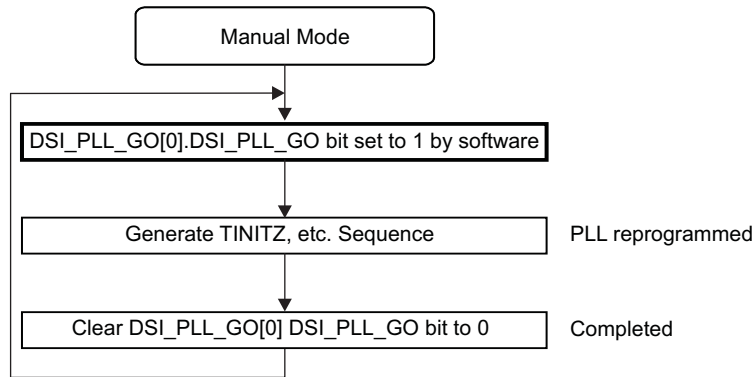

In Manual Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0), the DPLL requires a sequence on TINITZ, TENABLE and TENABLEDIV to update the configuration values and start the locking sequence.

Once all the configuration values have been programmed into the registers, the GO bit must be set. The appropriate sequence should then be sent on the TINITZ, TENABLE, and TENABLEDIV pins, respecting the timing requirements of the ADPLL. The DSS.DSI_PLL_GO[0] DSI_PLL_GO bit are cleared to 0 at the end of the sequence.

Because the TENABLEDIV signal is shared with the HSDIVIDER module, it is programmed at the same time. In this mode, software must deassert CLKINEN by unsetting the DSS.DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN to 0 and assert HSDIVBYPASS correctly by setting the DSS.DSI_PLL_CONFIGURATION2[20] DSI_HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting the DSI_PHY and display subsystem during PLL locking. In manual mode the shadow register must be updated anyway so that valid values are present when later selecting automatic mode.

Figure 7-136 shows the DSI PLL Go flow chart in manual mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0).

Figure 7-136. DSI PLL Go Sequence (Manual Mode)

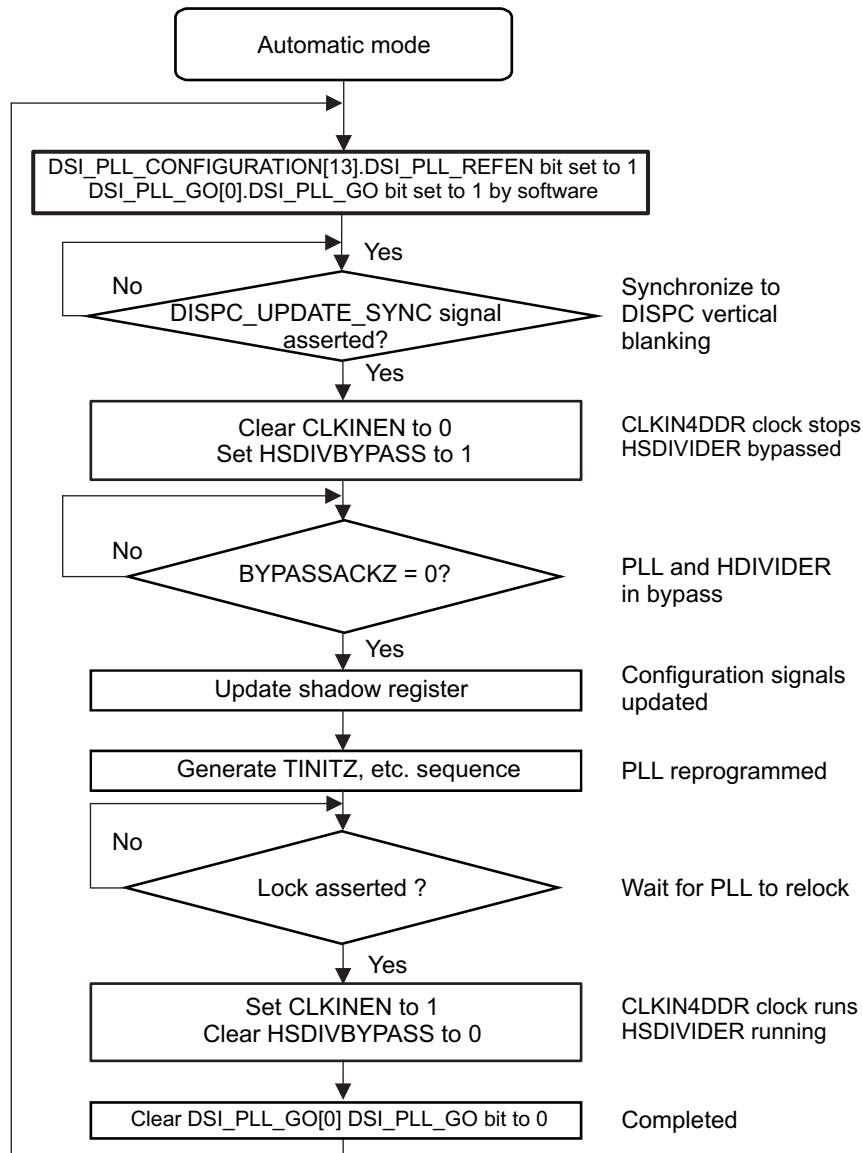

dss-182

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

In automatic mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1), the TINITZ, TENABLE and TENABLEDIV sequence and the update of the PLL configuration from the DSI_PLL_CONFIGURATION2 register are deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode CLKINEN, HSDIVBYPASS and REFEN are controlled automatically and the register value is overridden.

Figure 7-137 shows the DSI PLL Go flow chart in automatic mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1).

Figure 7-137. DSI PLL Go Sequence (Automatic Mode)

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

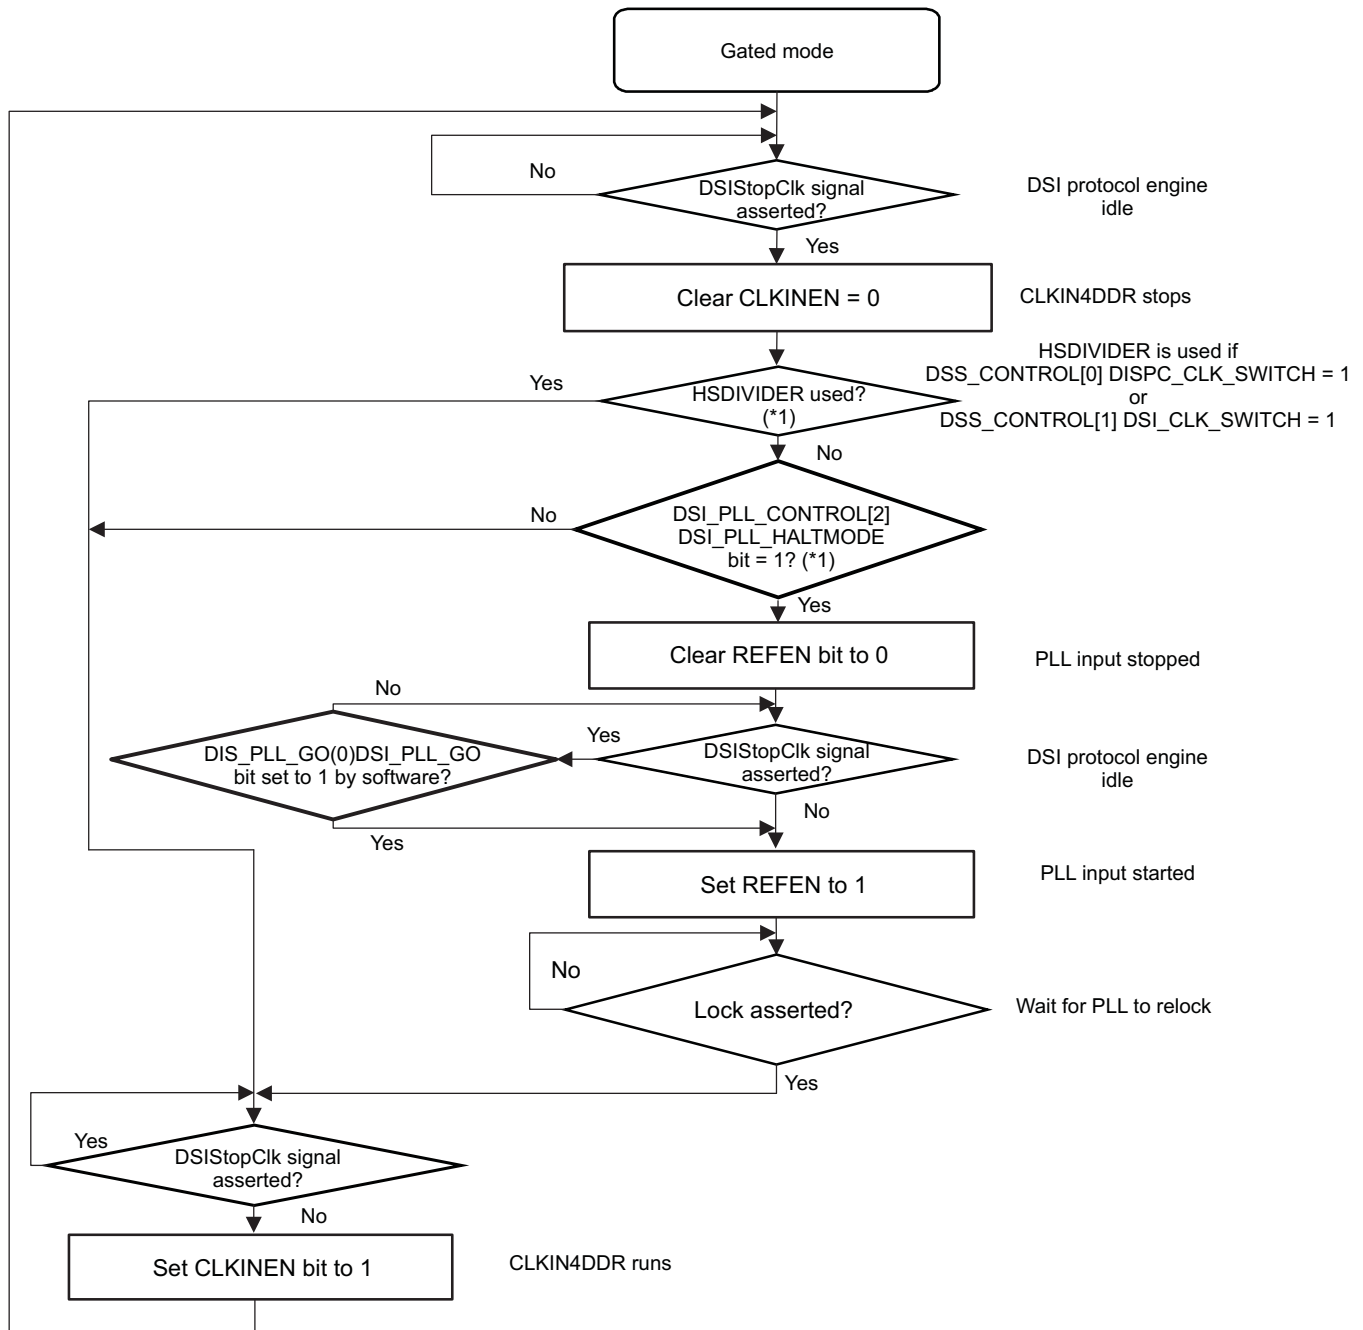

7.5.5.4 DSI PLL Clock Gating Sequence

Clock gating can be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engine can verify when the PLL has unstarted by inspecting the LOCK signal (DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit). Because TxByteClkHS is stopped when the CLKIN4DDR is stopped, this should obviate the need for any explicit feedback that the clock has been unstarted in the other case. This flow chart should run even if the DSS.DSI_PLL_GO[0] DSI_PLL_GO bit has not been set.

Figure 7-138 shows the DSI PLL gated mode sequence.

Figure 7-138. Gated Mode Sequence

NOTE: All thick-outlined blocks show operations performed by software.

dss-184

7.5.5.5 DSI PLL Lock Sequence

The DSI PLL (ADPLL) generates the CLKIN4DDR clock. The HSDIVIDER generates two clocks: DSI1_PLL_FCLK connected to the display controller (DISPC) and the DSI2_PLL_FCLK connected to the DSI protocol engine. If these two clocks are not used, the HSDIVIDER functions are not required.

The CLKIN4DDR is twice the data rate, and is four times the DSI output clock frequency. The DSI PLL factors need to be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programmed by DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM bit field
- REGN factor is programmed by DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field
- REGM3 factor is programmed by DSS.DSI_PLL_CONFIGURATION1[22:19] DSI_CLOCK_DIV bit field
- REGM4 factor is programmed by DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV bit field

Figure 7-139 shows the programming sequence.

Figure 7-139. DSI PLL Programming Sequence

camdss-190

NOTE:

- The REGM3 and REGM4 factors must according with the following conditions:
 - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be a multiple of the PCLK frequency (for proper settings of PCD and LCD factors in the DISPC).
 - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be lower than 173 MHz at nominal voltage (OPP100), and lower than 100 MHz at low voltage (OPP50).
- Most of the other DSI PLL programming values are available for software flexibility but it is not recommended to update the values in normal use. See [Section 7.5.5.7](#) for details on DSI PLL recommended values.

DSI PLL programming examples:

- WVGA Display on one data pair: Pixel clock (PCLK) = 30 MHz with 18-BPP pixel format

The data rate is $30 \times 18 = 540$ Mbps on one data lane. Therefore, the frequency on the data lane is twice the data rate: 1080 MHz.

The frequency on the clock lane is 270 MHz (1080 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL to 0b0.

Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ to 0b0 as PCLK is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field to 0xC.

To get the CLKIN4DDR to 1080 MHz, set the REGM factor to 270 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x10E.

$DSI_PHY = 2 \times 270/13 \times 26/1 = 1080$ MHz

Because DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiples of PCLK and also lower than 173 MHz at nominal voltage (OPP100), and lower than 100 MHz at low voltage (OPP50), program these frequencies to 90 MHz by setting the REGM3 and REGM4 factors to 11 (divide by 12). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV bit field and DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0xB:

$DSI1_PLL_FCLK = DSI2_PLL_FCLK = 1080/12 = 90$ MHz

- XGA Display on two data pairs: Pixel clock (PCLK) = 60 MHz with 16-BPP pixel format

The data rate is $(60 \times 16)/2 = 480$ Mbps on each data lane. Therefore, the frequency on the data lane is twice the data rate: 960 MHz.

The frequency on the clock lane is 240 MHz (960 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit to 0b0.

Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 0b0 as the source clock frequency (SYS_CLK in this example) is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field to 0xC.

To get the CLKIN4DDR to 960 MHz, set the REGM factor to 240 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x0F0.

$DSI_PHY = 2 \times 240/13 \times 26/1 = 960$ MHz

Because DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiples of PCLK and also lower than 173 MHz at nominal voltage (OPP100), program these frequencies to 120 MHz by setting the REGM3 and REGM4 factors to 7 (divide by 8). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV bit field and DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0x7:

$$\text{DSI1_PLL_FCLK} = \text{DSI2_PLL_FCLK} = 960/8 = 120 \text{ MHz}$$

7.5.5.6 DSI PLL Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- DSS.DSI_IRQSTATUS[9], PLL_RECAL_IRQ bit
- DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ
- DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ

The PLL_LOCK_IRQ interrupt indicates that the DSI PLL is locked. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL is unlocked. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL_RECAL_IRQ interrupt indicates that the DSI PLL must be recalibrated. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored:

- The DSS.DSI_PLL_STATUS[3] DSI_PLL_LOSSREF status bit informs if the DSI PLL has lost the reference.
- The DSS.DSI_PLL_STATUS[4] DSI_PLL_LIMP status bit informs about the DSI PLL limp status.

7.5.5.7 DSI PLL Recommended Values

Table 7-70 shows the DSI PLL recommended values.

Table 7-70. Recommended Programming Values

Field Name	Value	Description
DSI_HSDIV_SYSRESET	0	Allow power FSM to control
DSI_PLL_SYSRESET	0	Allow power FSM to control
DSI_PLL_HALTMODE	-	See Section 7.5.5.4 for details
DSI_PLL_GATEMODE	-	See Section 7.5.5.4 for details
DSI_PLL_AUTOMODE	-	See Section 7.5.5.4 for details
DSI_PLL_GO	1-0	Write a 1 when PLL is to be (re-)locked with new parameters. This bit is cleared by hardware when the PLL request has completed
DSIPROTO_CLOCK_DIV	See ⁽¹⁾	DSI protocol engine clock divider
DSS_CLOCK_DIV	See ⁽¹⁾	DSS clock divider
DSI_PLL_REGM	See ⁽¹⁾	Feedback clock divider
DSI_PLL_REGN	See ⁽¹⁾	Reference clock divider
DSI_PLL_STOPMODE	1	Required to use GATEMODE bit
DSI_HSDIVBYPASS	0	PLL is controlling HSDIVIDER bypass
DSI_PROTO_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSI_PROTO_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSI protocol clock source
DSS_CLOCK_PWDN	0	If PLL/HSDIVIDER is used as the DSS clock source
DSS_CLOCK_EN	1	If PLL/HSDIVIDER is used as the DSS clock source

⁽¹⁾ The bit field value must be set according to the desired clock frequency.

Table 7-70. Recommended Programming Values (continued)

Field Name	Value	Description
DSI_BYPASSEN	0	To use PLL as the clock source. For small displays it may be possible to use the DSS functional clock, in which case this bit must be set to 1
DSI_PHY_CLKINEN	1	Enable CLKIN4DDR
DSI_PLL_REFEN	1	Enable PLL reference
DSI_PLL_HIGHFREQ	0/1	Set to 1 if the clock reference is higher than 32 MHz (21 MHz if DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN = 0)
DSI_PLL_CLKSEL	0/1	Set to 0 to use DSS2_ALWON_FCLK as the PLL reference or set to 1 to use PCLKFREE as the PLL reference, in this case the DISPC must be using DSS1_ALWON_FCLK .
DSI_PLL_LOCKSEL	0x0	Phase lock criteria to lock the PLL
DSI_PLL_DRIFTGUARDEN	0x0	The RECAL status/interrupt must be used to decide when to perform a PLL uncalibration No automatic uncalibration is performed
DSI_PLL_TIGHTPHASELOCK	0	Normal criteria
DSI_LOWCURRSTDBY	0/1	Set to 0 for fast PLL unlock, but higher standby current Set to 1 for leakage level standby current, but longer unlock time
DSI_PLL_PLLLPMODE	0	Normal operation For smaller display sizes may be possible to set to 1
DSI_PLL_IDLE	0	PLL active

7.5.6 DSI Complex I/O Basic Programming Model

7.5.6.1 Software Reset

The clock domain using the TxByteClkHS from the DSI complex I/O has a dedicated reset done information in the [DSS.DSI_COMPLEXIO_CFG1\[29\]](#) [RESET_DONE](#) bit. The [DSS.DSI_SYSCONFIG\[1\]](#) [SOFT_RESET](#) bit is used to reset the TxByteClkHS power domain. A dummy read using the SCP interface to any [DSI_PHY](#) register is required after [DSI_PHY](#) reset to complete the reset of the DSI complex I/O.

7.5.6.2 Reset-Done Bits

The DSI complex I/O has several clock domains. The reset status for each clock domain is provided in [DSS.DSI_PHY_REGISTER5](#) register:

- [DSS.DSI_PHY_REGISTER5](#) [31] [RESETDONETXBYTECLK](#) bit : Reset done for the [TXBYTECLK](#) domain.
- [DSS.DSI_PHY_REGISTER5](#) [26:24] [RESETDONETXCLKESCI](#) bits: Reset done for the [TXCLKESC](#) domain for lane *i* (*i* between 0 and 2).
- [DSS.DSI_PHY_REGISTER5](#) [30] [RESETDONESCPCCLK](#) bit: Reset done for the SCP clock domain. Software users must perform a dummy read on this bit to initiate the reset sequence of the SCP finite state machine. When the reset sequence is complete, the [RESETDONESCPCCLK](#) signal goes high and software users can read again the [DSS.DSI_PHY_REGISTER5](#) [30] [RESETDONESCPCCLK](#) bit to ensure that the value is now 1.

NOTE: Software must not write in the [DSI_PHY_SCP](#) registers before the [DSS.DSI_PHY_REGISTER5](#) [30] [RESETDONESCPCCLK](#) bit is set to 1.

- **DSS.DSI_PHY_REGISTER5** [29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR finite state-machine is complete when the RESETDONEPWRCLK signal goes high.

7.5.6.3 Pad Configuration

The number of lanes is configurable through the **DSS.DSI_COMPLEXIO_CFG1** register.

It is not allowed to change on the fly the position (by modifying the **DATAi_POSITION** with $i = 1$ or 2 and **CLOCK_POSITION** bit fields), P/N order (Positive/Negative order of the differential pair by modifying the **DATAi_POL** with $i = 1$ or 2 and **CLOCK_POL**) or number of active data lanes (by modifying the **DSS.DSI_COMPLEXIO_CFG1**[10:8] **DATA2_POSITION** bit). To add or remove the lane #2, it is required to be in OFF mode for the DSI complex I/O.

The minimum requirement for the number of lanes is one clock lane and one data lane. Note that by default, the data lane 2 is not connected (the **DSS.DSI_COMPLEXIO_CFG1**[10:8] **DATA2_POSITION** bit reset value is 0).

7.5.6.4 Display Timing Configuration

NOTE: Copyright © 2005-2008 MIPI Alliance, Inc. All rights reserved. MIPI Alliance Member Confidential.

Depending on the **CLKIN4DDR** frequency settings programmed with the DSI PLL control module, software users must program accordingly the timing parameters in the DSI complex I/O registers.

7.5.6.4.1 High-Speed Clock Transmission

Figure 7-140 shows an example of high-speed Clock Transmission.

Figure 7-140. High-Speed Clock Transmission

dss-185

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXByteClkHS. The PHY detects this signal on the next rising edge, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Clock Transmission, these parameters are defined in multiples of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI_PHY_REGISTER1[20:16] REG_TLPXBY2 bit field.
- THS-PREPARE timing is programmed by the DSS.DSI_PHY_REGISTER0[31:24] REG_THSPREPARE bit field.
- TCLK-ZERO timing is programmed by the DSS.DSI_PHY_REGISTER1[7:0] REG_TCLKZERO bit field. TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The DSI_PHY detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

The DSI_PHY then goes through the LP End of Transmission (EoT) procedure. TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN4DDR and programmed by the following register fields:

- TCLK-TRAIL timing is programmed by the DSS.DSI_PHY_REGISTER1[15:8] REG_TCLKTRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI_PHY_REGISTER0[7:0] REG_THSEXIT bit field.

The DSI_PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

It requires that the high speed clock be present for some time before (TCLK-PRE) and some time after (TCLK-POST) high speed data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

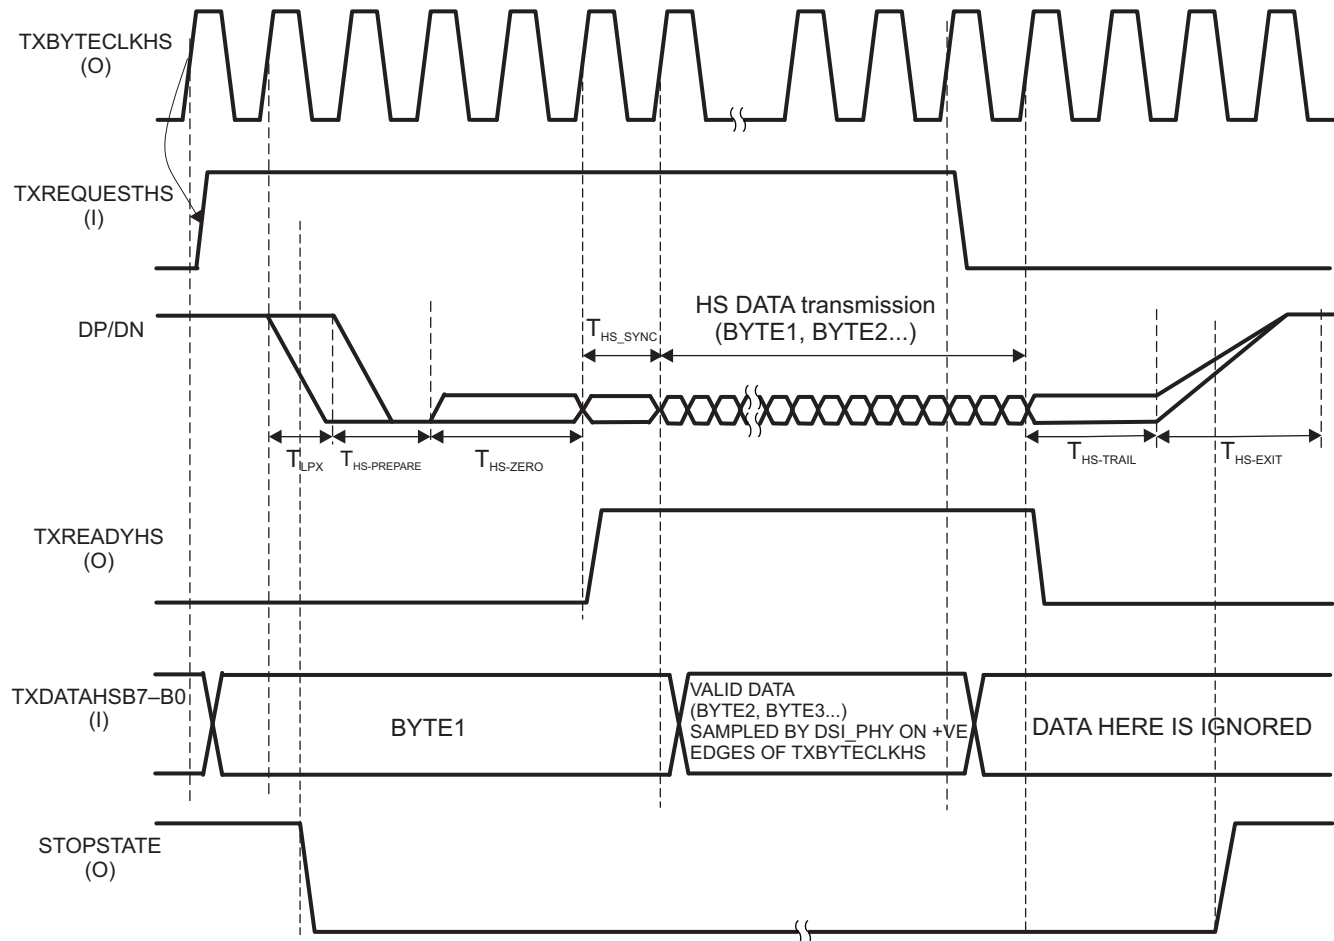

The PHY ensures that the clock signal has a quadrature-phase with respect to a toggling bit sequence on any Data Lane, and a rising edge in the center of the first transmitted bit of every Data byte. These relations are not described in the timing diagram.

CLKIN4DDR can be shut off 300ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN4DDR can be shut down after TCLK-Trail + THS-Exit + 2 Txbyteclk periods after TxRequestHS falling edge is received by DSI_PHY.

The DSI protocol engine must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

7.5.6.4.2 High-Speed Data Transmission

Figure 7-141 shows an example of high-speed Data Transmission.

Figure 7-141. High-Speed Data Transmission

dss-186

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXByteClkHS. It also makes TXREQUESTHS high the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXByteClkHS, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Data Transmission, these timings are multiple of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI_PHY_REGISTER1[20:16] REG_TLPXBY2 bit field.
- THS-PREPARE + THS-ZERO timing is programmed by the DSS.DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO bit field.

THS-ZERO will be extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles. THS-SYNC corresponds to the length of the sync pattern which is 8 high-speed bits, and can be configured through the DSI_PHY_REGISTER2[31:24] HSSYNCPATTERN bit field.

Towards the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXByteClkHS and then start accepting data from TXDATAHS from the next positive edge onwards. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXByteClkHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS Data Transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP End of Transmission (EoT) procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN4DDR and programmed by the following register bit fields:

- THS-TRAIL timing is programmed by the DSS.DSI_PHY_REGISTER0[15:8] REG_THSTRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI_PHY_REGISTER0[7:0] REG_THSEXIT bit field.

The PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the low power receivers. This signal is not synchronized with TXByteClkHS.

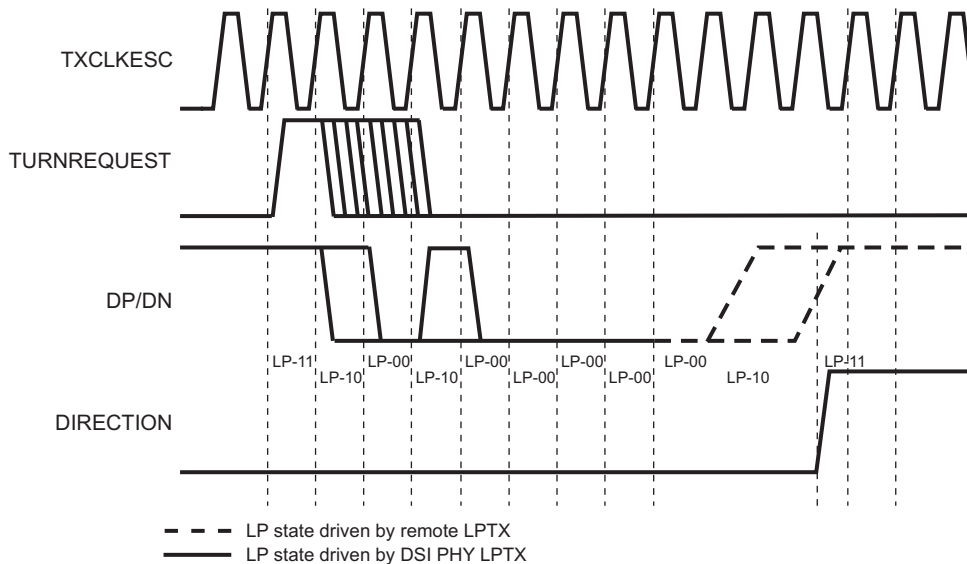

The protocol must ensure that TXREQUESTESC, TXULPSCLK, and TURNREQUEST are low whenever TXREQUESTHS is asserted.

7.5.6.4.3 Turn-Around Request in Transmit Mode

When the DSI PHY is in transmit mode, the DSI protocol engine can request a turnaround by making the TurnRequest signal high for at least one clock cycle of TxClkEsc (see Section 7.4.3.7.3, *TurnRequest FSM*).

The DSI PHY transmits the turn-around request pattern (LP 11-10-00-10-00-00-00-00) (see Figure 7-142). The number of 00 states in the end of the pattern is defined by T_{TA_GO} timing parameter and is programmable through the DSS.DSI_PHY_REGISTER1[31:29] REG_TTAGO bit field, in number of TxClkEsc clocks. Following the transmission of the pattern, the DSI PHY disables its LP transmitters and waits for an acknowledgment from the remote device. The remote device detects the turn-around request and acknowledges it by driving LP-10, followed by the STOP state. When this acknowledgment is received (BTA_IRQ is asserted, as described in Section 7.4.3.8, *Bus Turnaround*), DSI PHY switches to receive mode and indicates the completion of the turn-around procedure by changing the direction (BTA_EN = 0).

Figure 7-142. Turn-Around Request in Transmit Mode

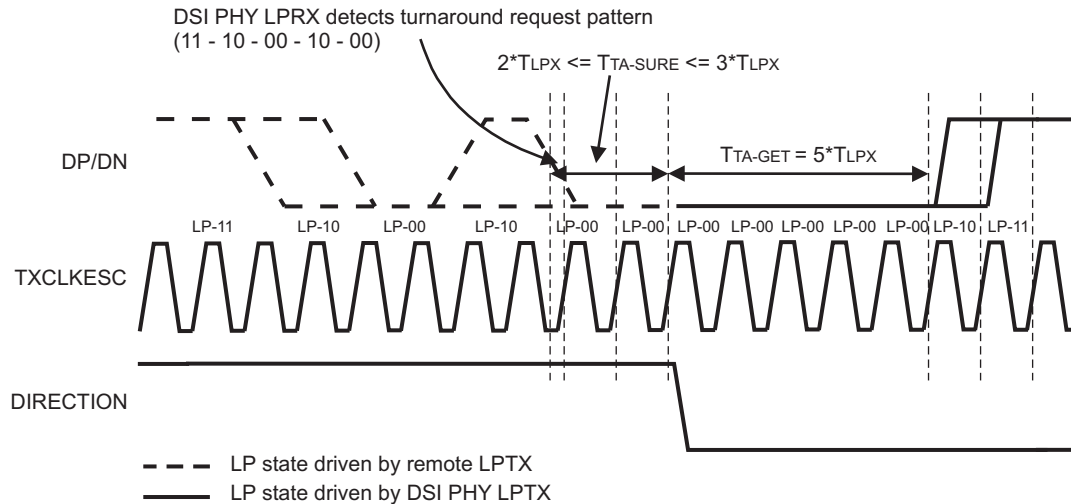

dss-401

The DSI protocol engine must not stop TxClkEsc after the turn-around process completes (the DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit must be kept at 1), because TxClkEsc is also used in handling a turn-around request transmitted by a remote slave device (see Section 7.5.6.4.4, *Turn-Around Request in Receive Mode*).

7.5.6.4.4 Turn-Around Request in Receive Mode

When the DSI PHY is in receive mode, an LP pattern of 11-10-00-10-00 on DP/DN lines indicates a turn-around request from the remote device (see Figure 7-143).

Figure 7-143. Turn-Around Request in Receive Mode

dss-402

If the line stays in LP-00 for a time $T_{TA-SURE}$, DSI PHY accepts the turn-around request, changes the direction, transmits LP-00 for a time T_{TA-GET} , and then transmits the acknowledgment pattern LP-10, followed by the STOP state.

This completes the turn-around procedure (BTA_IRQ is asserted, as described in [Section 7.4.3.8, Bus Turnaround](#)). The $T_{TA-SURE}$ and T_{TA-GET} timing parameters are programmable through [DSS.DSI_PHY_REGISTER1](#) in number of TxClkEsc clocks:

- $T_{TA-SURE}$ can be configured in the [28:27] REG_TTASURE bit field.
- T_{TA-GET} can be configured in the [26:24] REG_TTAGET bit field.

7.5.6.4.5 Other DSI_PHY Transmission and Reception

The timing of the following sequences defined in the DSI_PHY protocol cannot be programmed by users:

- Low-power data transmission
- Escape mode trigger command transmission
- ULP state command transmission on data lanes
- ULP state transmission on clock lane
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULP state command on clock lane in receive mode
- ULP state command on data lane in receive mode

7.5.6.5 Error Handling

A dedicated register for the DSI complex I/O, [DSS.DSI_COMPLEXIO_IRQSTATUS](#), indicates the state of each error provided by the DSI complex I/O error signals. The DSI_PHY reports the following errors:

- [DSS.DSI_COMPLEXIO_IRQSTATUS\[7:5\]](#) ERR_ESCi_IRQ: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- [DSS.DSI_COMPLEXIO_IRQSTATUS\[2:0\]](#) ERRSYNCESci_IRQ: If the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends, ERRSYNCESc is made high and remains high until the next change in line state.
- [DSS.DSI_COMPLEXIO_IRQSTATUS\[12:10\]](#) ERRCONTROLi_IRQ: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turn-around request or escape mode request is immediately followed by a Stop state instead of the required Bridge state, this signal is asserted and remains asserted until the next change in the line state.

- **DSS.DSI_COMPLEXIO_IRQSTATUS** ERRCONTENTIONLPO_i_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines low. Contention is detected only if it lasts at least 50ns
- **DSS.DSI_COMPLEXIO_IRQSTATUS** ERRCONTENTIONLP1_i_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines high. Contention is detected only if it lasts at least 50ns

The ULPSACTIVENOT signal goes low which indicates to the protocol that the PHY has entered ULP state. When all the ULPSActiveNot signals are low, the **DSS.DSI_COMPLEXIO_IRQSTATUS**[30] ULPSACTIVENOT_ALL0_IRQ event is generated. When all the ULPSActiveNot signals are high, the **DSS.DSI_COMPLEXIO_IRQSTATUS**[31] ULPSACTIVENOT_ALL1_IRQ event is generated.

When any of the events defined in **DSS.DSI_COMPLEXIO_IRQSTATUS** register happened, the **DSS.DSI_IRQSTATUS**[10] COMPLEXIO_ERR_IRQ bit is set to 1 at DSI protocol engine level.

The software must take appropriate action when receiving the interrupt indicating the error from the complex I/O. The action can be:

- Reset of the DSI protocol engine module
- Reset of the peripheral through reset trigger or directly driving the hardware reset pin of the display module
- Ignore the error

7.5.7 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

7.5.7.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The STALL mode is selected by setting the **DSS.DISPC_CONTROL**[11] STALLMODE bit. The **DSS.DISPC_CONTROL**[5] GOLCD bit must not be set to 1, but the display controller configuration (DMA engine, pipelines associated to the LCD output,..) must be set before enabling the LCD output by setting the **DSS.DISPC_CONTROL**[0] LCDENABLE bit to 1.
- To enable the hardware handcheck to avoid underflow, the **DSS.DISPC_CONTROL**[16] FIFOHANDCHECK must be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It must be disabled before resetting the **DSS.DISPC_CONTROL**[11] STALLMODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenables the LCD output to generate a new frame by setting the **DSS.DISPC_CONTROL**[0] LCDENABLE to 1. See [Figure 7-144](#).

7.5.7.2 RFBI Control Registers

The following registers define the RFBI control registers:

- **DSS.RFBI_CONTROL**
- **DSS.RFBI_PIXEL_CNT**
- **DSS.RFBI_LINE_NUMBER**

7.5.7.2.1 High Threshold

The DSS.RFBI_CONTROL[6:5] HIGHTHRESHOLD bit field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 x 32 FIFO depth) through the address of the register RFBI_DATA. It must be the size of the burst. The supported values are 4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the RFBI_DATA location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

NOTE: Software users can access the RFBI_DATA location without using the DMA request and without programming the high threshold value (backward mode).

7.5.7.2.2 Bypass Mode

Setting the DSS.RFBI_CONTROL[1] BYPASSMODE bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

7.5.7.2.3 Enable

Setting/resetting the DSS.RFBI_CONTROL[0] ENABLE bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT bit field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

Table 7-71. RFBI Behavior

RFBI_CONTROL[1] BYPASSMODE bit value	RFBI_CONTROL[0] ENABLE bit value	RFBI Behavior
0	0	L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active
0	1	The DISPC sends pixels to the RFB.

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenble the LCD output to generate a new frame by setting the DSS.DISPC_CONTROL[0] LCDENABLE to 1. See [Figure 7-144](#).

7.5.7.2.4 Configuration Selection

Setting the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the RFBI_CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only RFBI_CS0 is asserted to read data from the device connected on RFBI_CS0. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

7.5.7.2.5 ITE Bit

Set the DSS.[RFBI_CONTROL](#)[4] ITE bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the STALL mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (DSS.[RFBI_CONFIG](#)[3:2] TRIGGERMODE bit field set to 0x1 or 0x2) causes the DSS.[RFBI_CONTROL](#)[4] ITE bit to be ignored. The corresponding chip-select must be selected when this bit is set by users.

The RFBI_DISPC_STALL signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached
- End of the transfer (number of data to output)
- Reset of the RFBI module
- DSS.[RFBI_CONTROL](#)[0] ENABLE bit reset to 0x0

The RFBI_DISPC_STALL signal is deasserted when the DSS.[RFBI_CONTROL](#)[0] ENABLE bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External TE occurs and the DSS.[RFBI_CONFIG](#)[3:2] TRIGGERMODE bit field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.[RFBI_CONTROL](#)[4] ITE bit set to 0x1 by users (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

7.5.7.2.6 Number of Pixels to Transfer

Setting the DSS.[RFBI_PIXEL_CNT](#)[31:0] PIXELCNT bit field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.[RFBI_CONTROL](#)[0] ENABLE is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.[RFBI_CONTROL](#)[0] ENABLE bit is set and a new value is written in the DSS.[RFBI_PIXEL_CNT](#) register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if the DSS.[RFBI_CONFIG](#)[10:9] CYCLEFORMAT bit field is equal to 0x3 and the DSS.[RFBI_CONFIG](#)[8:7] L4FORMAT bit field is equal to 0x0, an even number of write accesses to the data register must be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When the DSS.[RFBI_CONFIG](#)[10:9] CYCLEFORMAT bit field is 0x3 (2 pixels are sent over 3 cycles), the number of pixels to be programmed in the DSS.[RFBI_PIXEL_CNT](#)[31:0] PIXELCNT bit field must be a multiple of 2. If another CYCLEFORMAT is used, the value for PIXELCNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.[RFBI_CONFIG](#)[10:9] CYCLEFORMAT bit field is equal to 0x3, the DSS.[RFBI_CONFIG](#)[8:7] L4FORMAT bit field is equal to 0, and back-to-back register write is processed. The following registers should be written after the first data: [RFBI_CMD](#), [RFBI_PARAM](#), [RFBI_READ](#), and [RFBI_STATUS](#). The whole data transfer must first be performed before being able to write to any other registers ([RFBI_CMD](#), [RFBI_PARAM](#), [RFBI_READ](#), and [RFBI_STATUS](#)).

7.5.7.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

7.5.7.3 RFBI Configuration

The following registers define the RFBI configuration:

- [DSS.RFBI_SYSCONFIG](#)
- [DSS.RFBI_SYSSTATUS](#)
- [DSS.RFBI_CONFIG0](#) (configuration 0) and [DSS.RFBI_CONFIG1](#) (configuration 1)
- [DSS.RFBI_VSYNC_WIDTH](#)
- [DSS.RFBI_HSYNC_WIDTH](#)

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the [RFBI_CONTROL\[3:2\]](#) CONFIGSELECT bit field).

7.5.7.3.1 Parallel Mode

The [DSS.RFBI_CONFIGi\[1:0\]](#) PARALLELMODE bit field (where $i = 0, 1$) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

7.5.7.3.2 Trigger Mode

Setting the [DSS.RFBI_CONFIG\[3:2\]](#) TRIGGERMODE bit field configures the trigger on the external TE signal ([RFBI_TE_VSYNC](#)), or external with VSYNC/HSYNC with the programmable number of HSYNCs to begin the transfer in both cases or the internal programmable [DSS.RFBI_CONTROL\[4\]](#) ITE bit.

7.5.7.3.3 VSYNC Pulse Width (Minimum Value)

The [DSS.RFBI_VSYNC_WIDTH\[15:0\]](#) MINVSNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

7.5.7.3.4 HSYNC Pulse Width (Minimum Value)

The [DSS.RFBI_HSYNC_WIDTH\[15:0\]](#) MINHSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

7.5.7.3.5 Cycle Format

Setting the [DSS.RFBI_CONFIGi\[10:9\]](#) CYCLEFORMAT bit field (with $i = 0, 1$) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- [DSS.RFBI_DATA_CYCLE_i](#) (if [DSS.RFBI_CONFIG\[10:9\]](#) CYCLEFORMAT bit field = 00) only
or
- [DSS.RFBI_DATA_CYCLE1_i](#) and [DSS.RFBI_DATA_CYCLE2_i](#) (if [DSS.RFBI_CONFIG\[10:9\]](#) CYCLEFORMAT bit field = 01)
or
- [DSS.RFBI_DATA_CYCLE1_i](#), [DSS.RFBI_DATA_CYCLE2_i](#), and [DSS.RFBI_DATA_CYCLE3_i](#) (if [DSS.RFBI_CONFIG\[10:9\]](#) CYCLEFORMAT bit field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the [DSS.RFBI_DATA_CYCLE_i](#) registers.

7.5.7.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFBI_CONFIGi[12:11] UNUSEDBITS bit field (with i = 0, 1) is used.

7.5.7.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field). Granularity is defined using the DSS.RFBI_CONFIGi[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to [Table 7-72](#) for the bits configuration values.

- Chip-select assertion/deassertion time

RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:

DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME bit field (with i = 0, 1).

The chip-select deassertion time from the start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME bit field (with i = 0, 1)

CAUTION

Configuring DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME = DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME = 0 (with i = 0, 1) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:

DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH bit field (with i = 0, 1)

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

- The DSS.RFBI_CYCLE_TIMEi [19] RRENABLE bit: Read-to-read access
- The DSS.RFBI_CYCLE_TIMEi [20] WWENABLE bit: Write-to-write access
- The DSS.RFBI_CYCLE_TIMEi [18] RWENABLE bit: Read-to-write access
- The DSS.RFBI_CYCLE_TIMEi [21] WRENABLE bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

The total access time is the time from when A0 becomes valid until data are sampled before deasserting the RE signal; access time is programmable:

DSS.RFBI_CYCLE_TIMEi[27:22] ACCESSTIME bit field (with i = 0, 1)

When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME, with i = 0, 1).

- Write enable cycle time

The total write enable cycle time is the time from when A0 becomes valid until write cycle completion; the write enable cycle time is programmable:

The DSS.RFBI_CYCLE_TIMEi[5:0] WECYCLETIME bit field (with i = 0, 1)

- Write enable assertion/deassertion time

The WE assertion delay time from start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[13:10] WEONTIME bit field (with i = 0, 1)

The WE deassertion delay time from the start access time is programmable:

DSS.RFBI_ONOFF_TIMEi[19:14] WEOFFTIME bit field (with i = 0, 1)

- Read enable cycle
The total read enable cycle time is the time when A0 becomes valid until read cycle completion; the read enable cycle time is programmable:
The DSS.RFBI_CYCLE_TIME_i[11:6] RECYCLETIME bit field (with i = 0, 1)
- Read enable assertion/deassertion time
The RE assertion delay time from the start access time is programmable:
DSS.RFBI_ONOFF_TIME_i[23:20] REONTIME bit field (with i = 0, 1)
The RE deassertion delay time from the start access time is programmable:
DSS.RFBI_ONOFF_TIME_i[29:24] REOFFTIME bit field (with i = 0, 1)

At cycle time completion (read access or write access) all control signals (RFBI_CSi, RFBI_WR, and RFBI_RD, with i = 0, 1) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the DSS.RFBI_CYCLE_TIME_i[17:12] CSPULSEWIDTH bit field = 0, with i = 0, 1), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CSi, RFBI_WR, and RFBI_RD, with i = 0, 1) stay asserted. This is applicable to any read/write-to-read/write access combination.

Table 7-72 summarizes the configurations values for each timing bit.

Table 7-72. RFBI Timings Configuration

Configuration bits ⁽¹⁾	Granularity ⁽²⁾	
	one	two
DSS.RFBI_ONOFF_TIME _i [3:0] CSONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [9:4] CSOFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [17:12] CSPULSEWIDTH	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [27:22] ACESSTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [5:0] WECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIME _i [13:10] WEONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [19:14] WEOFFTIME	0 to 63	0 to 126
DSS.RFBI_CYCLE_TIME _i [11:6] RECYCLETIME	0 to 63	0 to 126
DSS.RFBI_ONOFF_TIME _i [23:20] REONTIME	0 to 15	0 to 30
DSS.RFBI_ONOFF_TIME _i [29:24] REOFFTIME	0 to 63	0 to 126

⁽¹⁾ Where i = 0 or 1.

⁽²⁾ Number of L4Clk cycles. The granularity can be configured using the DSS.RFBI_CONFIG[4] TIMEGRANULARITY bit.

7.5.7.3.8 RFBI State-Machine

Referring to Table 7-39, the signals RFBI_A0, RFBI_RD, and RFBI_WR are asserted/deasserted based on the register accessed (DSS.RFBI_CMD, DSS.RFBI_PARAM, DSS.RFBI_DATA, DSS.RFBI_READ, and DSS.RFBI_STATUS). When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The DSS.RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the register RFBI_DATA only.

- Command register
Write a command at a time by writing in the DSS.RFBI_CMD register. If the previous command is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and the access to writing a new command is stalled.
- Parameter register

Write a parameter at a time by writing in the `DSS.RFBI_PARAM` register.

If the previous parameter is not processed, the `DSS.RFBI_SYSSTATUS[8]` BUSY bit is set by hardware and the access to writing a new parameter is stalled.

- Data register

Write one or two pixels at a time by writing in the `RFBI_DATA` register (when `DSS.RFBI_CONFIGi[10:9]` CYCLEFORMAT = 0x3 with $i = 0, 1$, two pixels must be written contiguously, no other access to RFBI registers except `DSS.RFBI_DATA` is allowed).

The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the `DSS.RFBI_CONFIGi[8:7]` L4FORMAT bit field indicates the number of pixels for each L4 access to the register and the order of the pixels

If the previous data are not processed, the `DSS.RFBI_SYSSTATUS[8]` BUSY bit is set by hardware and any access for writing new data is stalled. When the `DSS.RFBI_SYSSTATUS[8]` BUSY bit is reset by hardware, the access is not stalled.

- Read/status register

Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the `DSS.RFBI_READ` or `DSS.RFBI_STATUS` registers. In this case, the `DSS.RFBI_SYSSTATUS[8]` BUSY bit is set until the data are available in the register.

When the `DSS.RFBI_SYSSTATUS[8]` BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the `DSS.RFBI_SYSSTATUS[8]` BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

7.5.7.3.9 RFBI Configuration Flow Charts

The RFBI configuration depends on the trigger mode used by the application. The available trigger modes are:

- Internal trigger mode when setting the `DSS.RFBI_CONFIGi[3:2]` TRIGGERMODE bit field to 0x0
- External trigger mode:
 - TE external trigger mode when setting the `DSS.RFBI_CONFIGi[3:2]` TRIGGERMODE bit field to 0x1
 - HSYNC/VSYNC external trigger mode when setting the `DSS.RFBI_CONFIGi[3:2]` TRIGGERMODE bit field to 0x2

[Figure 7-144](#) gives an example of how to program and use the RFBI module:

Figure 7-144. How to Use RFBI

dss-192

Figure 7-145 details how to configure the RFBI registers:

Figure 7-145. RFBI Initial Configuration

Figure 7-146 describes how to enable the RFBI module.

dss-193

Figure 7-146. RFBI Output Enable

dss-324

7.5.8 Video Encoder Basic Programming Model

7.5.8.1 Video Encoder Software Reset

By setting the DSS.VENC_F_CONTROL[8] RESET bit to 1, the video encoder is reset. This bit is automatically cleared by hardware when the reset is done.

NOTE: Before changing the standard (NTSC or PAL) and all the related registers, a software reset is required to properly initialize the VENC module.

7.5.8.2 Video DAC Stage Settings

The video output format can be either:

- one composite video (CVBS) output signal with video DAC1 or

- two separated luma/chroma output signals with both video DAC1(luma analog signal) and DAC2 (chroma analog signal)

Selection is performed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit:

- When VENC_OUT_SEL bit is set to 0 (reset value), video DAC1 is selected for composite video (CVBS) signal
- When VENC_OUT_SEL bit is set to 1, video DAC1 is selected for luma signal

One of the first VENC settings is to enable the outputs of the video DACs. This setting depends on the video output format:

- CVBS video output format: Enable video DAC1 composite output by setting the DSS.VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE bit to 1
- Separated luma/chroma output format: Enable video DAC1 luma output by setting the DSS.VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit to 1 and enable video DAC2 chroma output by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 1

Table 7-73 shows different configurations for the analog TV output, along with the respective values to be set in the dedicated registers inside the device system control module.

Table 7-73. Analog TV Output Modes

Control Register	Analog TV output modes			
	Composite DC-coupled mode, high full scale	Composite AC-coupled mode, low full scale	S-Video DC-coupled mode, high full scale	Bypass mode, dual channels
CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS	0: Buffer Mode	0: Buffer mode	0: Buffer mode	1: Bypass mode
CONTROL.CONTROL_DEVCONF1[11] TVACEN	0: DC-coupling	1: AC-coupling	0: DC-coupling	0: DC-coupling
AVDAC1				
CONTROL.CONTROL_AVDAC1 [20] AVDAC1_COMP_EN	0: Don't care	0: Don't care	0: Don't care	0: Don't care
CONTROL.CONTROL_AVDAC1 [19] AVDAC1_COMP_EN	0: Single channel	0: Single channel	1: Dual channel	1: Dual channel
CONTROL.CONTROL_AVDAC1 [18] AVDAC1_COMP_EN	0: Composite	0: Composite	0: Luma	0: Luma
CONTROL.CONTROL_AVDAC1 [17] AVDAC1_COMP_EN	0: Full scale (1.3V)	1: Full scale (0.88V)	0: Full scale (1.3V)	0: Full scale (1.3V)
CONTROL.CONTROL_AVDAC1 [16] AVDAC1_COMP_EN	0: External current reference	0: External current reference	0: External current reference	0: External current reference
AVDAC2				
CONTROL.CONTROL_AVDAC2 [20] AVDAC2_COMP_EN	0: Don't care	0: Don't care	0: Don't care	0: Don't care
CONTROL.CONTROL_AVDAC2 [19] AVDAC2_COMP_EN	0: Single channel	0: Single channel	1: Dual channel	1: Dual channel
CONTROL.CONTROL_AVDAC2 [18] AVDAC2_COMP_EN	1: Chroma	1: Chroma	1: Chroma	1: Chroma
CONTROL.CONTROL_AVDAC2 [17] AVDAC2_COMP_EN	0: Full scale (1.3V)	0: Full scale (1.3V)	0: Full scale (1.3V)	0: Full scale (1.3V)
CONTROL.CONTROL_AVDAC2 [16] AVDAC2_COMP_EN	0: External current reference	0: External current reference	0: External current reference	0: External current reference

7.5.8.3 Video Encoder Programming Sequence

1. Set the DSS.VENC_F_CONTROL[8] RESET bit to 1 to perform a software reset of the VENC module.
2. Before any configuration change, save the DSS.DISPC_IRQENABLE register value (DSS interrupts context), and then disable the display subsystem interrupts by setting the DSS.DISPC_IRQENABLE register to 0x0000.
3. Configure the video encoder registers as described in Table 7-74, depending on the video standard used (PAL or NTSC). The DSS.VENC_F_CONTROL and DSS.VENC_SYNC_CTRL registers must be the last ones to be changed by software.
4. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
5. Wait for the first VSYNC pulse signal.
6. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
7. Set the DSS.DISPC_IRQENABLE register to the value saved in step 2 (restore the DSS interrupts context).

7.5.8.4 Video Encoder Register Settings

For video encoder programming, see Table 7-74. This table lists the register values to use in standard applications. These values are validated programming values only for the TV display support (NTSC 601 and PAL 601 standards).

Table 7-74. Video Encoder Register Programming Values

Register Name	NTSC 601	PAL 601
VENC_F_CONTROL	0x00000000	0x00000000
VENC_VIDOUT_CTRL	0x00000001	0x00000001

VENC_OUTPUT_TEST	0x00000000	0x00000000

NOTE: The following display controller registers must be programmed to the NTSC 601 video standard:

DSS.DISPC_SIZE_DIG[10:0] PPL = 720 - 1 = 719 = 0x2CF

DSS.DISPC_SIZE_DIG[26:16] LPP = (482/2) - 1 = 240 = 0xF0

DSS.DISPC_GFX_BA0 or DSS.DISPC_VIDn_BA0 = Base address of even bit field data

DSS.DISPC_GFX_BA1 or DSS.DISPC_VIDn_BA1 = Base address of odd bit field data

7.6 Display Subsystem Use Cases and Tips

This section gives some generic use cases and tips for setting the modules of the display subsystem.

7.6.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the display controller (DISPC). The scaling unit is a part of the video pipeline is used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously.

7.6.1.1 Filtering

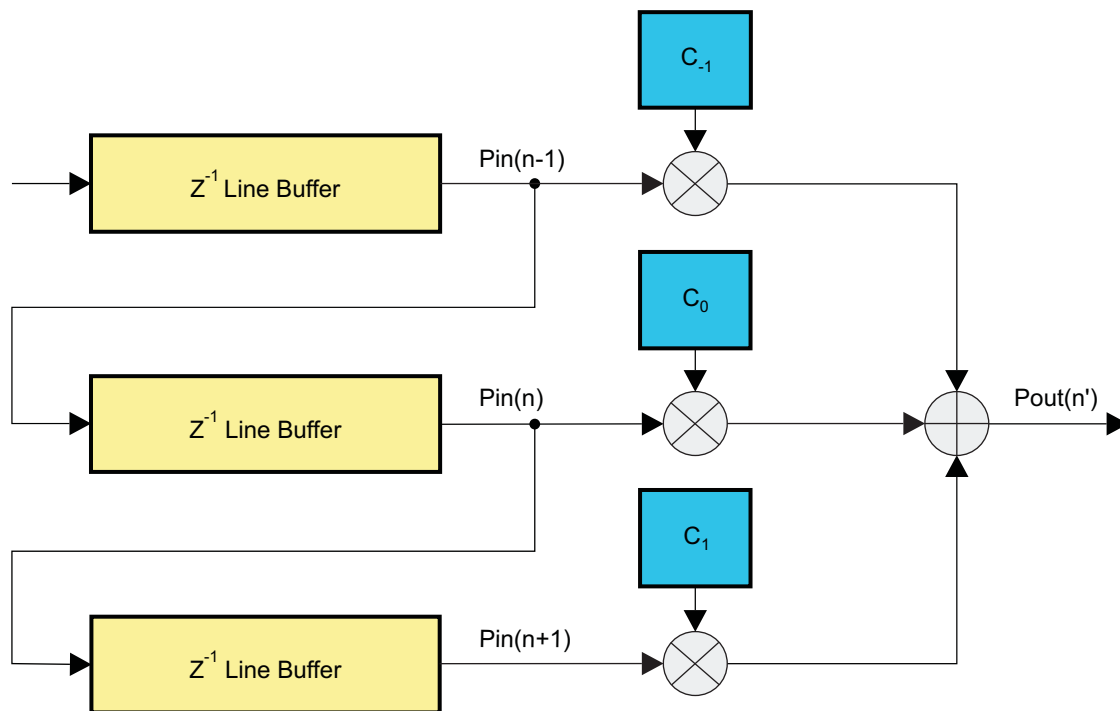

The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

7.6.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable.

The vertical 3-tap filtering macro architecture is shown in [Figure 7-147](#).

Figure 7-147. Vertical Filtering Macro Architecture (Three Taps)

dss-112

For the 3-tap vertical up/downsampling the equation is (with the example of R component):

$$R_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E067

(14)

Legend:

- Rout: R component output
- C_i(): Vertical FIR coefficients
- Rin: R component input
- The line (n+1) is older than line (n).

NOTE: If the 5-tap resizer is used for RGB16 and YUV4:2:2 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

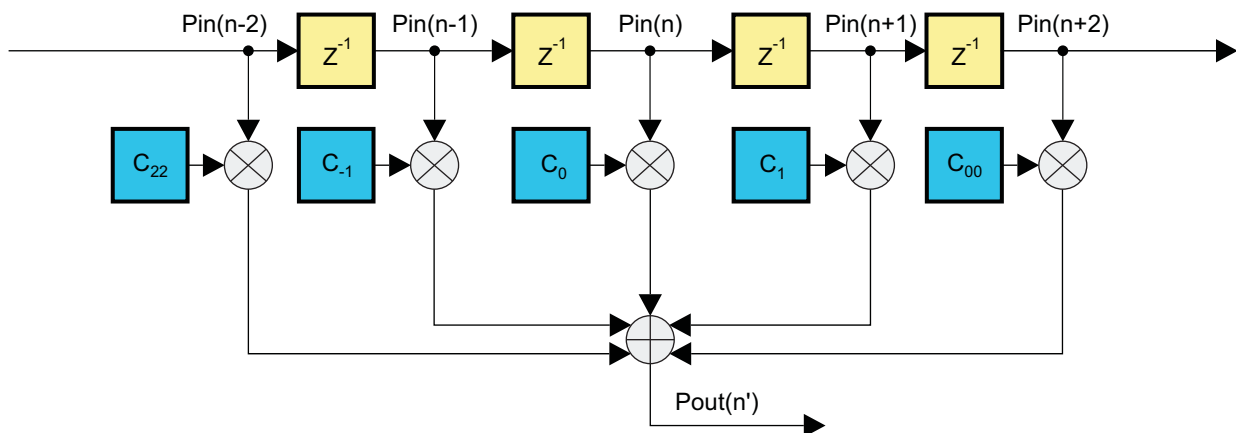

```
DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX 4 and even
```

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(), which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in Figure 7-148.

Figure 7-148. Vertical Filtering Macro Architecture (Five Taps)

dss-113

For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times Rin(n+i) \right) \ggg 7$$

dss-E066

(15)

Legend:

- Rout: R component output
- C_i(): Vertical FIR coefficients with C₊₂()=C₀₀() and C₋₂()=C₂₂()
- Rin: R component input
- The line (n+1) is older than line (n).

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(), which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

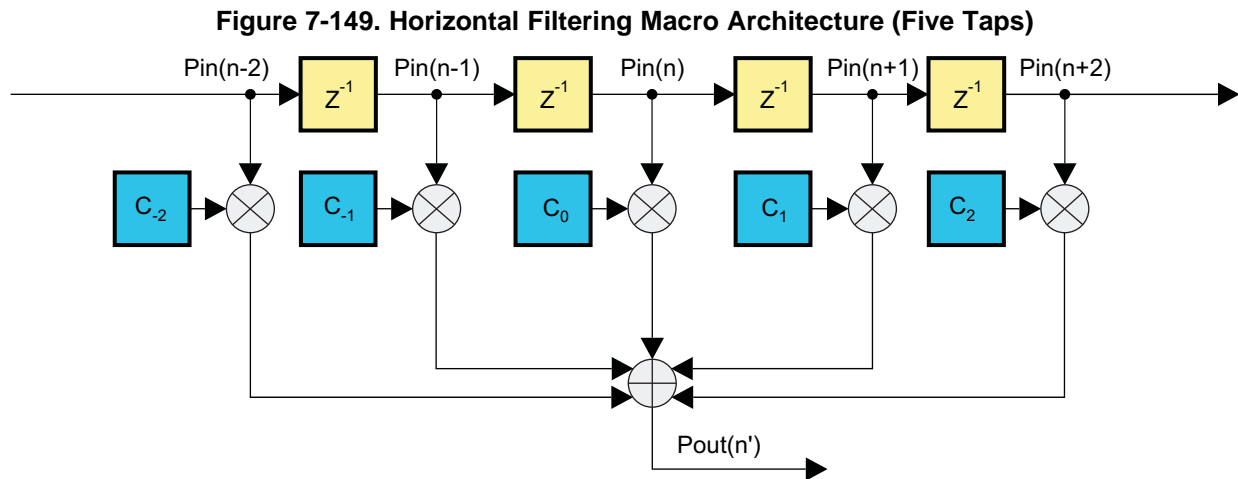

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

7.6.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in [Figure 7-149](#).

dss-114

For the 5-tap horizontal up/downsampling, the equation is (with the example of R component):

$$R_{out}(n) = \left(\sum_{i=-3}^{i=3} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E115

(16)

Legend:

- R_{out}: R component output
- C_i(Φ): Vertical FIR coefficients
- R_{in}: R component input
- The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(Φ), which is unsigned).

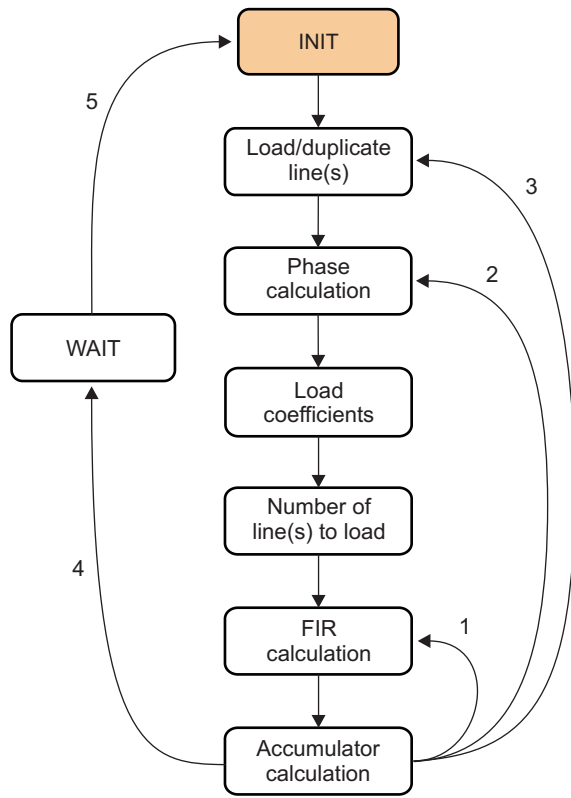

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

7.6.1.2 Scaling Algorithms

The up/downsampling finite state machines (FSM) below are detailed in this section.

[Figure 7-150](#) presents the vertical up/downsampling FSM.

Figure 7-150. Vertical Up-/Down-Sampling Algorithm

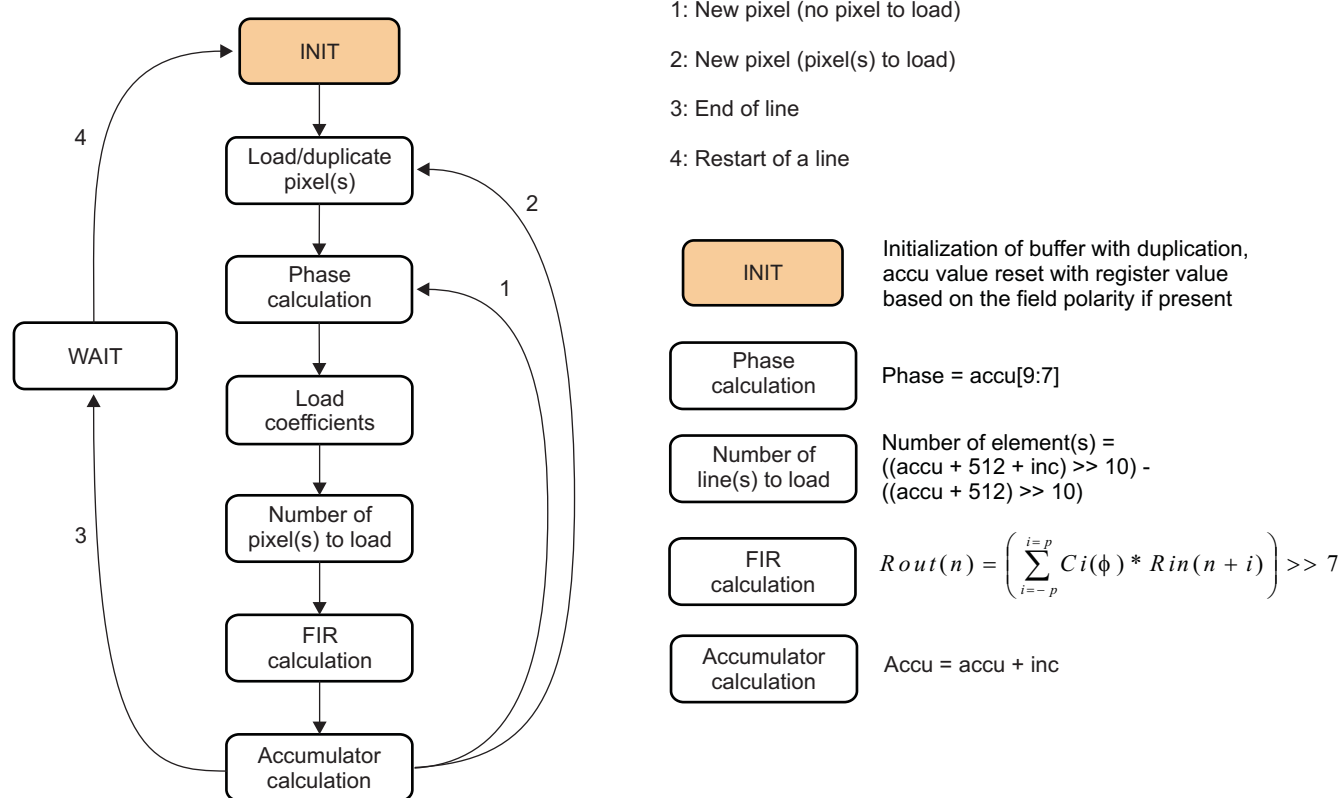

- 1: New pixel on the same line
- 2: New pixel on following line (no line to load)
- 3: New pixel on following line (line[s] to load)
- 4: End of frame
- 5: Restart of a new frame

INIT	Initialisation of buffer with duplication, accu value reset with register value based on the field polarity if present
Phase calculation	Phase = accu[9:7]
Number of line(s) to load	Number of element(s) = ((accu + 512 + inc) >> 10) - ((accu + 512) >> 10)
FIR calculation	$Rout(n) = \left(\sum_{i=-p}^{i=p} Ci(\phi) * Rin(n+i) \right) >> 7$
Accumulator calculation	Accu = accu + inc

dss-116

Figure 7-151 presents the horizontal up/downsampling FSM.

Figure 7-151. Horizontal Up-/Down-Sampling Algorithm

dss-117

7.6.1.3 Scaling Settings

NOTE:

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

7.6.1.3.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- DSS.DISPC_VIDn_BAj
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_ACCUJ
- DSS.DISPC_VIDn_FIR_COEF_Hi
- DSS.DISPC_VIDn_FIR_COEF_HVi
- DSS.DISPC_VIDn_FIR_COEF_Vi

Table 7-75 lists the registers for programming the vertical FIR coefficients (3-tap configuration).

Table 7-75. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration)

$C_x()$	VidFIRVC _x ()
$C_{-1}()$	VidFIRVC ₂ ()
$C_0()$	VidFIRVC ₁ ()

Table 7-75. Vertical FIR Coefficients Corresponding Table (3-Tap Configuration) (continued)

$C_x()$	VidFIRVC $_x()$
$C_1()$	VidFIRVC $_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- VidFIRVC $_2()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[31:24] VIDFIRVC2
- VidFIRVC $_1()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[23:16] VIDFIRVC1
- VidFIRVC $_0()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[15:8] VIDFIRVC0

Table 7-76 lists the registers for programming the vertical FIR coefficients (5-tap configuration).

Table 7-76. Vertical FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	VidFIRVC $_x()$
$C_{22}()$	VidFIRVC $_{22}()$
$C_{-1}()$	VidFIRVC $_2()$
$C_0()$	VidFIRVC $_1()$
$C_1()$	VidFIRVC $_0()$
$C_{00}()$	VidFIRVC $_{00}()$

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- VidFIRVC $_{22}()$ = DSS.DISPC_VIDn_FIR_COEF_Vi[15:8] VIDFIRVC22
- VidFIRVC $_2()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[31:24] VIDFIRVC2
- VidFIRVC $_1()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[23:16] VIDFIRVC1
- VidFIRVC $_0()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[15:8] VIDFIRVC0
- VidFIRVC $_{00}()$ = DSS.DISPC_VIDn_FIR_COEF_Vi[7:0] VIDFIRVC00

Table 7-77 lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

Table 7-77. Horizontal FIR Coefficients Corresponding Table (5-Tap Configuration)

$C_x()$	VidFIRHC $_x()$
$C_{-2}()$	VidFIRHC $_4()$
$C_{-1}()$	VidFIRHC $_3()$
$C_0()$	VidFIRHC $_2()$
$C_1()$	VidFIRHC $_1()$
$C_2()$	VidFIRHC $_0()$

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- VidFIRHC $_4()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[7:0] VIDFIRHC4
- VidFIRHC $_3()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[31:24] VIDFIRHC3
- VidFIRHC $_2()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[23:16] VIDFIRHC2
- VidFIRHC $_1()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[15:8] VIDFIRHC1
- VidFIRHC $_0()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[7:0] VIDFIRHC0

7.6.1.3.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[0].VIDENABLE bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up/downsampling block for the video pipeline #n is programmed by setting the DSS.DISPC_VIDn_ATTRIBUTES[6:5] VIDRESIZEENABLE bit field:

- When the VIDRESIZEENABLE[1] bit is set to 1, the video vertical up/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the VIDRESIZEENABLE[0] bit is set to 1, the video horizontal up/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the VIDRESIZEENABLE[1:0] is set to 0x3, both horizontal and vertical resize processing are enabled.

NOTE:

- Set a valid configuration before enabling the video up/downsampling block.
- Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See [Section 7.6.1.3.5](#) for more information concerning the filter coefficients.

7.6.1.3.3 Factor

The following register bit fields define the increment value of the video up/downsampling block for video pipeline n:

- Vertical up/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEY}[10:0]}{\text{VIDSIZEY}[10:0]} \quad \text{dss-E118} \quad (17)$$

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
 - The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.
- Horizontal up/downsampling increment value (the DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEX}[10:0]}{\text{VIDSIZEX}[10:0]} \quad \text{dss-E119} \quad (18)$$

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
- The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.

7.6.1.3.4 Initial Phase

- Vertical up/downsampling accumulator value DSS.DISPC_VIDn_ACCUI[25:16] VIDVERTICALACCU bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.

- Vertical up/downsampling accumulator value DSS.DISPC_VIDn_ACCUI[9:0] VIDHORIZONTALACCU

bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

[Table 7-78](#) lists the vertical/horizontal accumulator values and phases

Table 7-78. Vertical/Horizontal Accumulator Phase

Accumulator Value	Phases
0	0
128	1
256	2
384	3
512	4
640	5
768	6
896	7

NOTE: For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

7.6.1.3.5 Coefficients

- **Vertical up/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V)**

The 3-tap vertical up/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).

In addition, there are 2-tap vertical up/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients ($C_{22}()$ and $C_{00}()$).

In case of 5-tap configuration, both sets of registers, DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V, are used. In case of 3-tap configuration, only one set of registers, DSS.DISPC_VIDn_FIR_COEF_HV, is used.

- **Horizontal up/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HV)**

The 5-tap horizontal up/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up/downsampling block.

Each DSS.DISPC_VIDn_FIR_COEF_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.DISPC_VIDn_FIR_COEF_HVi contains one 8-bit signed coefficient.

[Table 7-79](#) through [Table 7-84](#) give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

7.6.1.3.5.1 Up-Sampling

[Table 7-79](#) gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

Table 7-79. Up-Sampling Vertical Filter Coefficients (Three Taps)

Phases	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()
0	0	128	0
1	3	123	2
2	12	111	5
3	32	89	7
4	0	64	64
5	7	89	32
6	5	111	12
7	2	123	3

Table 7-80 gives the 40 coefficients to program the vertical upsampling (5-tap configuration).

Table 7-80. Up-Sampling Vertical Filter Coefficients (Five Taps)

Phases	VidFIRVC ₂₂ ()	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()	VidFIRVC ₀₀ ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1

5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

Table 7-81 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

Table 7-81. Up-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC ₄ ()	VidFIRHC ₃ ()	VidFIRHC ₂ ()	VidFIRHC ₁ ()	VidFIRHC ₀ ()
0	0	0	128	0	0
1	-1	13	124	-8	0
2	-2	30	112	-11	-1
3	-5	51	95	-11	-2
4	0	-9	73	73	-9
5	-2	-11	95	51	-5
6	-1	-11	112	30	-2
7	0	-8	124	13	-1

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x037B02FF
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x0C6F05FE
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x205907FB
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x00404000

- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x075920FE
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x056F0CFF
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x027B0300

NOTE: In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x0D7CF8FF
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x0000FF00
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x1E70F5FE
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x0000FEFF
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x335FF5FB
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x0000FBFE
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0xF7404000
- DSS.DISPC_VIDn_FIR_COEF_V04 = 0x000000F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0xF55F33FE
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000FEFB
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0xF5701EFF
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FFFE
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0xF87C0D00
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x000000FF

7.6.1.3.5.2 Down-Sampling

Table 7-82 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

Table 7-82. Down-Sampling Vertical Filter Coefficients (Three Taps)

Phases	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()
0	36	56	36
1	40	57	31
2	45	56	27
3	50	55	23
4	18	55	55
5	23	55	50
6	27	56	45

Table 7-82. Down-Sampling Vertical Filter Coefficients (Three Taps) (continued)

Phases	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()
7	31	57	40

Table 7-83 gives the 40 coefficients to program the vertical downsampling (5-tap configuration).

Table 7-83. Down-Sampling Vertical Filter Coefficients (Five Taps)

Phases	VidFIRVC ₂₂ ()	VidFIRVC ₂ ()	VidFIRVC ₁ ()	VidFIRVC ₀ ()	VidFIRVC ₀₀ ()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5

4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

Table 7-84 gives the 40 coefficients to program the horizontal downsampling (5-tap configuration).

Table 7-84. Down-Sampling Horizontal Filter Coefficients (Five Taps)

Phases	VidFIRHC ₄ ()	VidFIRHC ₃ ()	VidFIRHC ₂ ()	VidFIRHC ₁ ()	VidFIRHC ₀ ()
0	0	36	56	36	0
1	4	40	55	31	-2
2	8	44	54	27	-5
3	-12	48	53	22	-7
4	-9	17	52	51	17
5	-7	22	53	48	12
6	-5	27	54	44	8
7	-2	31	55	40	4

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28391F04
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2D381B08
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3237170C
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x123737F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x173732F9
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B382DFB
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804

- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3928FE

NOTE:

- In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.
 - In this case, the downsampling factor must be higher than 1/2.
-

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28371F04
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x000004FE
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2C361B08
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x000008FB
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3035160C
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x00000CF9
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x113433F7
- DSS.DISPC_VIDn_FIR_COEF_V4 = 0x0000F711
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x163530F9
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000F90C
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B362CFB
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FB08
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3728FE
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x0000FE04

NOTE: This configuration must be used for vertical downsampling factors between 1/2 and 1/4

7.6.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On the device platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

7.6.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.
- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

NOTE: In the device, the display subsystem has its own power domain (the DSS power domain).

7.6.2.2 Display Subsystem Clock

7.6.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains two possible functional clock sources, DSS functional clock 1 (DSS1_ALWON_FCLK) and DSI PLL functional clock 1 (DSI1_PLL_FCLK):

- DSS1_ALWON_FCLK is sourced from DPLL4 (DPLL4_ALWON_FCLK), with several multipliers available and is configured in the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.
- DSI1_PLL_FCLK is one of the two output clocks from the DSI PLL.

The pixel clock is set as either DSS1_ALWON_FCLK or DSI1_PLL_FCLK by configuring the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit

NOTE: When the DSI PLL is in bypass mode, the DSI1_PLL_FCLK clock is the DSS2_ALWON_FCLK clock. This ensures the backward compatibility with OMAP2 devices.

The LCD logic clock is determined by the DSS.DISPC_DIVISOR[23:16] LCD bit field. This divisor is used on the DSS functional clock that is selected in the DSS_CONTROL register (either DSS1_ALWON_FCLK or DSS2_ALWON_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.DISPC_DIVISOR[7:0] PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4_ALWON_FCLK) is enabled and running at 266 MHz:

The PRCM.CM_CLKSEL2_PLL[19:8] PERIPH_DPLL_MULT bit field is set to 0x4 and the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field is set to 0x1 (DPLL4 x 4/(1+1)):

$$DPLL4_ALWON_FCLKOUT = DPLL4_ALWON_FCLK(266MHz) \times 4/2 = 532 \text{ MHz}$$

NOTE: The DPLL4_ALWON_FCLKOUT clock is an internal clock in DPLL4 module after the DPLL_MULT and DPLL_DIV stages. The DPLL4_M4_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1_ALWON_FCLK.

The DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit is set to 0x0 to select DSS1_ALWON_FCLK as the display subsystem functional clock:

$$DSS1_ALWON_FCLK = DPLL4_M4_CLK$$

The PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field is set to 0x08:

$$DSS1_ALWON_FCLK = \frac{DPLL4_ALWON_FCLKOUT (532MHz)}{8} = 66.5 \text{ MHz}$$

dss-E120 (19)

The DSS.DISPC_DIVISOR[23:16] LCD bit field is set to 0x01:

$$\text{LogicClock} = \frac{DSS1_ALWON_FCLK(66.5MHz)}{1} = 66.5 \text{ Mhz}$$

dss-E121 (20)

The DSS.DISPC_DIVISOR[6:0] PCD bit field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock}(66.5MHz)}{12} = 5.54 \text{ Mhz}$$

dss-E122 (21)

7.6.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

7.6.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC_DIVISOR[7:0] PCD and DSS.DISPC_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] bit field is set to 0x1 and the PCD[7:0] bit field is used as the main divider. To reduce power consumption, software users should investigate if the DSS.DISPC_DIVISOR[23:16] LCD bit field can be set to a value other than 0x1 and then decrease DSS.DISPC_DIVISOR[7:0] PCD bit field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC_DIVISOR[7:0] PCD to 0x4.

7.6.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 = 0x1
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 = 0x1
- PRCM.CM_FCLKEN_DSS[2] EN_TV = 0x1
- PRCM.CM_ICLKEN_DSS[0] EN_DSS = 0x1
- PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

7.6.2.3 DPLL4 in Low-Power Mode

For optimal power savings in low-power mode, DPLL4 can be put into low-power stop mode. Thus the DSS1_ALWON_FCLK clock cut when DPLL4 is in low-power stop mode. Software users must switch from DSS1_ALWON_FCLK to DSI1_PLL_FCLK by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x1.

NOTE: Before switching to DSI1_PLL_FCLK, the DSI PLL and the HS divider must be programmed and the DSI PLL must be locked.

DPLL4 can be put in low-power stop mode in either of the following methods:

- Manually: When setting the PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL bit to 0x1.
- Automatically: When setting the PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL bit field to 0x1. DPLL4 is automatically put in low-power stop mode when none of the 96- MHz and 54- MHz clocks are required anymore. DPLL4 is also restarted automatically.

Software users must remember to change the clock configuration after enabling DPLL4 when leaving low-power mode by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x0. The DSS1_ALWON_FCLK clock will be selected.

Lock time must be considered before disabling the DSS1_ALWON_FCLK clock.

7.6.2.4 Autoidle and Smart Idle

7.6.2.4.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

7.6.2.4.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display subsystem: DSS.DSS_SYSCONFIG[4:3] SIDLEMODE
- Display controller: DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE
- RFBI: DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE

7.6.2.5 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOWLOWTHRESHOLD
- DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO with the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

7.6.2.5.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.
- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

7.6.2.6 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. [Figure 7-152](#) shows the timings for a 240 x 320 QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

$$f_{ps} = \frac{1}{[(Hsw + 1) + (Hfp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vf p + 320 + Vbp]} \times (PCLK)$$

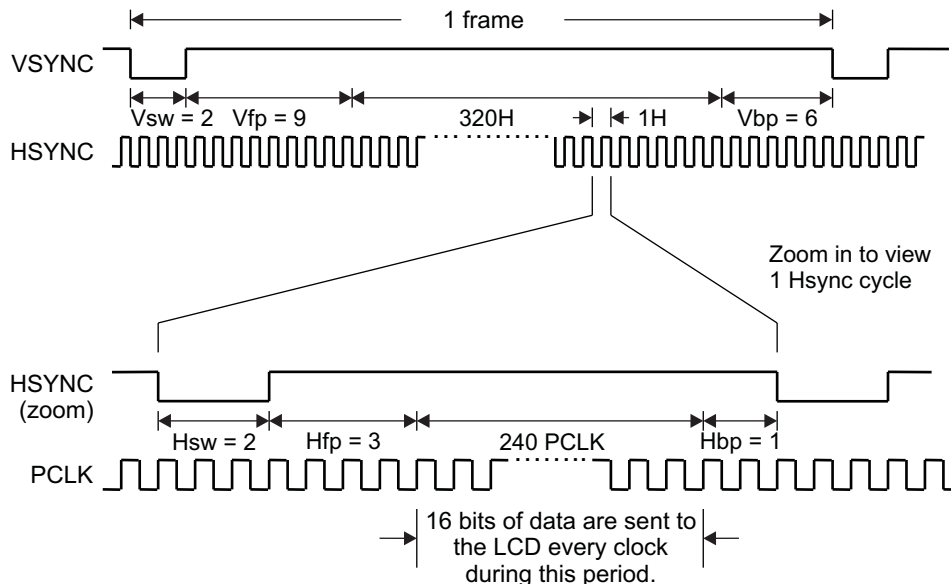

dss-E123 (22)

With:

- Hsw: DSS.DISPC_TIMING_H[7:0] HSW bit field value
- Hfp: DSS.DISPC_TIMING_H[19:8] HFP bit field value
- Hbp: DSS.DISPC_TIMING_H[31:20] HBP bit field value
- Vsw: DSS.DISPC_TIMING_V[7:0] VSW bit field value
- Vf p: DSS.DISPC_TIMING_V[19:8] VFP bit field value
- Vbp: DSS.DISPC_TIMING_V[31:20] VBP bit field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hfp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

Figure 7-152. QVGA LCD Timings

dss-124

The fps for the example of 6-MHz pixel clock with the setting shown in Figure 7-152 is as follows:

$$fps = \frac{1}{[(2 + 1) + 4 + 240 + 2] \times [(2 + 1) + 9 + 320 + 6] \times 166.67 \times 10^{-9}}$$

dss-E125

$fps = 71.57Hz$

(23)

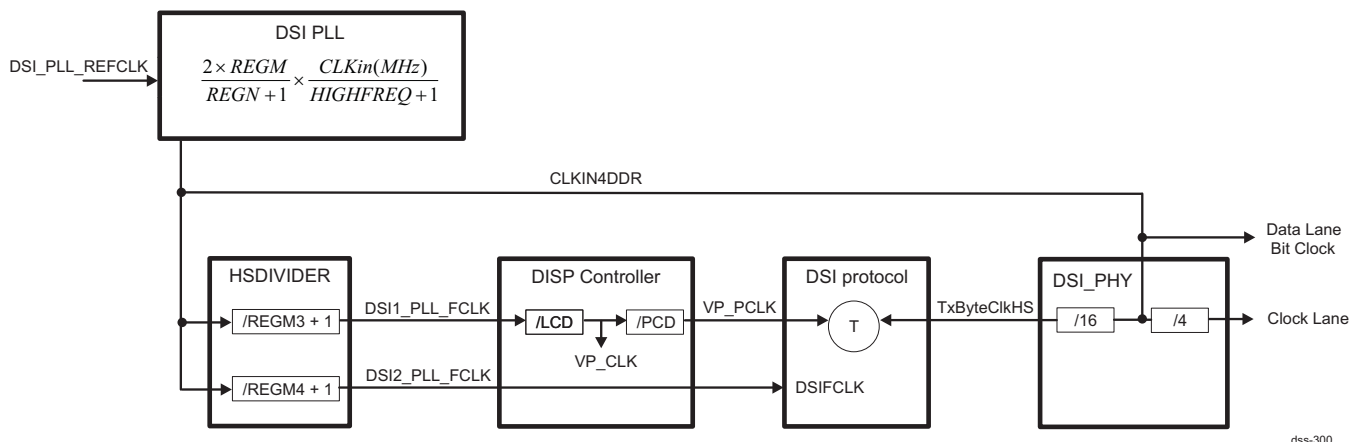

7.6.2.6.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

7.6.3 How to Configure the DSI PLL in Video Mode

Figure 7-153 shows a global overview of the DSI clock tree when used in video mode.

Figure 7-153. DSI Clock Tree in Video Mode

dss-300

The settings of the DSI PLL registers can be summarized by the following equations.

Equation 1

$$N * T_{VP_CLK} = T_L * T_{TxByteClkHS} \quad \text{dss-301} \quad (24)$$

where

$$T_L = T_{HS} + HSA_{DSI} + T_{HE} + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}$$

N is an integer

NDL: Number of data lane

WC: Word count or payload in bytes

T_{HS} and T_{HE} are equal to $4/NDL$ and 0 if they are disabled.

HSA_{DSI} is HSA period in video mode.

T_{HS} is the length of HSYNC start short packet in number of byte clock cycles (TxByteClkHS).

T_{HE} is the length of HSYNC end short packet in number of byte clock cycles (TxByteClkHS).

HBP_{DSI} is HBP period in video mode.

HFP_{DSI} is HFP period in video mode.

NOTE: HSA_{DSI} timing is not used and does not have to be programmed when HE short packet is not generated.

Equation 2

$$R = T_{TxByteClkHS} / T_{VP_PCLK} \quad \text{dss-302} \quad (25)$$

To synchronize DISPC and DSI Protocol Engine, users should follow the ratio R between TxByteClkHS and VP_PCLK as listed in [Table 7-85](#).

Table 7-85. Ratio R

Number of data lanes	Pixel format	Ratio R
1	16-bits pixel	1/2
1	18-bits pixel	4/9
1	24-bits pixel	1/3
2	16-bits pixel	1
2	18-bits pixel	8/9
2	24-bits pixel	2/3

All cases are covered by:

$$F_{VP_PCLK} * \text{bits_per_pixel} = F_{TxByteClkHS} * NDL * 8 \quad \text{dss-310}$$

Equation 3

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP_PCLK} = (4/NDL + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}) * T_{TxByteClkHS} \quad \text{dss-303} \quad (26)$$

Equation 4

$$HFP_{DSI} = ((HFP_{DISPC} * \text{bits_per_pixel}) / (NDL * 8)) - (2 / NDL) \quad \text{dss-309} \quad (27)$$

Example

The desired performances are:

- Clock lane at 150 MHz
- RGB24-888

- 1-data lane
- LCD size 480*640 with HSA_{DISP} = HFP_{DISP} = HBP_{DISP} = 20, VSA_{DISP} = VFP_{DISP} = VBP_{DISP} = 2

Step 1. Determine REGM and REGN

To obtain correct stability, Fint must be kept between 0.032 MHz and 52 MHz . In this case, Fint is maintained at 2 MHz. For more information, see the DSI PLL programming model.

$$\text{REGN} = (F_{\text{DSI_PLL_REFCLK}} / F_{\text{int}}) - 1$$

$$\text{REGN} = 12$$

$$\text{REGM} = (\text{REGN} + 1) * F_{\text{CLKIN4DDR}} / (2 * F_{\text{DSI_PLL_REFCLK}})$$

$$\text{REGM} = 150$$

dss-318

Where DSS2_ALWON_FCLK= 26 MHz is used as a reference clock for F_{DSI_PLL_REFCLK}

Step 2. Determine VP_PCLK and TxByteClkHS clocks.

TxByteClkHS frequency is equal to 37.5 MHz. With ratio R equal to 1/3, VP_PCLK frequency is equal to 12,5 MHz. The frame rate can be estimated by:

$$\text{Frame rate} = F_{\text{VP_PCLK}} / (\text{HSA}_{\text{DISPC}} + \text{HFP}_{\text{DISPC}} + \text{PPL} + \text{HBP}_{\text{DISPC}}) * (\text{VSA}_{\text{DISPC}} + \text{VFP}_{\text{DISPC}} + \text{LPP} + \text{VBP}_{\text{DISPC}})$$

$$\text{Frame rate} = 12,5 \text{ MHz} / (540) * (646)$$

$$\text{Frame rate} = 35,83 \text{ frame/sec}$$

dss-323

Step 3. Determine LCD, PCD and REGM3

$$T_{\text{CLKIN4DDR}} = T_{\text{TxByteClkHS}} / 16 = T_{\text{VP_PCLK}} / ((\text{REGM3} + 1) * \text{LCD} * \text{PCD})$$

$$((\text{REGM3} + 1) * \text{LCD} * \text{PCD}) = 16 * 3$$

dss-315

If LCD and PCD are set to 1 and 3 respectively, REGM3 is equal to 15.

Step 4. Verify N as integer

Firstly, TL must be determined

$$(\text{HSA}_{\text{DISPC}} + \text{HFP}_{\text{DISPC}} + \text{PPL} + \text{HBP}_{\text{DISPC}}) * T_{\text{VP_PCLK}} / T_{\text{TxByteClkHS}} = T_L = 1620$$

dss-316

From **Equation 1**,

$$N * T_{\text{VP_CLK}} = T_L * T_{\text{TxByteClkHS}}$$

$$N = T_{\text{TxByteClkHS}} * T_L / T_{\text{VP_CLK}} = T_L / (R * \text{PCD})$$

$$N = 14580$$

N is an integer.

Step 5. Determine HFP and HBP of the DSI protocol engine

From **Equation 3**,

$$(\text{HSA}_{\text{DISPC}} + \text{HFP}_{\text{DISPC}} + \text{PPL} + \text{HBP}_{\text{DISPC}}) * T_{\text{VP_PCLK}} / T_{\text{TxByteClkHS}} - (4/\text{NDL} + (\text{WC} + 6)/\text{NDL}) = \text{HFP}_{\text{DSI}} + \text{HBP}_{\text{DSI}}$$

$$\text{HFP}_{\text{DSI}} + \text{HBP}_{\text{DSI}} = 170$$

dss-317

From **Equation 4**,

$$\text{HFP}_{\text{DSI}} = ((\text{HFP}_{\text{DISPC}} * \text{bits_per_pixel}) / \text{NDL} * 8)) - (2 / \text{NDL})$$

$$\text{HFP}_{\text{DSI}} = 58$$

$$\text{HBP}_{\text{DSI}} = 170 - 58 = 112$$

dss-321

7.6.4 DSI Video Mode Using the DISPC Video Port

This section details the basic programming model of video mode using the DISPC video port.

The DSI interface is connected to an external MIPI display controller and the following parameters are used:

- 1 data lane: NDL = 1
- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 x 480:
 - 480 pixels per line (PPL)
 - 680 lines per panel (LPP)
- Display controller input format: YUV
- Display controller output format: RGB888, that is 24 bits per pixel (BPP)
- Word Count: WC = 3 x PPL
- DSS2_ALWON_FLCK=26 MHz is used as a reference clock for DSI PLL
- Virtual channel 0 (VC0) is used for video mode.
- Interleaving is not used.
- It is assumed that all modules used in these programming models are in after-POR state.

[Figure 7-154](#) is an overview of the connections in the display subsystem.

Figure 7-154. Overview

dss-330

The steps listed in [Table 7-86](#) are described in the following sections.

Table 7-86. Main Steps

Steps	Section
Configure DSS clocks	Section 7.6.4.1, Display Subsystem Clock Configuration
Configure the DSI and DSI PLL	Section 7.6.4.2, Configure DSI, DSI PLL and Complex I/O
Configure the external MIPI display controller	Section 7.6.4.3, Initialization of the External MIPI Display Controller
Configure the DISPC	Section 7.6.4.4, Configure the DISPC
Enable video mode using the DISPC video port	Section 7.6.4.5, Enable Video Mode Using the DISPC Video Port

The programming model must be followed in the order of the following sections.

7.6.4.1 Display Subsystem Clock Configuration

[Table 7-87](#) lists the steps required to enable the clocks.

Table 7-87. PRCM Registers

Steps	Registers	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[31:0]	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[31:0]	0x0
Automatic transition between active and inactive are disabled.	CM_CLKSTCTRL_DSS[31:0]	0x0
Enable DSS1, DSS2 and TV clock (DSS1_ALWON_FCLK, DSS2_ALWON_FCLK and TV_CLK). TV_CLK is only need for correct Reset.	CM_FCLKEN_DSS[31:0]	0x7
Enable the subsystem interface clock (DSS_L3_ICLK and DSS_L4_ICLK).	CM_ICLKEN_DSS[31:0]	0x1

7.6.4.2 Configure DSI, DSI PLL and Complex I/O

7.6.4.2.1 Reset DSI Modules

Table 7-88 lists the steps required to reset the DSI modules.

Table 7-88. Resets

Steps	Registers	Value
Reset IRQ status.	DSI_IRQSTATUS[31:0]	0x0
OCF and functional clock are maintained during wakeup, smart idle, and reset DSI.	DSI_SYSCONFIG[31:0]	0x312
Wait until RESET_DONE ≠ 0.	DSI_SYSSTATUS[0] RESET_DONE	Read 0x1

7.6.4.2.2 Set Up DSI DPLL

Table 7-89 lists the steps required to configure DSI PLL.

Table 7-89. DSI PLL Configuration Registers

Steps	Registers	Value
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CTRL	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	Read 0x2
See the calculation following this table.	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
See the calculation following this table.	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
See the calculation following this table.	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
See calculation following this table.	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Enable PLLStopMode.	DSI_PLL_CONFIGURATION1[0]	0x1
The DSI protocol engine clock divider, DSS clock divider, CLKIN4DDR, and PLL reference clock are enabled. PLL internal reference frequency is between 0.032 MHz and 52 MHz.	DSI_PLL_CONFIGURATION2[31:0]	0x5600E
Manual mode	DSI_PLL_CONTROL[31:0]	0x0
Request PLL locking sequence.	DSI_PLL_GO[0] DSI_PLL_GO	0x1
Read until DSI_PLL_GO = 0	DSI_PLL_GO[0] DSI_PLL_GO	Read 0x0
PLL is locked.	DSI_PLL_STATUS[1] DSI_PLL_LOCK	Read 0x1
Turn on PLL and HSDIVIDER; the DSI functional clock 30-MHz sync is rising/rising; the DSIStopClk signal is automatically asserted/deasserted; the L3_ICLK clock to the DSI complex I/O is not gated; and LPCLKDIVISOR = 8	DSI_CLK_CTRL[31:0]	0x8024 4008

1. Calculate the divider value for the DSI protocol engine clock source:

$$\text{RegM4} = \text{FCLKIN4DDR} / \text{DSI2_PLL_FCLK} - 1$$

$$\text{FCLKIN4DDR} = 4 \times \text{FCLKIN}$$

$$\text{RegM4} = 5$$

2. Determine LCD, PCD, and REGM3:

Calculate the divider value for DSS clock source: Same as Step 3.

$$\text{RegM3} = ((\text{BPP} \times 2) / (\text{DISPC_LCD} \times \text{DISPC_PCD} \times \text{NDL})) - 1$$

$$\text{RegM3} = 15$$

dss-E127

3. Calculate N Divider for PLL:

$$\text{FCLKIN4DDR} = \text{FCLKIN} \times 4$$

$$\text{RegN} = (\text{FDSI_PLL_REFCLK} / \text{F Int}) - 1$$

$$\text{FDSI_PLL_REFCLK} = 26 \text{ MHz (system clock)}$$

$$\text{Fint} = 2 \text{ MHz (reduce PLL lock time)}$$

$$\text{RegN} = 12$$

dss-E128

4. Calculate M divider for PLL:

$$\text{RegM} = ((\text{RegN} + 1) \times (\text{FCLKIN4DDR} / (2 \times \text{FDSI_PLL_REFCLK})))$$

$$\text{FCLKIN4DDR} = 4 \times 150 \text{ MHz}$$

$$\text{RegM} = 150$$

dss-E129

7.6.4.2.3 Switch to DSI PLL Clock Source

Select the DSI_PLL1 clock as the DISPC functional clock, and select the DSI_PLL2 clock as the DSI functional clock: Set [DSS_CONTROL](#) to 0x3.

7.6.4.2.4 Set Up DSI Protocol Engine

7.6.4.2.4.1 Set Up DSI Control Registers

[Table 7-90](#) lists the steps to set up the DSI control registers. [Table 7-91](#) lists the steps to set up the DSI complex I/O registers.

Table 7-90. DSI Control Registers

Steps	Registers	Value
Enable SYNCLOST event.	DSI_IRQENABLE [31:0]	0x4 0000
Set PACKET_SENT_IRQ_EN.	DSI_VC0_IRQENABLE [31:0]	0x4
While the HSYNC START pulse is detected, the associated short packet HSYNC START is generated.	DSI_CTRL [17] VP_HSYNC_START	0x1
While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	DSI_CTRL [15] VP_VSYNC_START	0x1
Set the trigger reset mode to <i>immediate</i> .	DSI_CTRL [14] TRIGGER_RESET_MODE	0x1
Activate two line buffers.	DSI_CTRL [13:12] LINE_BUFFER	0x2
HSYNC signal on the video port is active high.	DSI_CTRL [10] VP_HSYNC_POL	0x1
VSYNC on the video port is active high.	DSI_CTRL [11] VP_VSYNC_POL	0x1
Set the Data Enable signal on the video port as active high.	DSI_CTRL [9] VP_DE_POL	0x1
Set the size of the video port data bus for the RGB format: 0x2 for RGB 888.	DSI_CTRL [7:6] VP_DATA_BUS_WIDTH	0x2
VP_CLK_RATIO is not used if video port is used to provide data in video mode	DSI_CTRL [4] VP_CLK_RATIO	0x0

Table 7-90. DSI Control Registers (continued)

Steps	Registers	Value
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as Sequential Scheme.	DSI_CTRL[3] TX_FIFO_ARBITRATION	0x1
Enable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

Table 7-91. DSI Complex I/O Registers

Steps	Registers	Value
GOBIT, complex I/O power ON, select data, and clock position	DSI_COMPLEXIO_CFG1	0x4800 0032
Clear Reg	DSI_COMPLEXIO_IRQSTATUS	0xC3F39CE7
Disable IRQ	DSI_COMPLEXIO_IRQENABLE	0x0
Enable I/F	DSI_CTRL[0] IF_EN	0x1
Disable I/F	DSI_CTRL[0] IF_EN	0x0
Wait until IF_EN = 0	DSI_CTRL[0] IF_EN	Read 0x0
Enable Low Power clock	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Reset is done.	DSI_COMPLEXIO_CFG1[29] RESET_DONE	Read 0x1
Power control is on.	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	Read 0x1
Reset is complete.	DSI_SYSSTATUS[0] RESETDONE	Read 0x1

7.6.4.2.4.2 Configure DSI Timing and Virtual Channels

Table 7-92 lists the steps to configure DSI timing and the virtual channels.

Table 7-92. DSI Timing Registers

Steps	Registers	Value
STOP_STATE_COUNTER_IO = 0x999	DSI_TIMING1[31:0]	0x0000 0999
HS_TX_TO_X8, HS_TX_TO_COUNTER = 0x0FD2, LP_RX_TO_X16, LP_RX_TO_COUNTER = 0x00CD	DSI_TIMING2[31:0]	0x2FD2 40CD
(HSA24) (HFP12) HBP	DSI_VM_TIMING1[31:0]	0x0000 700A
(WINDOW_SYNC24) (VSA16) (DSI_VFP8) VBP	DSI_VM_TIMING2[31:0]	0x0401 0101
(TL16) DSI_VACT	DSI_VM_TIMING3[31:0]	0x05BB 0280
(ENTER_HS_MODE_LATENCY16) EXIT_HS_MODE_LATENCY	DSI_VM_TIMING7[31:0]	0x0000 C000A
DDR_CLK_PRE8 DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
HS speed, ECC generation for the Transmit, Enable CheckSum generation for the Payload.	DSI_VC0_CTRL[31:0]	0x2080 0390

- Freq TxByteClkHS:

$$FHSB = FCLKIN4DDR/16$$

$$FVPP = FCLKIN4DDR/((RegM3 + 1) \times DISPC_LCD * DISPC_PCD)$$

$$FVP = FCLKIN4DDR/(RegM3 + 1)$$

(28)

- Length of the line in video mode in Nb of byte clock cycles (TxByteClkHS):

$$TL = FHSB/FVPP \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)$$

$$TL1f = (BPP/(8 \times NDL)) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) \quad (29)$$
- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC_HSA + DISPC_HBP + PPL + DISPC_HFP) \times Fppi = (HS + HBP + ((WC + 6)/NDL) + HFP) \times Fvp$$

$$HBP + HFP = (TVPP/THSB) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP - (HS + (WC + 6)/NDL))$$

$$HBPplusHFP = (FHSB/FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + WC + 6)/NDL$$

$$HBPplusHFPf = ((FHSB/FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)) - ((HS + WC + 6)/NDL)$$

$$HFP = (DISPC_HFP \times BPP)/(NDL \times 8) - (2/NDL)$$

$$HBP = HBPplusHFP - HFP \quad (30)$$

7.6.4.2.5 Configure DSI_PHY

Calculate the timing in the functions of DDR_CLK_P (see [Table 7-93](#)). In the example, DDR_CLK_P = 1000/DSI_DDR_CLK. See [Section 7.4.3.2, Clock Requirements](#), for details on timing calculation.

Table 7-93. Calculate DSI_PHY Timing

Steps	Registers	Value
Refer to Section 7.4.3.2	DSI_PHY_REGISTER0 [31:24] REG_THSPREPARE	CEIL(70 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0 [23:16] REG_THSPRPR_THSZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0 [7:0] REG_THSEXIT	ceil(145 ns/DDR clock period)
	DSI_PHY_REGISTER0 [15:8] REG_THSTRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_REGISTER2 [7:0] REG_TCLKPREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_REGISTER1 [7:0] REG_TCLKZERO	ceil(265 ns/DDR clock period)
	DSI_PHY_REGISTER1 [15:8] REG_TCLKTRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_REGISTER1 [20:16] REG_TLPXBY2	ceil(25ns/DDR clock period)

NOTE: Keep Reserved bits at reset value in the [DSI_PHY_REGISTER1](#) and [DSI_PHY_REGISTER2](#) registers.

7.6.4.2.6 Drive Stop State

[Table 7-94](#) lists the steps to Drive Stop State.

Table 7-94. Drive Stop State

Steps	Registers	Value
Force TX stop mode	DSI_TIMING1 [15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0	DSI_TIMING1 [15] FORCE_TX_STOP_MODE_IO	Read 0x0

7.6.4.3 Initialization of the External MIPI Display Controller

1. Wait for the external MIPI display controller initialization after power up.
In this example, the external MIPI display controller is reset using GPIO 87.
2. Configure the external MIPI display controller.

7.6.4.4 Configure the DISPC

7.6.4.4.1 Reset DISPC

Table 7-95 lists the step sequence to reset the DISPC.

Table 7-95. Reset DISPC

Steps	Registers	Value
Reset the DISPC.	DISPC_SYSCONFIG[1] SOFTRESET	0x1
DISPC is reset.	DISPC_SYSCONFIG[0] RESETDONE	Read 0x1
No standby: MStandby is never asserted.	DISPC_SYSCONFIG [13:12] MIDLEMODE	0x1
Disable idle mode.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all interrupts.	DISPC_IRQENABLE[31:0]	0x0

7.6.4.4.2 Configure DISPC Timing, Window, and Color

Table 7-96 lists the steps to configure the DISPC registers. Table 7-97 lists the steps to configure the color space coefficient registers.

Table 7-98 lists the steps to configure DISPC_CONTROL.

Table 7-96. Configure DISPC Registers

Steps	Registers	Value
Set horizontal timings.	DISPC_TIMING_H	$(HBP - 120) \mid (HFP - 18) \mid HSA - 1$
Set vertical timing.	DISPC_TIMING_V	$(HBP - 120) \mid (HFP - 18) \mid HSA - 1$
Set LCD – PCD display controller and pixel clock divisor.	DISPC_DIVISOR	LDC = %1 PXLCLK = %4
Set the size of the LCD – 1.	DISPC_SIZE_LCD	$(LPP - 1 + DSI_VFP)16 \mid (PPL - 1)$
Set default RGB value when there is no data.	DISPC_DEFAULT_COLOR0	0XFF
Set video FIFO height and low threshold.	DISPC_VID1_FIFO_THRESHOLD	0xfc00c0
Set the X Y location of the upper left pixel (0 = 0) to the upper left corner.	DISPC_VID1_POSITION	0x0
Set size of the window.	DISPC_VID1_SIZE	$(LPP - 1) 16 \mid (PPL - 1)$
Set the size of the picture.	DISPC_VID1_PICTURE_SIZE	$(LPP - 1) 16 \mid (PPL - 1)$
Set the input address picture.	DISPC_VID1_BA0	0x–

Table 7-97. Configure Color Space Coefficient Registers

Comments	Registers	Value
RCR and RY coefficients	DISPC_VID1_CONV_COEF0	0X0199012A
GY and RCB coefficients	DISPC_VID1_CONV_COEF1	0X012A0000
GCB and GCR coefficients	DISPC_VID1_CONV_COEF2	0X079C0730
BCR and BY coefficients	DISPC_VID1_CONV_COEF3	0X0000012A
BCB coefficient	DISPC_VID1_CONV_COEF4	0X00000205

Table 7-98. Configure DISPC_CONTROL

Comments	Registers	Value
Enable pixel clock free-running.	DISPC_CONTROL[27] PCLKFREEENABLE	0x1
I/O pad mode selection: Bypass	DISPC_CONTROL[16] GPOUT1	0x1
I/O pad mode selection: Bypass	DISPC_CONTROL[15] GPOUT0	0x1
Normal mode selected	DISPC_CONTROL[11] STALLMODE	0x0
3 for RGB888	DISPC_CONTROL[9:8] TFTDATALINES	0x3
The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update completes.	DISPC_CONTROL[5] GOLCD	0x0
Active matrix display operation mode	DISPC_CONTROL[3] STNTFT	0x1
LCD interface is disabled.	DISPC_CONTROL[0] LCDENABLE	0x0

The input image is converted from UYVY into RGB (see [Table 7-99](#)) :

Table 7-99. Configure DISPC_VID1_ATTRIBUTES

Comments	Registers	Value
Row of VIDn will not be read twice.	DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE	0x0
8 x 32-bit bursts	DISPC_VID1_ATTRIBUTES[15:14] VIDBURSTSIZE	0x1
Full range selected: Y is not modified before the color space conversion.	DISPC_VID1_ATTRIBUTES[11] VIDFULLRANGE	0x1
Enable color space conversion CbYCr to RGB.	DISPC_VID1_ATTRIBUTES[9] VIDCOLORCONVENABLE	0x1
UYVY	DISPC_VID1_ATTRIBUTES[4:1] VIDFORMAT	0xB
Video disabled	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x0

7.6.4.5 Enable Video Mode Using the DISPC Video Port

[Table 7-100](#) lists the steps to enable DISPC to send frames continuously.

Table 7-100. Enable DISPC

Steps	Registers	Value
Set up long packet header	DSI_VC0_LONG_PACKET_HEADER[31:0]	0x0005 A03E
Enable VC0.	DSI_VC0_CTRL[1] VC_EN	0x1
Enable IF.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN ≠ 0.	DSI_CTRL[0] IF_EN	Read 0x0
Enable VID1.	DISPC_VID1_ATTRIBUTES[0] VIDENABLE	0x1
Enable LCD interface.	DISPC_CONTROL[0] LCDENABLE	0x1
Enable GOLCD.	DISPC_CONTROL[5] GOLCD	0x1
Wait until GOLCD = 0.	DISPC_CONTROL[5] GOLCD	Read 0x0

7.6.5 DSI Command Mode Using the DISPC Video Port

This section presents some generic use cases and tips for setting the modules of the display subsystem.

7.6.5.1 Display Subsystem Use Cases and Tips

This section explains the basic programming model of command mode using the DISPC video port.

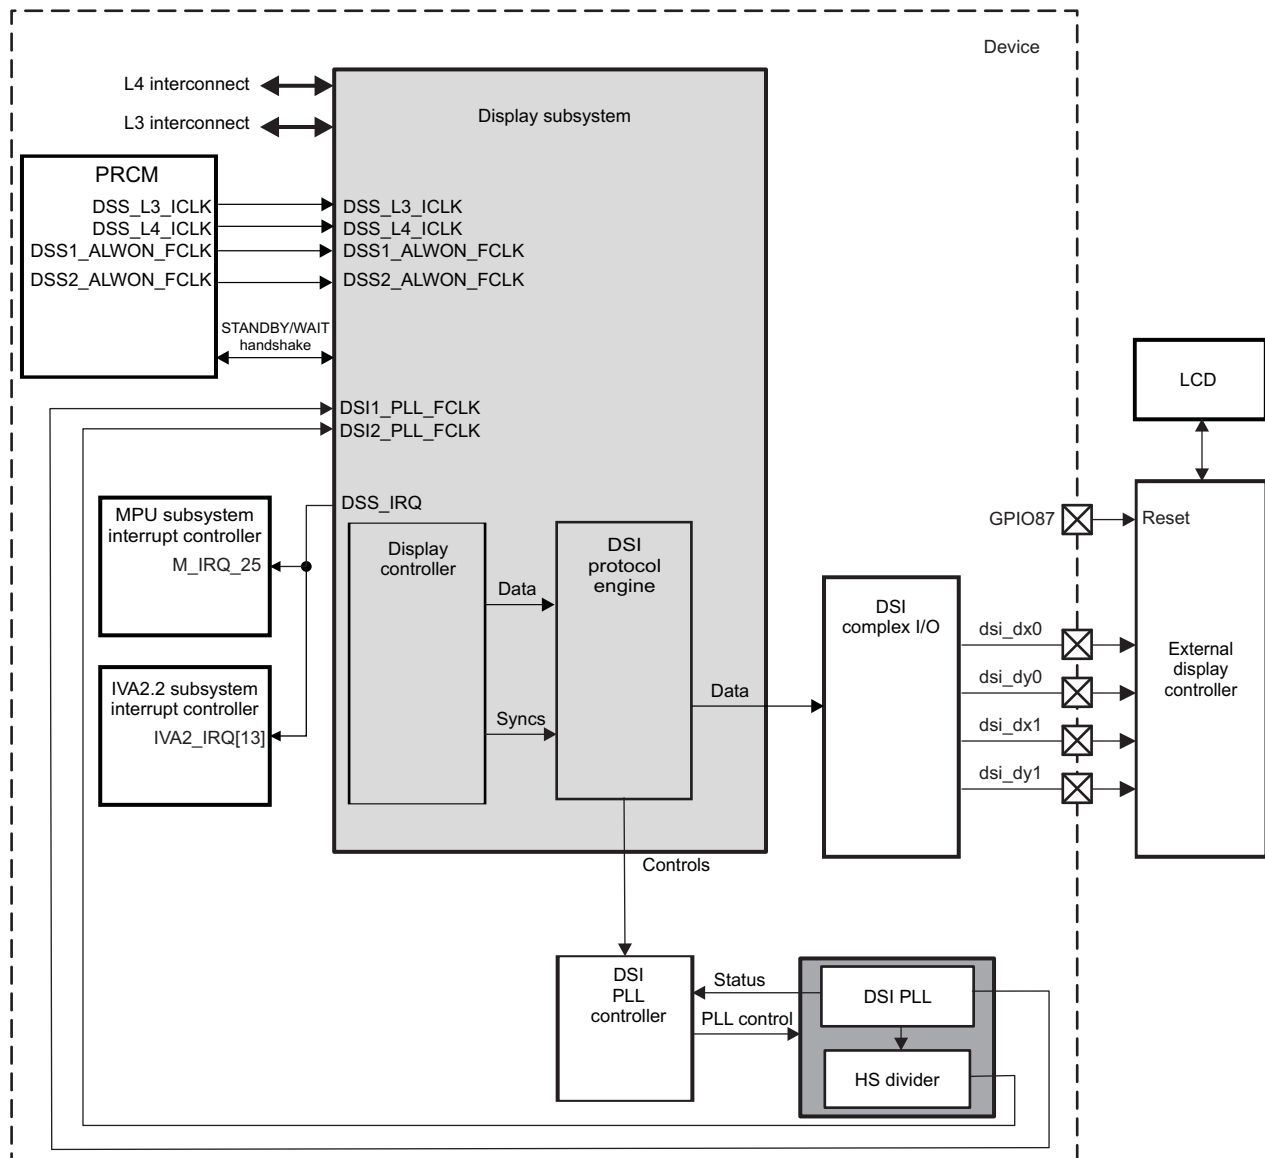

The DSI interface is connected to an external MIPI DISPC using the following parameters:

- One data lane: NDL = 1
- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 x 480:

- 480 PPL
- 680 LPP
- DISPC input format: YUV
- DISPC output format: RGB888 (24 BPP)
- Word Count: WC = 3 x PPL
- DSS2_ALWON_FCLK = 26 MHz used as a reference clock for DSI PLL
- Virtual channel 1 (VC1) used for command mode to configure the eternal DISPC, and virtual channel 0 (VC0) used to send data
- Automatic TE used for synchronization
- Interleaving not used
- It is assumed that all modules used in these programming models are in after-POR state.

Figure 7-155 is an overview of the connections in the display subsystem.

Figure 7-155. Overview

dss-330

Table 7-101 lists the steps of the main sequence and the sections that describe them.

Table 7-101. Main Sequence

Steps	Register/Bit Field/Programming Model
Configure DSS clocks.	Section 7.6.5.1.1, Configure DSS Clocks at the PRCM Module
Configure the DSI protocol engine and DSI PLL.	Section 7.6.5.1.2, Configure DSI Protocol Engine, DSI PLL, and Complex I/O
Configure the external MIPI display controller.	Section 7.6.5.1.3, Initialization of the External MIPI Display Controller
Configure the DISPC.	Section 7.6.5.1.4, Configure the DISPC
Enable command mode using the DISPC video port.	Section 7.6.5.1.5, Enable Command Mode Using the DISPC Video Port
Send a frame data to LCD panel using automatic TE.	Section 7.6.5.1.6, Send Frame Data to LCD Panel Using Automatic TE

The programming model must follow the step sequence.

7.6.5.1.1 Configure DSS Clocks at the PRCM Module

Table 7-102 lists the steps required to enable the clocks.

Table 7-102. Configure DSS Clocks at the PRCM Module

Steps	Register/Bit Field/Programming Model	Value
Set the divided DPLL value for DSS1.	CM_CLKSEL_DSS[4:0] CLKSEL_DSS1	0x9
Disable autoidle mode.	CM_AUTOIDLE_DSS[0] AUTO_DSS	0x0
Domain sleep is disabled.	CM_SLEEPDEP_DSS[2:0] EN_IVA2, EN_MPU, EN_CORE	0x0
Disable automatic transition.	CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS	0x0
Enable the DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, and TV_CLK functional clocks. ⁽¹⁾	CM_FCLKEN_DSS[2:0] EN_TV, EN_DSS2, EN_DSS1	0x7
Enable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks.	CM_ICLKEN_DSS[0] EN_DSS	0x1

⁽¹⁾ TV_CLK is required only for a correct reset.

7.6.5.1.2 Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Table 7-103 lists the steps to configure the DSI protocol engine, DSI PLL, and complex I/O and the sections that describe the sequence.

Table 7-103. Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Steps	Register/Bit Field/Programming Model
Reset DSI modules.	Section 7.6.5.1.2.1, Reset DSI Modules
Configure DSI DPLL.	Section 7.6.5.1.2.2, Configure DSI PLL
Switch to DSI PLL clock source.	Section 7.6.5.1.2.3, Switch to DSI PLL Clock Source
Configure DSI protocol engine.	Section 7.6.5.1.2.4, Configure DSI Protocol Engine
Configure DSI_PHY.	Section 7.6.5.1.2.5, Configure DSI_PHY
Drive stop state.	Section 7.6.5.1.2.6, Drive Stop State

7.6.5.1.2.1 Reset DSI Modules

Table 7-104 lists the steps required to reset the DSI modules.

Table 7-104. Reset DSI Modules

Steps	Register/Bit Field/Programming	Value
Clear DSI IRQ status.	DSI_IRQSTATUS[31:0]	0x0
Maintain interface and functional clock during wakeup.	DSI_SYSCONFIG[9:8] CLOCKACTIVITY	0x3
Enable smart-idle for power management.	DSI_SYSCONFIG[4:3] SIDLEMODE	0x2
Set DSI reset.	DSI_SYSCONFIG[1] SOFT_RESET	0x1
Wait until RESET_DONE = 1.	DSI_SYSSTATUS[0] RESET_DONE	

7.6.5.1.2.2 Configure DSI PLL

Table 7-105 lists the steps required to configure the DSI PLL.

Table 7-105. Configure DSI PLL

Steps	Register/Bit Field/Programming	Value
Enable PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2
Wait until PLL_PWR_STATUS = 0x2.	DSI_CLK_CTRL[29:28] PLL_PWR_STATUS	
Set the REGM4 value (see (1)).	DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV	5
Set the REGM3 value (see (2)).	DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV	15
Set the REGN value (see (3)).	DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN	12
Set the REGM value (see (4)).	DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM	150
Enable PLL STOPMODE.	DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE	0x1
Enable PLL reference clock control.	DSI_PLL_CONFIGURATION2[13] DSI_PLL_REFEN	0x1
Enable CLKIN4DDR control.	DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN	0x1
Enable DSS clock divider.	DSI_PLL_CONFIGURATION2[16] DSS_CLOCK_EN	0x1
Enable DSI protocol engine clock divider.	DSI_PLL_CONFIGURATION2[18] DSI_PROTO_CLOCK_EN	0x1
Enable DSI configuration update with DISPC_UPDATE_SYNC.	DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE	0x0
Start PLL locking sequence.	DSI_PLL_GO[0] DSI_PLL_GO	0x1
Wait until DSI_PLL_GO = 0.	DSI_PLL_GO[0] DSI_PLL_GO	
Check whether PLL is locked.	DSI_PLL_STATUS[1] DSI_PLL_LOCK	0x1
Set the LP mode clock ratio.	DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR	0x8
Set L3_ICLK clock to the DSI complex I/O to not gated.	DSI_CLK_CTRL[14] CIO_CLK_ICG	0x1
Enable the automatic assertion/deassertion of the DSISopClk signal.	DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE	0x1
Specify that the DSI functional clock is higher than 30 MHz with a synchronization rising/rising.	DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE	0x1
Turn on PLL and HSDIVIDER.	DSI_CLK_CTRL[31:30] PLL_PWR_CMD	0x2

- (1) Calculate the divider value for the DSI protocol engine clock source:

$$\text{RegM4} = \text{FCLKIN4DDR} / \text{FDSI_PLL_REFCLK} - 1$$

$$\text{FCLKIN4DDR} = 4 \times \text{FCLKIN}$$

$$\text{RegM4} = 5$$

dss-E126

- (2) Determine LCD, PCD, and REGM3:

Calculate the divider value for the DSS clock source: Same as Step 3.

$$\text{RegM3} = ((\text{BPP} \times 2) / (\text{DISPC_LCD} \times \text{DISPC_PCD} \times \text{NDL})) - 1$$

$$\text{RegM3} = 15$$

dss-E127

- (3) Calculate N divider for PLL:

$$\text{FCLKIN4DDR} = \text{FCLKIN} \times 4$$

$$\text{RegN} = (\text{FDSI_PLL_REFCLK} / \text{FINT}) - 1$$

$$\text{FDSI_PLL_REFCLK} = 26 \text{ MHz (system clock)}$$

$$\text{Fint} = 2 \text{ MHz (reduce PLL lock time)}$$

$$\text{RegN} = 12$$

dss-E128

(4) Calculate M divider for PLL:

$$\text{RegM} = ((\text{RegN} + 1) \times (\text{FCLKIN4DDR} / (2 \times \text{FDSI_PLL_REFCLK})))$$

$$\text{FCLKIN4DDR} = 4 \times 150 \text{ MHz}$$

$$\text{RegM} = 150$$

dss-E129

7.6.5.1.2.3 Switch to DSI PLL Clock Source

Table 7-106 lists the sequence to switch the DSI and DISPC module clocks to DSI PLL clock source.

Table 7-106. Switch to DSI PLL Clock Source

Steps	Register/Bit Field/Programming	Value
Switch DISPC clock to DSI1_PLL_FCLK.	DSS_CONTROL[0] DISPC_CLK_SWITCH	0x1
Switch DSI clock to DSI2_PLL_FCLK.	DSS_CONTROL[1] DSI_CLK_SWITCH	0x1

7.6.5.1.2.4 Configure DSI Protocol Engine

7.6.5.1.2.4.1 Set Up DSI Control Registers

Table 7-107 lists the steps required to set up the DSI control registers. Table 7-108 lists the steps to set up the DSI complex I/O registers.

Table 7-107. DSI Control Registers

Steps	Register/Bit Field/Programming	Value
Enable SYNCLOST event.	DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN	0x1
Enable IRQ to indicate that packet has been sent on VC1.	DSI_VC1_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Enable IRQ to indicate that packet has been sent on VC0.	DSI_VC0_IRQENABLE[2] PACKET_SENT_IRQ	0x1
Set the trigger reset mode to <i>immediate</i> .	DSI_CTRL[14] TRIGGER_RESET_MODE	0x1
Activate the two line buffers.	DSI_CTRL[13:12] LINE_BUFFER	0x2
Set the size of the video port data bus to 24 bits (RGB 888).	DSI_CTRL[7:6] VP_DATA_BUS_WIDTH	0x2
Define the ratio between VP_CLK and VP_PCLK.	DSI_CTRL[4] VP_CLK_RATIO	0x1
Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as sequential scheme.	DSI_CTRL[3] TX_FIFO_ARBITRATION	0x1
Enable the ECC check for the received header.	DSI_CTRL[2] ECC_RX_EN	0x1

Table 7-108. DSI Complex I/O Registers

Steps	Register/Bit Field/Programming	Value
Determine the position of the clock lane.	DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION	0x2
Determine the position of data 1 lane.	DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION	0x3
Turn on COMPLEXIO.	DSI_COMPLEXIO_CFG1[28:27] PWR_CMD	0x1

Table 7-108. DSI Complex I/O Registers (continued)

Steps	Register/Bit Field/Programming	Value
Enable the synchronization of the shadow registers with DISPC_UPDATE_SYNC.	DSI_COMPLEXIO_CFG1[30] GOBIT	0x1
Clear all COMPLEXIO IRQ status.	DSI_COMPLEXIO_IRQSTATUS	0xC3F39CE7
Disable all COMPLEXIO IRQs.	DSI_COMPLEXIO_IRQENABLE	0x0
Enable interface.	DSI_CTRL[0] IF_EN	0x1
Disable interface.	DSI_CTRL[0] IF_EN	0x0
Wait until IF_EN = 0.	DSI_CTRL[0] IF_EN	
Enable the LP clock.	DSI_CLK_CTRL[20] LP_CLK_ENABLE	0x1
Check whether reset is complete.	DSI_COMPLEXIO_CFG1[29] RESET_DONE	0x1
Check whether power control is on.	DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS	0x1
Check whether reset is complete.	DSI_SYSSTATUS[0] RESETDONE	0x1

7.6.5.1.2.4.2 Configure DSI Timing and Virtual Channels

Table 7-109 lists the steps to configure DSI timing and the virtual channels.

Table 7-109. DSI Timing Registers

Steps	Register/Bit Field/Programming	Value
Determine the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO	0x999
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[13] STOP_STATE_X4_IO	0x0
Disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the STOP-STATE counter.	DSI_TIMING1[14] STOP_STATE_X16_IO	0x0
Clear turn-around timer settings.	DSI_TIMING1[30:16]	0x0000
Determine the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[12:0] LP_RX_TO_COUNTER	0x0CD
Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[13] LP_RX_TO_X4	0x0
Enable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the LP RX timer.	DSI_TIMING2[14] LP_RX_TO_X16	0x1
Determine the number of TxByteClkHS clock cycles for the HS RX timer.	DSI_TIMING2[12:0] HS_TX_TO_COUNTER	0xFD2
Disable the multiplication factor of 8 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[13] HS_TX_TO_X8	0x0
Enable the multiplication factor of 16 for the number of TxByteClkHS clock cycles for the HS TX timer.	DSI_TIMING2[14] HS_TX_TO_X16	0x1
DDR_CLK_PRE8 DDR_CLK_POST	DSI_CLK_TIMING[31:0]	0x0000 0F0B
Configuration of VC1		
Enable the checksum generation for the transmit payload.	DSI_VC1_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC1_CTRL[8] ECC_TX_EN	0x1
Disable DMA request for TX FIFO.	DSI_VC1_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC1_CTRL[29:27] DMA_RX_REQ_NB	0x4
Configuration of VC0		
Selects source of data and enable VP_STALL.	DSI_VC0_CTRL[1] SOURCE	0x1

Table 7-109. DSI Timing Registers (continued)

Steps	Register/Bit Field/Programming	Value
Enable the checksum generation for the transmit payload.	DSI_VC0_CTRL[7] CS_TX_EN	0x1
Enable the ECC generation for the transmit header.	DSI_VC0_CTRL[8] ECC_TX_EN	0x1
Enable high-speed mode to send short and long packets to the peripheral.	DSI_VC0_CTRL[9] MODE_SPEED	0x1
Disable DMA request for TX FIFO.	DSI_VC0_CTRL[23:21] DMA_TX_REQ_NB	0x4
Disable DMA request for RX FIFO.	DSI_VC0_CTRL[29:27] DMA_RX_REQ_NB	0x4
Configuration TX and RX FIFO		
Set size of the RX FIFO allocated for VC1 to 32 x 33 bits.	DSI_RX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x1
Set size of the TX and TX FIFO allocated for VC1 to 96 x 33 bits.	DSI_TX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE	0x3

- Freq TxByteClkHS:

$$FHSB = FCLKIN4DDR / 16$$

$$FVPP = FCLKIN4DDR / ((RegM3 + 1) \times DISPC_LCD * DISPC_PCD)$$

$$FVP = FCLKIN4DDR / (RegM3 + 1)$$

dss-E130
- Length of the line in video mode in number of byte clock cycles (TxByteClkHS):

$$TL = FHSB / FVPP \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)$$

$$TL1f = (BPP / (8 \times NDL)) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)$$

dss-E131
- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC_HSA + DISPC_HBP + PPL + DISPC_HFP) \times Fppi = (HS + HBP + ((WC + 6) / NDL) + HFP) \times Fvp$$

$$HBP + HFP = (TVPP / THSB) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + (WC + 6) / NDL)$$

$$HBPplusHFP = (FHSB / FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + WC + 6) / NDL$$

$$HBPplusHFPf = ((FHSB / FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)) - ((HS + WC + 6) / NDL)$$

$$HFP = (DISPC_HFP \times BPP) / (NDL \times 8) - (2 / NDL)$$

$$HBP = HBPplusHFP - HFP$$

dss-E132

7.6.5.1.2.5 Configure DSI_PHY Timing

Table 7-110 summarizes DSI_PHY timing in the functions of DDR_CLK_P with DDR_CLK_P = 1000/DSI_DDR_CLK. For more details on timing calculation, see [Section 7.4.3.2, Clock Requirements](#).

Table 7-110. Configure DSI_PHY Timing

Steps	Register/Bit Field/Programming	Value
Settings of the DSI protocol timing. For a complete description of timing specifications, see Section 7.4.3.2, Clock Requirements .	DSI_PHY_REGISTER0[31:24] REG_THSPREPARE	CEIL(70 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[23:16] REG_THSPRPR_THSZERO	ceil(175 ns/DDR clock period) + 2
	DSI_PHY_REGISTER0[7:0] REG_THSEXIT	ceil(145 ns/DDR clock period)

Table 7-110. Configure DSI_PHY Timing (continued)

Steps	Register/Bit Field/Programming	Value
	DSI_PHY_REGISTER0 [15:8] REG_THSTRAIL	ceil(60 ns/DDR clock period) + 5
	DSI_PHY_REGISTER2 [7:0] REG_TCLKPREPARE	ceil(65 ns/DDR clock period)
	DSI_PHY_REGISTER1 [7:0] REG_TCLKZERO	ceil(265 ns/DDR clock period)
	DSI_PHY_REGISTER1 [15:8] REG_TCLKTRAIL	ceil(60 ns/DDR clock period) + 2
	DSI_PHY_REGISTER1 [20:16] REG_TLPXBY2	ceil(25ns/DDR clock period)

NOTE: Keep Reserved bits at reset value in the [DSI_PHY_REGISTER1](#) and [DSI_PHY_REGISTER2](#) registers.

7.6.5.1.2.6 Drive Stop State

[Table 7-111](#) lists the steps to drive the stop state.

Table 7-111. Drive Stop State

Steps	Register/Bit Field/Programming	Value
Force TX stop mode.	DSI_TIMING1 [15] FORCE_TX_STOP_MODE_IO	0x1
Wait until FORCE_TX_STOP_MODE_IO = 0.	DSI_TIMING1 [15] FORCE_TX_STOP_MODE_IO	

7.6.5.1.3 Initialization of the External MIPI LCD Controller

[Table 7-112](#) lists the steps to initialize the external MIPI LCD controller.

Table 7-112. Initialization of the External MIPI LCD Controller

Steps	Register/Bit Field/Programming	Value
Reset the MIPI LCD controller using GPIO87.	–	0x1
Wait until initialization of the external MIPI LCD controller is finished after power up.	–	–
Configure the external MIPI LCD controller.	–	–

7.6.5.1.4 Configure the DISPC

7.6.5.1.4.1 Reset DISPC

[Table 7-113](#) lists the steps to reset the DISPC.

Table 7-113. Reset DISPC

Steps	Register/Bit Field/Programming	Value
Reset the DISPC.	DISPC_SYSCONFIG [1] SOFTRESET	0x1
Wait until RESETDONE = 1.	DISPC_SYSCONFIG [0] RESETDONE	
Disable master interface power management.	DISPC_SYSCONFIG [13:12] MIDDLEMODE	0x1
Disable slave interface power management.	DISPC_SYSCONFIG [4:3] SIDLEMODE	0x1
Disable all DISPC interrupts.	DISPC_IRQENABLE [31:0]	0x0

7.6.5.1.4.2 Configure DISPC Timing, Window, and Color

Table 7-114 lists the steps to configure the DISPC registers. Table 7-97 lists the steps to configure the color space coefficient registers.

Table 7-115 lists the steps to configure DISPC_CONTROL.

Table 7-114. Configure DISPC Registers

Steps	Register/Bit Field/Programming	Value
Configure LCD output		
Set the logic clock divisor (LCD).	DISPC_DIVISOR[23:16] LCD	0x1
Set the pixel clock divisor (PCD).	DISPC_DIVISOR[7:0] PCD	0x4
Set the number of lines on the LCD panel.	DISPC_SIZE_LCD[26:16] LPP	0x2A7
Set the number of PPL on the LCD panel.	DISPC_SIZE_LCD[10:0] PPL	0x1DF
Set solid background color.	DISPC_DEFAULT_COLOR0	0xFF
Configure VIDEO pipeline VID1.		
Set VID1 FIFO low threshold.	DISPC_VID1_FIFO_THRESHOLD[11:0] VIDFIFOWHRESHOLD	0x0C0
Set VID1 FIFO high threshold.	DISPC_VID1_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD	0xFC0
Set the X position of the VID1 window.	DISPC_VID1_POSITION[10:0] VIDPOX	0x0
Set the Y position of the VID1 window.	DISPC_VID1_POSITION[26:16] VIDPOSY	0x0
Set the number of lines of the VID1 window.	DISPC_VID1_SIZE[26:16] VIDSIZEY	0x2A7
Set the number of pixels of the VID1 window.	DISPC_VID1_SIZE[10:0] VIDSIZEX	0x1DF
Define the base address of the VID1 frame buffer.	DISPC_VID1_BA0	0x–

Table 7-115. Configure DISPC_CONTROL

Comments	Register/Bit Field/Programming	Value
Enable pixel clock free-running.	DISPC_CONTROL[27] PCLKFREEENABLE	0x1
Disable RFBI.	DISPC_CONTROL[16] GPOUT1	0x1
	DISPC_CONTROL[15] GPOUT0	0x1
Enable the stall mode.	DISPC_CONTROL[11] STALLMODE	0x1
Select size of DATALINES.	DISPC_CONTROL[9:8] TFTDATALINES	0x3
Select active matrix display operation mode.	DISPC_CONTROL[3] STNTFT	0x1
Disable LCD output interface.	DISPC_CONTROL[0] LCDENABLE	0x0
Update the internal DISPC registers.	DISPC_CONTROL[5] GOLCD	0x1

7.6.5.1.5 Enable Command Mode Using DISPC Video Port

Table 7-116 lists the steps to enable DISPC to send frames continuously. Two bus turnarounds (BTA) must be generated:

- The first BTA gives bus possession to the display module.
- The second BTA obtains the TE trigger.

Table 7-116. Enable Command Mode and Automatic TE

Steps	Register/Bit Field/Programming	Value
Insert DCS write memory continue code.	DSI_CTRL[25] DCS_CMD_CODE	0x0
Enable automatic insertion of DCS command codes when data is sourced by the video port.	DSI_CTRL[24] DCS_CMD_ENABLE	0x1
Enable VC1.	DSI_VC1_CTRL[0] VC_EN	0x1

Table 7-116. Enable Command Mode and Automatic TE (continued)

Steps	Register/Bit Field/Programming	Value
Enable VC0.	DSI_VC0_CTRL[0] VC_EN	0x1
Enable the interface.	DSI_CTRL[0] IF_EN	0x1
Wait until IF_EN = 1.	DSI_CTRL[0] IF_EN	
Send the sequence to receive the TE trigger from the peripheral. In this use case, code 0x35 + 1 parameter VC = 0, data type = 0x15, DCS write + 1 parameter.	DSI_VC1_SHORT_PACKET_HEADER[31:0] HEADER	0x0000 3515
Wait until PACKET_SENT_IRQ = 1.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	
Write 1 to clear PACKET_SENT_IRQ.	DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ	0x1

7.6.5.1.6 Send Frame Data to LCD Panel Using Automatic TE

Table 7-117 summarizes the steps to send a frame data to the LCD panel using automatic TE.

Table 7-117. Send Frame Data to LCD Panel Using Automatic TE

Steps	Register/Bit Field/Programming	Value
Enable the transfer between DISPC and DSI. Reset after the transfer is done.	DISPC_CONTROL[0] LCDENABLE	0x1
Specify the number of bytes to send. When DCS insertions is used, word count (WC) must include this one DCS byte.	DSI_VC0_TE[23:0] TE_SIZE	(WC+1)*LPP
Set up long packet header. Send 0x39 DCS long write/write_LUT command packet used to send larger blocks of data to a display module that implements a DCS.	DSI_VC0_LONG_PACKET_HEADER[31:0] HEADER	(WC+1) 8 + 0x39
Enable TE control.	DSI_VC0_TE[30] TE_EN	0x1
Wait until RX FIFO is empty, RX_FIFO_NOT_EMPTY = 0.	DSI_VC1_CTRL[20] RX_FIFO_NOT_EMPTY	0x0
Wait until TX FIFO is not full. TX_FIFO_FULL = 0.	DSI_VC1_CTRL[16] TX_FIFO_FULL	0x0
Enable first BTA to give bus possession to the display module.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Enable second BTA to get the TE trigger.	DSI_VC1_CTRL[6] BTA_EN	0x1
Wait until BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Write 1 to clear BTA IRQ.	DSI_VC1_IRQSTATUS[5] BTA_IRQ	0x1
Wait until transfer is complete.	DSI_VC0_TE[30] TE_EN	Read 0x0

7.7 Display Subsystem Register Manual

CAUTION

- The DISS, DISPC, RFBI, and VENC registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.
- The DSI complex I/O and DSI PLL control module registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine [DSS.DSI_VCn_LONG_PACKET_HEADER](#) and [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine [DSS.DSI_VCn_LONG_PACKET_PAYLOAD](#) register is limited to 32-bit and 16-bit data access; 8-bit data accesses are not allowed and can corrupt register content.
- All other DSI protocol engine registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.

[Table 7-118](#) summarizes the display subsystem instance.

Table 7-118. Display Subsystem Instance Summary

Module Name	Base Address	Size
DSI Protocol Engine	0x4804 FC00	512 bytes
DSI_PHY	0x4804 FE00	64 bytes
DSI PLL Controller	0x4804 FF00	32 bytes
Display Subsystem	0x4805 0000	512 bytes
Display Controller	0x4805 0400	1KB
Display Controller VID1	0x4805 0400	1KB
Display Controller VID2	0x4805 0400	1KB
RFBI	0x4805 0800	256 bytes
Video Encoder	0x4805 0C00	256 bytes

Bits	Field Name	Description	Type	Reset
31:30	SPATIALTEMPORAL DITHERINGFRAMES	Spatial/Temporal dithering number of frames wr: VFP 0x0: Spatial only 0x1: Spatial and temporal over two frames 0x2: Spatial and temporal over four frames 0x3: Reserved	RW	0x0
29	LCDENABLEPOL	LCD Enable Signal Polarity 0x0: Active low 0x1: Active high	RW	0
28	LCDENABLESIGNAL	LCD Enable Signal: LCD interface active/inactive 0x0: Signal disabled 0x1: Signal enabled	RW	0
27	PCKFREEENABLE	Pixel clock free-running enabled/disabled 0x0: Clock disabled 0x1: Clock enabled	RW	0
26:25	TDMUNUSEDBITS	State of unused bits (TDM mode only) WR: VFP 0x0: Low level (0) 0x1: High level (1) 0x2: Unchanged from previous state 0x3: Reserved	RW	0x0
24:23	TDMCYCLEFORMAT	Cycle format (TDM mode only) WR: VFP 0x0: 1 cycle for 1 pixel 0x1: 2 cycles for 1 pixel 0x2: 3 cycles for 1 pixel 0x3: 3 cycles for 2 pixels	RW	0x0
22:21	TDMPARALLELMODE	Output Interface width (TDM mode only) WR: VFP 0x0: 8-bit parallel output interface selected 0x1: 9-bit parallel output interface selected 0x2: 12-bit parallel output interface selected 0x3: 16-bit parallel output interface selected	RW	0x0
20	TDMENABLE	Enable the multiple cycle format (TDM mode used only for Active Matrix mode with the RFBI enable bit off). WR: VFP 0x0: TDM disabled	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: TDM enabled		
19:17	HT	Hold Time for digital output WR: EVSYNC Encoded value (from 0 to 7) holds time for digital output. The data will be held for (HT + 1) external digital clock periods.	RW	0x0
16	GPOUT1	General Purpose Output Signal 0x0: The GPout1 is reset. 0x1: The GPout1 is set.	RW	0
15	GPOUT0	General Purpose Output Signal 0x0: The GPout0 is reset. 0x1: The GPout0 is set.	RW	0
14	GPIN1	General Purpose Input Signal WR: VFP Read 0x0: The GPin1 has been reset. Read 0x1: The GPin1 has been set.	R	0
13	GPIN0	General Purpose Input Signal WR: VFP Read 0x0: The GPin0 has been reset. Read 0x1: The GPin0 has been set.	R	0
12	OVERLAYOPTIMIZATION	Overlay Optimization (available when graphics format is NOT is 1-, 2, and 4-BPP) WR: VFP or EVSYNC 0x0: Graphics data below video1 window fetched from memory or no overlap between graphics and video1 windows. 0x1: Graphics data below video1 window not fetched from memory.	RW	0
11	STALLMODE	Stall mode for the LCD output wr: VFP 0x0: Normal mode selected 0x1: Stall mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame. The stall mode is used in RFBI and DSI command modes.	RW	0
10	Reserved	Reserved for non-GP devices	RW	0
9:8	TFTDATALINES	Number of lines of the LCD interface WR: VFP 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface	RW	0x0
7	STDITHERENABLE	Spatial temporal dithering enable WR: VFP 0x0: Spatial/temporal dithering logic disabled 0x1: Spatial/temporal dithering logic enabled	RW	0
6	GODIGITAL	Digital GO Command	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the digital output using the user values. The hardware resets the bit when the update is completed.		
		0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the digital output and the hardware can update the internal registers at the external VSYNC.		
5	GOLCD	LCD GO Command	RW	0
		0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed.		
		0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period.		
4	M8B	Mono 8-bit mode WR: VFP	RW	0
		0x0: Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition (only in Passive Mono 8-bit mode).		
		0x1: Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition (only in Passive Mono 8-bit mode).		
3	STNTFT	LCD display type WR: VFP	RW	0
		0x0: Passive or Passive Matrix display operation enabled. Passive Matrix dither logic enabled.		
		0x1: Active Matrix display operation enabled. Passive Matrix Dither logic and output FIFO bypassed.		
2	MONOCOLOR	Monochrome/Color WR: VFP	RW	0
		0x0: Color operation enabled (Passive Matrix mode only)		
		0x1: Monochrome operation enabled (Passive Matrix mode only)		
1	DIGITALENABLE	Digital enable	RW	0
		0x0: Digital output disabled (at the end of the current field if interlace output when the bit is reset)		
		0x1: Digital output enabled		
0	LCDENABLE	LCD enable	RW	0
		0x0: LCD output disabled (at the end of the frame when the bit is reset)		
		0x1: LCD output enabled

- [Command Mode: \[10\]](#)

Bits	Field Name	Description	Type	Reset
31: 20	Reserved	Write 0s for future compatibility. Read returns 0	RW	0x00000
19	TVALPHABLENDER ENABLE	Selects the alpha blender (TV output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
18	LCDALPHABLENDER ENABLE	Selects the alpha blender (LCD output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled.	RW	0
17	FIFOFILLING	Controls if the FIFO are refilled only when the LOW threshold is reached or if all FIFO are refilled when at least one of them reaches the LOW threshold. 0x0: Each FIFO is refilled when it reaches LOW threshold. 0x1: All FIFOs are refilled up to high threshold when at least one of them reaches the LOW threshold. (only active FIFOs should be considered and when reaching the end of the frame the FIFO goes to empty condition so no need to fill it again).	RW	0
16	FIFOHANDCHECK	Controls the handshake between FIFO and RFBI STALL to prevent from underflow. The bit should be set to 0 when the module is not in STALL mode. 0x0: Only the STALL signal from RFBI is used regardless of the FIFO fullness information to provide data to the RFBI module. 0x1: The STALL signal from RFBI is used in combination with the FIFO fullness information to provide data to the RFBI module only when it does not generated FIFO underflow.	RW	0
15	CPR	Color phase rotation control wr: VFP 0x0: Color phase rotation disabled 0x1: Color phase rotation enabled	RW	0
14	FIFOMERGE	FIFO merge control wr: EVSYNC or VFP 0x0: FIFO merge disabled Each FIFO is dedicated to one pipeline. 0x1: FIFO merge enabled All the FIFOS are merged into a single one to be used by the single active pipeline.	RW	0
13	TCKDIGSELECTION	Transparency color key selection (digital output) wr: EVSYNC 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode	RW	0
12	TCKDIGENABLE	Transparency color key enabled (digital output) wr: EVSYNC 0x0: Disable the transparency color key for digital output 0x1: Enable the transparency color key for digital output	RW	0
11	TCKLCDSELECTION	Transparency color key selection (LCD output) WR: VFP 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode	RW	0
10	TCKLCDENABLE	Transparency color key enabled (LCD output) WR: VFP *	RW	0

Bits	Field Name	Description	Type	Reset
		0x0: Disable the transparency color key for the LCD 0x1: Enable the transparency color key for the LCD		
9	FUNCGATED	Functional clocks gated enabled WR: immediate 0x0: Functional clocks gated disabled 0x1: Functional clocks gated enabled	RW	0
8	ACBIASGATED	ACBias Gated Enabled WR: VFP 0x0: ACBias Gated Disabled 0x1: ACBias Gated Enabled	RW	0
7	VSYNCGATED	VSYNC Gated Enabled WR: VFP 0x0: VSYNC Gated Disabled 0x1: VSYNC Gated Enabled	RW	0
6	HSYNCGATED	HSYNC Gated Enabled WR: VFP 0x0: HSYNC Gated Disabled 0x1: HSYNC Gated Enabled	RW	0
5	PIXELCLOCKGATED	Pixel Clock Gated Enabled WR: VFP 0x0: Pixel Clock Gated Disabled 0x1: Pixel Clock Gated Enabled	RW	0
4	PIXELDATAGATED	Pixel Data Gated Enabled WR: VFP 0x0: Pixel Data Gated Disabled 0x1: Pixel Data Gated Enabled	RW	0
3	PALETTEGAMMATABL	Palette/Gamma Table selection WR: EVSYNC or VFP 0x0: LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 0x1: LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present)	RW	0
2:1	LOADMODE	Loading Mode for the Palette/Gamma Table WR: EVSYNC or VFP 0x0: Palette/Gamma Table and data are loaded every frame. 0x1: Palette/Gamma Table to be loaded. Users set the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. (DISPC_GFX_ATTRIBUTES . GfxEnable has to be set to 1). 0x2: Frame data only loaded every frame 0x3: Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W).	RW	0x0
0	PIXELGATED	Pixel Gated Enable (only for Active Matrix Display) WR: VFP 0x0: Pixel clock always toggles (only in Active Matrix mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode)	RW	0

Description	The register configures the attributes of video window #n such as format, resizeenable, shadow register, updated on VFP start period, or EVSYNC.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
RESERVED				PREMULTIPLYALPHA				RESERVED				VIDSELFREFRESH	VIDARBTRATION	VIDLINEBUFFERSPLIT	VIDVERTICALTAPS	VIDDMAOPTIMIZATION	VIDFIFOPRELOAD	VIDROWREPEATENABLE	VIDENDIANNESS	VIDCHANNELOUT	VIDBURSTSIZE	VIDROTATION	VIDFULLRANGE	VIDREPLICATIONENABLE	VIDCOLORCONVENABLE	VIDRESIZECONF	VIDHRESIZECONF	VIDRESIZEENABLE	VIDFORMAT				VIDENABLE

Bits	Field Name	Description	Type	Reset
31: 29	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000
28	PREMULTIPLYALPHA	The field configures the DISPC VID2 to process incoming data as pre-multiplied alpha data or non pre-multiplied alpha data. Default setting is non pre-multiplied alpha data. 0x0: Non pre-multiplyalpha data color component 0x1: Premultiplyalpha data color component	RW	0
<hr/> <p>NOTE: The pre-multiplied alpha control is supported only on VID2. For VID1 this bitfield is RESERVED. The pre-multiplied alpha option is only valid when bit field [4:1] VIDFORMAT is set to ARGB or RGBA formats. Otherwise, the PREMULTIPLYALPHA bit field is ignored by the hardware.</p> <hr/>				
27: 25	RESERVED	Write 0s for future compatibility. Read returns 0.	RW	0x0000
24	VIDSELFREFRESH	Enables the self refresh of the video window from its own FIFO only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory 0x1: The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO	RW	0
23	VIDARBITRATION	Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline.	RW	0
22	VIDLINEBUFFER SPLIT	Video vertical line buffer split 0x0: Vertical line buffers are not split. 0x1: Vertical line buffers are split into two.	RW	0
21	VIDVERTICALTAPS	Video vertical resize tap number 0x0: Three taps are used for the vertical filtering logic. The other two taps are not used. 0x1: Five taps are used for the vertical filtering logic.	RW	0
20	VIDDMAOPTI MIZATION	Video optimization in case of 0x0: The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). 0x1: The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). The bit field [21] VIDVERTICALTAPS shall be set to 0x1, bit field [22] VIDLINEBUFFERSPLIT to 0x1, and all scaler registers shall be configured even for 1:1 ratio. Even width is required for the input picture when 5 taps are used.	RW	0
19	VIDFIFOPRELOAD	Video preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register.	RW	0

Bits	Field Name	Description	Type	Reset
		0x1: H/W prefetches pixels up to the high threshold value.		
18	VIDROWREPEAT ENABLE	Video Row Repeat (YUV case only when rotating 90 or 270-degree) 0x0: Row of VIDn won't be read twice. 0x1: The Row data are fetched twice to extract both the Y components	RW	0
17	VIDENDIANNESS	Video Endianness 0x0: Little endian operation is selected. 0x1: Big endian operation is selected.	RW	0
16	VIDCHANNELOUT	Video Channel Out configuration wr: Immediate 0x0: LCD output selected 0x1: 24 bit output selected	RW	0
15:14	VIDBURSTSIZE	Video DMA Burst Size 0x0: 4x32bit bursts 0x1: 8x32bit bursts 0x2: 16x32bit bursts 0x3: Reserved	RW	0x0
13:12	VIDROTATION	Video Rotation Flag 0x0: No rotation or VidFormat is RGB 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees 0x3: Rotation by 270 degrees	RW	0x0
11	VIDFULLRANGE	VidFullRange 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion	RW	0
10	VIDREPLICATION ENABLE	VidReplicationEnable 0x0: Disable Video replication logic 0x1: Enable Video replication logic	RW	0
9	VIDCOLORCONV ENABLE	VidColorConvEnable 0x0: Disable Color Space Conversion CbYCr to RGB 0x1: Enable Color Space Conversion CbYCr to RGB	RW	0
8	VIDVRESIZECONF	Video Vertical Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected	RW	0
7	VIDHRESIZECONF	Video Horizontal Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected	RW	0
6:5	VIDRESIZEENABLE	Video Resize Enable 0x0: Disable the resize processing 0x1: Enable the horizontal resize processing 0x2: Enable the vertical resize processing 0x3: Enable both horizontal and vertical resize processing	RW	0x0
4:1	VIDFORMAT (Video 1 channel)	Video1 channel Format; Other enums: Reserved (all other values between 0x0 and 0x3, 0x5, 0x7, and between 0xC and 0xF) 0x4: RGB12 (16-bit container) 0x6: RGB 16 0x8: RGB 24 (unpacked in 32-bit container)	RW	0x0

Bits	Field Name	Description	Type	Reset

Table 7-252. RFBI_CONTROL

Address Offset	0x40	Instance	RFBI
Physical address	0x4805 0840		
Description	The control register allows configuration of the RFBI module.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																SMART_DMA_REQ	DISABLE_DMA_REQ	HIGHTHRESHOLD	ITE	CONFIGSELECT	BYPASSMODE	ENABLE									

Bits	Field Name	Description	Type	Reset
31: 9	Reserved	Write 0s for future compatibility Read returns 0	RW	0x0000000
8	SMART_DMA_REQ	Smart DMA request 0x0: The dmareq is asserted and de-asserted depending on the interconnect FIFO space even if Mldlreq is high in smart idle/no-idle mode and the entire burst gets error responses from the module. 0x1: The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and Mldlreq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the interconnect FIFO.	RW	0x0
7	DISABLE_DMA_REQ	Disable DMA request 0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register. 0x1: The dmareq is disabled and the signal is not generated at all based on space in the interconnect FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in the interconnect FIFO to take requests.	RW	0x0
6:5	HIGHTHRESHOLD	Defines the interconnect FIFO high threshold used by HW to assert DMA request. Used only if data written to RFBI_DATA are sent using system DMA. 0x0: Size of the transfer of 4 words of 32-bit wide 0x1: Size of the transfer of 8 words of 32-bit wide 0x2: Size of the transfer of 16 words of 32-bit wide	RW	0x0
4	ITE	Internal Trigger 0: H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use. 1: User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it.	RW	0
3:2	CONFIGSELECT	Select the CS and configuration 00: No CS selected 01: CS0 selected and configuration #0 10: CS1 selected and configuration #1 11: CS0 and CS1 both selected (only the configuration for CS0 is used)	RW	0x0
1	BYPASSMODE	Bypass Mode 0: The bypass mode not selected 1: The bypass mode is selected	RW	1
0	ENABLE	Enable/Disable flag 0: Disable the RFBI module 1: Enable the RFBI module	RW	0

Description	VENC LAL and PHASE_RESET		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												PRES	SBLANK	Reserved								LAL									

Bits	Field Name	Description	Type	Reset
31:19	Reserved	Reserved. Read returns 0s.	RW	0x0000
18:17	PRES	Phase reset mode. 0x0: No reset 0x1: Reset every two lines 0x2: Reset every eight fields. Color subcarrier phase is reset to VENC_CPHASE[7:0] CPHS field value (offset 0x2C) upon reset 0x3: Reset every four fields. Color subcarrier phase is reset to VENC_CPHASE[7:0] CPHS bit field value (offset 0x2C) upon reset	RW	0x3
16	SBLANK	Data output enable 0x0: No functionality 0x1: Enables the output of data when VENC_SYNC_CTRL[10] VBLMK bit is '0b1'.	RW	0
15:9	Reserved	Reserved. Read returns 0s.	RW	0x00
8:0	LAL	Last Active Line of Field. These bits define the last active line of a field. The LAL[8:0] bit field value must be set to a value lower than the active window.	RW	0x107

Table 7-366. VENC_OUTPUT_CONTROL

Address Offset	0x0000 00C4	Instance	VENC
Physical Address	0x4805 0CC4		
Description	Output channel control register Also contains some test control features		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								LUMA_TEST								RESERVED								CHROMA_SOURCE	COMPOSITE_SOURCE	LUMA_SOURCE	TEST_MODE	VIDEO_INVERT	CHROMA_ENABLE	COMPOSITE_ENABLE	LUMA_ENABLE

Bits	Field Name	Description	Type	Reset
31:26	RESERVED	Reserved. Read returns 0s.	RW	0x00
25:16	LUMA_TEST	In test mode, DAC 1 input value (if s-video video mode is selected)	RW	0x000
15:8	RESERVED	Reserved. Read returns 0s.	RW	0x00
7	CHROMA_SOURCE	Source of chroma video data in test mode 0x0: Chroma test data comes from internal register OUTPUT_TEST[25:16] 0x1: Chroma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
6	COMPOSITE_SOURCE	Source of composite video data in test mode 0x0: Composite test data comes from internal register OUTPUT_TEST[9:0] 0x1: Composite test data comes from display controller video port G[1:0], B[7:0]	RW	0x0

Bits	Field Name	Description	Type	Reset
5	LUMA_SOURCE	Source of luminance video data in test mode 0x0: Luma test data comes from internal register OUTPUT_CONTROL[25:16] 0x1: Luma test data comes from display controller video port G[1:0], B[7:0]	RW	0x0
4	TEST_MODE	This enables the video DACs to be tested. The values sent to the DACs comes from a register for each output channel (Luma, Composite or Chroma) or from the display controller video port bits G[1:0], B[7:0], depending on the setting of the Source bits 0x0: Video outputs are in normal operation 0x1: Test mode. Video outputs are directly connected to either internal registers or the display controller video port.	RW	0x0
3	VIDEO_INVERT	Controls the video output polarity. This may be used to correct for inversion in an external video amplifier. 0x0: Video outputs are inverted 0x1: Video outputs are normal polarity	RW	0x1
2	CHROMA_ENABLE	Enable the Chrominance output channel 0x0: Chroma output is disabled 0x1: Chroma output is enabled	RW	0x0
1	COMPOSITE_ENABLE	Enable the Composite output channel 0x0: Composite output is disabled 0x1: Composite output is enabled	RW	0x0
0	LUMA_ENABLE	Enable the Luminance output channel 0x0: Luma output is disabled 0x1: Luma output is enabled	RW	0x0

7.7.2.5 DSI Protocol Engine Registers

Table 7-370. DSI_REVISION

Address Offset	0x0000 0000	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC00		
Description	MODULE REVISION This register contains the IP revision code in binary coded digital. For example, we have: 0x01 = revision 0.1 and 0x21 = revision 2.1		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																REV															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Write 0s for future compatibility. Reads returns 0.	R	0x000000
7:0	REV	IP revision [7:4] Major revision [3:0] Minor revision	R	TI internal data

Table 7-372. DSI_SYSCONFIG

Address Offset	0x0000 0010	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC10		
Description	SYSTEM CONFIGURATION REGISTER This register is the system configuration register.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																RESERVED		CLOCKACTIVITY	RESERVED	SIDLEMODE	ENWAKEUP	SOFT_RESET	AUTO_IDLE								

Bits	Field Name	Description	Type	Reset
31:14	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00000
13:10	RESERVED	Write 0s for future compatibility.	RW	0x0
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period 0x0: Interface and Functional clocks can be switched off 0x1: Functional clocks can be switched off and Interface clocks are maintained during wake up period 0x2: Interface clocks can be switched off and Functional clocks are maintained during wake up period 0x3: Interface and Functional clocks are maintained during wake up period	RW	0x0
7:5	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
4:3	SIDLEMODE	Slave interface power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. 0x3: Reserved	RW	0x2
2	ENWAKEUP	Wake-up mode enable bit 0x0: Wakeup is disabled. 0x1: Wakeup is enabled,	RW	0x0
1	SOFT_RESET	Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hw. During reads return 0. 0x0: Normal mode. 0x1: The module is reset	RW	0x0
0	AUTO_IDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied based on the module interface activity.	RW	0x1

Bits	Field Name	Description	Type	Reset
31:21	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x000
20	TA_TO_IRQ	Turn-around Time out. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
19	LDO_POWER_GOOD_IRQ	Transition of the status signal LDOPWRGOOD from the DSI_PHY indicating a state change for the supply VDDALDODSIPLL from up to down or down to up. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
18	SYNC_LOST_IRQ	Synchronization with Video port is lost (Video mode only) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
17	ACK_TRIGGER_IRQ	Acknowledge Trigger 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
16	TE_TRIGGER_IRQ	Tearing Effect Trigger 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
15	LP_RX_TO_IRQ	Interrupt for Low Power Rx Time out 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
14	HS_TX_TO_IRQ	Interrupt for high-speed Tx Time out. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
13	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
12:11	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
10	COMPLEXIO_ERR_IRQ	Error signaling from complex I/O: status of the complex I/O errors received from the complex I/O(events are defined in DSI_COMPLEXIO_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
9	PLL_RECAL_IRQ	PLL recalibration event (assertion of recalibration signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0

Bits	Field Name	Description	Type	Reset
8	PLL_UNLOCK_IRQ	PLL un-lock event (de-assertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
7	PLL_LOCK_IRQ	PLL lock event (assertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
6	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
5	RESYNCHRONIZATION_IRQ	Video mode resynchronization Indicates that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI protocol engine may have to be modified to avoid the resynchronization to occur. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
4	WAKEUP_IRQ	Wakeup 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset.	RW	0x0
3	VIRTUAL_CHANNEL3_IRQ	Virtual channel #3 Error signaling from DSI Virtual Channel3: Status of DSI Virtual Channel3 errors received from DSI Virtual Channel3 (events are defined in DSI_VC3_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
2	VIRTUAL_CHANNEL2_IRQ	Virtual channel #2 Error signaling from DSI Virtual Channel2: Status of DSI Virtual Channel2 errors received from DSI Virtual Channel2 (events are defined in DSI_VC2_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
1	VIRTUAL_CHANNEL1_IRQ	Virtual channel #1 Error signaling from DSI Virtual Channel1: Status of DSI Virtual Channel1 errors received from DSI Virtual Channel1 (events are defined in DSI_VC1_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0
0	VIRTUAL_CHANNEL0_IRQ	Virtual channel #0 Error signaling from DSI Virtual Channel0: Status of the DSI Virtual Channel0 errors received from DSI Virtual Channel0 (events are defined in DSI_VC0_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending).	R	0x0

Table 7-380. DSI_CTRL

Address Offset	0x0000 0040	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC40		
Description	GLOBAL CONTROL REGISTER This register controls the DSI Protocol Engine module. This register should not be modified dynamically (except IF_EN bit field).		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED								RGB565_ORDER	DCS_CMD_CODE	DCS_CMD_ENABLE	HSA_BLANKING_MODE	HBP_BLANKING_MODE	HFP_BLANKING_MODE	BLANKING_MODE	EOT_ENABLE	VP_HSYNC_END	VP_HSYNC_START	VP_VSYNC_END	VP_VSYNC_START	TRIGGER_RESET_MODE	LINE_BUFFER	VP_VSYNC_POL	VP_HSYNC_POL	VP_DE_POL	VP_CLK_POL	VP_DATA_BUS_WIDTH	TRIGGER_RESET	VP_CLK_RATIO	TX_FIFO_ARBITRATION	ECC_RX_EN	CS_RX_EN	IF_EN

Bits	Field Name	Description	Type	Reset
31:27	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
26	RGB565_ORDER	Byte order for RBG565 command mode from video port 0x0: 0x1: Byte order as for video mode	RW	0
25	DCS_CMD_CODE	DCS command code value to insert between header and video port data when enabled by DCS_CMD_ENABLE 0x0: DCS write memory continue code is inserted. 0x1: DCS write memory start code is inserted.	RW	0
24	DCS_CMD_ENABLE	Enables automatic insertion of DCS command codes when data is sourced by the video port. 0x0: DCS command code is not inserted when command mode traffic is coming from the Video Port. 0x1: DCS command code is inserted automatically when command mode traffic is coming from the Video Port.	RW	0
23	HSA_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode.	RW	0x0
22	HBP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	HFP_BLANKING_MODE	Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode.	RW	0x0
20	BLANKING_MODE	Blanking mode 0x0: LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) when there is no command mode data in TX FIFO ready to be sent. So blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) regardless of the packets present in the TX FIFO ready to be sent	RW	0x0
19	EOT_ENABLE	Enable EOT packets at the end of HS transmission. 0x0: No EOT packets 0x1: EOT packet is sent at all HS to LP transitions	RW	0
18	VP_HSYNC_END	HSYNC end pulse. 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated.	RW	0x0
17	VP_HSYNC_START	HSYNC start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated.	RW	0x0
16	VP_VSYNC_END	VSYNC end pulse. 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated.	RW	0x0
15	VP_VSYNC_START	VSYNC start pulse. 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated.	RW	0x0
14	TRIGGER_RESET_MODE	Selection of the trigger reset mode 0x0: Synchronized: the mode is only valid if there is VC using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: all pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.	RW	0x0
13:12	LINE_BUFFER	Number of line buffers to be used while receiving data on the video port. 0x0: No line buffer 0x1: 1 line buffer 0x2: 2 line buffers	RW	0x0
11	VP_VSYNC_POL	VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high.	RW	0x0

Bits	Field Name	Description	Type	Reset
10	VP_HSYNC_POL	VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high.	RW	0x0
9	VP_DE_POL	VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high.	RW	0x0
8	VP_CLK_POL	VP pixel clock polarity 0x0: The DSI Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP must drive the data on the pixel clock rising edge. 0x1: The DSI Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP must drive the data on the pixel clock falling edge.	RW	0x1
7:6	VP_DATA_BUS_WIDTH	Defines the size of the video port data bus 0x0: 16-bits data width (LSB of the 24-bit video port data bus) 0x1: 18-bits data width (LSB of the 24-bit video port data bus) 0x2: 24-bits data width (LSB of the 24-bit video port data bus)	RW	0x0
5	TRIGGER_RESET	Send the reset trigger to the peripheral. 0x0: READS: Reset trigger generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the request for Reset trigger generation (maybe too late since it is already on going) 0x1: READS: Generation of the reset trigger has been requested by user (could be on going but not completed yet). WRITES: Request for Reset trigger to be sent to the peripheral.	RW	0x0
4	VP_CLK_RATIO	This bit indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used. 0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50. 0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3,5,7,...).	RW	0x0
3	TX_FIFO_ARBITRATION	Defines the arbitration scheme for granting the VC pending ready requests in the TX FIFO 0x0: Round-Robin Scheme is used 0x1: Sequential Scheme is used	RW	0x0
2	ECC_RX_EN	Enables the ECC check for the received header (short and long packets for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0
1	CS_RX_EN	Enables the checksum check for the received payload (long packet only for all VC IDs). 0x0: Disabled 0x1: Enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
0	IF_EN	<p>Enables the module. When the module is disabled the signals from the complex I/O are gated (no updates of the interrupt status register).</p> <p>It is not possible to change the bit fields in the DSI_CTRL register, except IF_EN when it is enabled. All the other registers can be changed except the ones that require DSI_VCn_CTRL[0] VC_EN to be equal to 0 to be modified.</p> <p>0x0: The interface is disabled. If one of the VC uses the video mode with the video port to receive the data, the DSI protocol engines is disabled when the next VSYNC is received and all the data in the FIFO for the other VCs in command mode are sent to the peripherals (if BTA_EN bit is enabled, the DSI protocol engine needs to wait for the response and BTA from the peripheral before disabling all the internal logic since an acknowledge is requested).</p> <p>0x1: The interface is enabled immediately, the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the Slave port FIFO (command mode).</p>	RW	0x0

Table 7-382. DSI_COMPLEXIO_CFG1

Address Offset	0x0000 0048	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC48		
Description	COMPLEXIO CONFIGURATION REGISTER for the complex I/O This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
SHADOWING	GOBIT	RESET_DONE	PWR_CMD	PWR_STATUS	RESERVED	RESERVED	RESERVED	LDO_POWER_GOOD_STATE	USE_LDO_EXTERNAL	RESERVED	RESERVED	RESERVED	RESERVED	RESERVED	RESERVED	DATA2_POL	DATA2_POSITION	DATA1_POL	DATA1_POSITION	CLOCK_POL	CLOCK_POSITION											

Bits	Field Name	Description	Type	Reset
31	SHADOWING	Shadowing configuration. 0x0: Disabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done like the other SCP registers. 0x1: Enabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done only when the GO bit is set and when the signal DISPC_UPDATE_SYNC from the display controller module is active.	RW	0x0
30	GOBIT	Allows the synchronized update of the shadow registers when the signal DISPC_UPDATE_SYNC is active. 0x0: Resets the Gobit. The hardware has finished the update of the shadow SCP registers. The bit is reset by Hardware. The software can reset the bit in case users decide to abort it. There is no guarantee that the software reset is done before the transfer of the values to the complex I/O. 0x1: Set the Gobit. Only when the transfer of the new values for the two first registers is completed (2, 1, or 0 transfers are performed based on the number of registers to update), the GObit is reset. The DISPC_UPDATE_SYNC signal is used to synchronize the update. The bit must be set only when it is in reset state.	RW	0
29	RESET_DONE	Internal reset monitoring of the power domain using the TxByteClkHS from the complex I/O 0x0: Internal module reset is on going. 0x1: Reset completed.	R	1
28:27	PWR_CMD	Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to ultralow-power state	RW	0x0
26:25	PWR_STATUS	Status of the power control of the complex I/O 0x0: complex I/O in OFF state 0x1: complex I/O in ON state 0x2: complex I/O in ultralow-power state	R	0x0
24:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0

Bits	Field Name	Description	Type	Reset
21	LDO_POWER_GOOD_STATE	Indicates the state of the signal LDOPWRGOOD. VDDALDODSIPLL: 1.2-V power supply for the PLL. The voltage is supplied by the internal or external LDO. The interrupt LDO_POWER_GOOD_IRQ is generated when a transition is detected on the signal LDOPWRGOOD from the DSI_PHY. 0x0: VDDALDODSIPLL power supply is down 0x1: VDDALDODSIPLL power supply is up	R	0x0
20	USE_LDO_EXTERNAL	Select the external LDO for the DSI_PHY. 0x0: DSI_PHY internal LDO is used. 0x1: External LDO is used. DSI_PHY LDO is tri-stated.	RW	0x0
19	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
18:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
15	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
14:12	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
11	DATA2_POL	+/- differential pin order of DATA lane 2. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
10:8	DATA2_POSITION	Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at the position 1 (line 1). 0x2: Data lane 2 is at the position 2 (line 2). 0x3: Data lane 2 is at the position 3 (line 3). Other values: reserved	RW	0x0
7	DATA1_POL	+/- differential pin order of DATA lane 1 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
6:4	DATA1_POSITION	Position and order of the DATA lane 1. 0x1: Data lane 1 is at the position 1 (line 1). 0x2: Data lane 1 is at the position 2 (line 2). 0x3: Data lane 1 is at the position 3 (line 3). Other values: reserved	RW	0x0
3	CLOCK_POL	+/- differential pin order of CLOCK lane. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+)	RW	0x0
2:0	CLOCK_POSITION	Position and order of the CLOCK lane. The clock lane is always present. 0x1: Clock lane is at the position 1 (line 1). 0x2: Clock lane is at the position 2 (line 2). 0x3: Clock lane is at the position 3 (line 3). Other values: reserved	RW	0x0

Table 7-388. DSI_CLK_CTRL

Address Offset	0x0000 0054	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC54		
Description	CLOCK CONTROL This register controls the CLOCK GENERATION. The register can be modified only when IF_EN is reset.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PLL_PWR_CMD		PLL_PWR_STATUS		RESERVED				LP_RX_SYNCHRO_ENABLE	LP_CLK_ENABLE	HS_MANUAL_STOP_CTRL	HS_AUTO_STOP_ENABLE	LP_CLK_NULL_PACKET_SIZE	LP_CLK_NULL_PACKET_ENABLE	CIO_CLK_ICG	DDR_CLK_ALWAYS_ON	LP_CLK_DIVISOR															

Bits	Field Name	Description	Type	Reset
31:30	PLL_PWR_CMD	Command for power control of the DSI PLL Control module 0x0: Command to change to OFF state 0x1: Command to change to ON state for PLL only (HSDIVISER is OFF) 0x2: Command to change to ON state for both PLL and HSDIVISER 0x3: Command to change to ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)	RW	0x0
29:28	PLL_PWR_STATUS	Status of the power control of the DSI PLL Control module 0x0: DSI PLL Control module in OFF state 0x1: DSI PLL Control module in ON state for PLL only (HSDIVISER is OFF) 0x2: DSI PLL Control module in ON state for both PLL and HSDIVISER 0x3: DSI PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O)	R	0x0
27:22	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
21	LP_RX_SYNCHRO_ENABLE	Defines if the DSI functional clock is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc. 0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising. 0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising.	RW	0x0
20	LP_CLK_ENABLE	Controls the gating of the TXCLKESC clock. 0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR[12:0] bit field is not used and does not have to be programmed. 0x1: Enabled. The clock is generated. The value of LP_CLK_DIVISOR[12:0] bit field is used and must be programmed.	RW	0x0
19	HS_MANUAL_STOP_CTRL	In case HS_AUTO_STOP_ENABLE bit is set to 0 (reset value), the bit field allows manual control of the assertion/de-assertion of the signal DSISStopClk by users. 0x0: DSISStopClk de-assertion unconditionally. 0x1: DSISStopClk assertion unconditionally.	RW	0x0
18	HS_AUTO_STOP_ENABLE	Enables the automatic assertion/de-assertion of DSISStopClk signal. 0x0: Auto mode disabled. 0x1: Auto mode enabled.	RW	0x0
17:16	LP_CLK_NULL_PACKET_SIZE	Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size.	RW	0x0
15	LP_CLK_NULL_PACKET_ENABLE	Enables the generation of NULL packet in low speed. 0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet. 0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet.	RW	0x0
14	CIO_CLK_ICG	Controls the signal for gating the L3_ICLK clock provided to the complex I/O 0x0: Disabled. The L3_ICLK clock to the DSI complex I/O is gated. 0x1: Enabled. The L3_ICLK clock to the DSI complex I/O is not gated.	RW	0x0

Bits	Field Name	Description	Type	Reset
13	DDR_CLK_ALWAYS_ON	Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low power mode). So TXRequest for the clock lane is not de-asserted. 0x0: Disabled. The DDR clock is only provided when HS packets are sent. 0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LP mode).	RW	0x0
12:0	LP_CLK_DIVISOR	Defines the ratio to be used for the generation of the low-power mode clock from DSI functional clock. The supported values are from 1 to 8191(the value 0 is invalid). The output frequency must be in the range between 20 MHz and 32 kHz.	RW	0x0001

Table 7-390. DSI_TIMING1

Address Offset	0x0000 0058	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC58		
Description	TIMING1 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while DSI_CTRL.IF_EN is set to 1. It is used to indicate the number of DSI_FCLK clock cycles for the timers FORCE_TX_STOP_TIMER and TA_TO_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TA_TO	TA_TO_X16	TA_TO_X8	TA_TO_COUNTER												FORCE_TX_STOP_MODE_IO	STOP_STATE_X16_IO	STOP_STATE_X4_IO	STOP_STATE_COUNTER_IO													

Bits	Field Name	Description	Type	Reset
31	TA_TO	Enables the turn-around timer 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
30	TA_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 16x	RW	0x1
29	TA_TO_X8	Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	TA_TO_COUNTER	Turn around counter. It indicates the number of DSI_FCLK clock cycles to wait for the change of the Direction PPI signal according to the TurnRequest signal The value is from 0 to 8191.	RW	0x1FFF
15	FORCE_TX_STOP_MODE_IO	Control of ForceTxStopMode signal 0x0: De-assertion of ForceTxStopMode. The hardware reset the bit at the end of the ForceTXStopMode assertion. The SW can reset the bit to stop the assertion of the ForceTXStopMode signal prior to the completion of the period. 0x1: Assertion of ForceTxStopMode	RW	0x0
14	STOP_STATE_X16_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 16x	RW	0x1
13	STOP_STATE_X4_IO	Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 4x	RW	0x1
12:0	STOP_STATE_COUNTER_IO	Stop state counter. It indicates the number of DSI_FCLK clock cycles to assert ForceTXStopMode signal. The value is from 0 to 8191.	RW	0x1FFF

Table 7-392. DSI_TIMING2

Address Offset	0x0000 005C	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC5C		
Description	TIMING2 REGISTER This register controls the DSI Protocol Engine module timers. Any bit field can be modified while DSI_CTRL.IF_EN is set to 1. It is used to indicate the number of TxByteClkHS clock cycles for the timers HS_TX_TIMER and LP_RX_TIMER		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
HS_TX_TO	HS_TX_TO_X16	HS_TX_TO_X8	HS_TX_TO_COUNTER													LP_RX_TO	LP_RX_TO_X16	LP_RX_TO_X4	LP_RX_TO_COUNTER												

Bits	Field Name	Description	Type	Reset
31	HS_TX_TO	Enables the HS TX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
30	HS_TX_TO_X16	Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit field 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 16x	RW	0x1
29	HS_TX_TO_X8	Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 8x	RW	0x1
28:16	HS_TX_TO_COUNTER	HS_TX_TIMER counter. It indicates the number of TxByteClkHS function clock cycles for the HS TX timer. The value is from 0 to 8191.	RW	0x1FFF
15	LP_RX_TO	Enables the LP RX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful).	RW	0x0
14	LP_RX_TO_X16	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 16x	RW	0x1
13	LP_RX_TO_X4	Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 4x	RW	0x1
12:0	LP_RX_TO_COUNTER	LP_RX_TIMER counter. It indicates the number of DSI_FCLK clock cycles for the LP RX timer. The value is from 0 to 8191.	RW	0x1FFF

Address Offset	0x0000 0064	Instance	DSI_PROTOCOL_ENGINE
Physical Address	0x4804 FC64		
Description	VIDEO MODE TIMING REGISTER This register defines the video mode timing.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED				WINDOW_SYNC				VSA				VFP				VBP															

Bits	Field Name	Description	Type	Reset
31:28	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
27:24	WINDOW_SYNC	Number of TxByteClkHS clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchronization on video port is not inside the window. The DSI protocol engine does not change its own timings if the synch is inside the window. The valid values are from 0 to 15.	RW	0x0
23:16	VSA	Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization.	RW	0x00
15:8	VFP	Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00
7:0	VBP	Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255	RW	0x00

Table 7-400. DSI_CLK_TIMING

Address Offset	0x0000 006C	
Physical Address	0x4804 FC6C	Instance DSI_PROTOCOL_ENGINE
Description	CLOCK TIMING REGISTER This register controls the DSI Protocol Engine module timers. This register should not be modified while DSI_CTRL.IF_EN is set to 1.	
Type	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED								DDR_CLK_PRE								DDR_CLK_POST															

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
15:8	DDR_CLK_PRE	Indicates the number of TxByteClkHS cycles between the start of the DDR clock and the assertion of the data request signal. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.	RW	0x01
7:0	DDR_CLK_POST	Indicates the number of TxByteClkHS cycles after the de-assertion of the data request signal and the stop of the DDR clock. The values from 1 to 255 are valid. The value 0 is reserved. The value is not used if DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON is set to 1 since the DDR clock is always present.	RW	0x01

Table 7-418. DSI_VM_TIMING7

Address Offset	0x0000 0090	
Physical Address	0x4804 FC90	Instance DSI_PROTOCOL_ENGINE
Description	Defines the maximum number of bytes of Low Power command mode packets that can be sent on PPI link during blanking periods during VSA, VBP or VFP periods inside one video frame on PPI link. The supported values are from 0 to 65535	
Type	RW	

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
ENTER_HS_MODE_LATENCY																EXIT_HS_MODE_LATENCY															

Bits	Field Name	Description	Type	Reset
31:16	ENTER_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 .	RW	0x0000
15:0	EXIT_HS_MODE_LATENCY	Defines the number of TxByteClkHS clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of TxByteClkHS from de-assertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535	RW	0x0000

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0
29:27	DMA_RX_REQ_NB	Selection of the use of the DMA request (associated to the RX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
26:24	DMA_RX_THRESHOLD	Defines the threshold value for the DMA request (associated to the RX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
23:21	DMA_TX_REQ_NB	Selection of the use of the DMA request (associated to the TX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected	RW	0x0
20	RX_FIFO_NOT_EMPTY	FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The RX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The RX FIFO is not empty (the FIFO contains at least one byte for the VC)	R	0x0
19:17	DMA_TX_THRESHOLD	Defines the threshold value for the DMA request (associated to the TX FIFO) 0x0: 1x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits	RW	0x0
16	TX_FIFO_FULL	FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) 0x1: The TX FIFO is full	R	0x0
15	VC_BUSY	Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 by hardware if VC is enabled. Software should check this bit is 0 before changing channel configuration. 0x0: No pending operations for this VC 0x1: Pending operations for this VC	R	0x0
14	PP_BUSY	Line buffer busy status. 0x0: Software is permitted to write a new header for VP command mode traffic. 0x1: Software is NOT permitted to write a new header for VP command mode traffic.	R	0

Bits	Field Name	Description	Type	Reset
13:10	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x00
9	MODE_SPEED	Selection of the mode. This bit is ignored by hardware when video mode is selected. 0x0: Low-power mode (CMOS) is used to send short and long packets to the peripheral. 0x1: High speed mode (SLVS) is used to send short and long packets to the peripheral.	RW	0x0
8	ECC_TX_EN	Enables the ECC generation for the transmit header (short and long packets). 0x0: Disabled 0x1: Enabled	RW	0x0
7	CS_TX_EN	Enables the checksum generation for the transmit payload (long packet only). 0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The Check-sum value is calculated by HW.	RW	0x0
6	BTA_EN	Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode allows users to define for which packets, the turn around is required for example getting acknowledge from the peripheral. 0x0: READS: BTA generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the BTA generation (not guarantee since it could already on going, must not be used). 0x1: READS: BTA generation has been requested by user (it could be on going but not completed). WRITES: Request for BTA generation.	RW	0x0
5	TX_FIFO_NOT_EMPTY	FIFO status 0x0: The TX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the VC)	R	0x0
4	MODE	Selection of the mode 0x0: Command mode. 0x1: Video mode.	RW	0x0
3	BTA_LONG_EN	Enables the automatic bus turn-around after completion of each long packet transmission. 0x0: Disabled 0x1: Enabled	RW	0x0
2	BTA_SHORT_EN	Enables the automatic bus turn-around after completion of each short packet transmission. 0x0: Disabled 0x1: Enabled	RW	0x0

Bits	Field Name	Description	Type	Reset
1	SOURCE	<p>Selection of the source between L4 interconnect slave port and video port. This bit is ignored by hardware when video mode is selected.</p> <p>0x0: All the data are provided by the L4 interconnect slave port. Any transfer on the video port is ignored for this VC.</p> <p>0x1: If MODE=VIDEO_MODE, any data received on the video port (pixels and enabled synchronization events using DSI_CTRL[17] VP_HSYNC_START, DSI_CTRL[18] VP_HSYNC_END, DSI_CTRL[15] VP_VSYNC_START, DSI_CTRL[16] VP_VSYNC_END,) are sent on the VC (only one VC can be associated with the video port, the software must ensure that no more than one VC is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP_STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the L4 interconnect slave port.</p>	RW	0x0
0	VC_EN	<p>Enables the VC.</p> <p>0x0: Disabled. The VC must be disabled for any register change in the DSI_VCn_XXX registers the corresponding VC ID.</p> <p>0x1: Enabled. No change is allowed to the VC registers (except for setting the bit fields/registers: DSI_VCn_CTRL[6] BTA_EN, DSI_VCn_TE[15:0] TE_SIZE, DSI_VCn_TE[31] TE_START, DSI_VCn_LONG_XXX, DSI_VCn_SHORT_XXX, DSI_VCn_IRQXXX registers).</p>	RW	0x0

Table 7-424. DSI_VCn_TE

Address Offset	0x0000 0104+ (n* 0x20)	Index	n = 0 to 3
Physical Address	0x4804 FD04+ (n* 0x20)	Instance	DSI_PROTOCOL_ENGINE
Description	CONTROL REGISTER - Virtual channel This register controls the tearing effect logic. It defines the size of the transfer when TE occurs and enables the automatic TE mode.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TE_START	TE_EN	RESERVED						TE_SIZE																							

Bits	Field Name	Description	Type	Reset
31	TE_START	Manual control of the start of the transfer. Users can use the TE interrupt to determine that the TE trigger has been received before setting the TE_START bit field. It is not mandatory to use the TE interrupt. 0x0: Indicates the end of the transfer. The bit can be used to cancel the transfer if not already started. The FIFO must be flushed by software to ensure it contains no remaining data. 0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit field is set until the transfer completes. It is reset by hardware when the transfer completes.	RW	0
30	TE_EN	Tearing effect control 0x0: Disables the automatic transfer of the data using the TE trigger as a synchronization event. The interruption is used to know when the TE trigger is received. The hardware resets the bit field when the transfer completes(TE_SIZE=0). 0x1: Enables the automatic transfer of the data using the TE trigger as a synchronization event.	RW	0
29:24	RESERVED	Write 0s for future compatibility. Reads returns 0.	RW	0x0000
23:0	TE_SIZE	Defines the number of bytes (payload data excluding the check-sum) to be sent. Users must perform the write into the DSI_VCn_LONG_PACKET_HEADER register before sending data from the DSI_VCn_LONG_PACKET_PAYLOAD register. The register value is decremented for every byte of the DSI link that is sent. At the end of the transfer (TE_SIZE = 0), the TE_EN bit field is reset by hardware. The DMA_request is asserted when the trigger is received in order to receive data in the TX FIFO. It must not be used until all data (TE_SIZE) have been received in the FIFO.	RW	0x000000

Table 7-428. DSI_VCn_LONG_PACKET_PAYLOAD

Address Offset	0x0000 010C+ (n* 0x20)	Index	n = 0 to 3
Physical Address	0x4804 FD0C+ (n* 0x20)	Instance	DSI_PROTOCOL_ENGINE
Description	LONG PACKET PAYLOAD INFORMATION - virtual channel. This register sets the payload information (excluding Check-sum). Hardware must capture the word count in the packet header (in DSI_VCn_LONG_PACKET_HEADER register) to determine the last valid data (the VC ID can be different from VC). Byte1 is bit[7:0]; Byte2 is bit[15:8]; Byte3 is bit[23:16]; Byte4 is bit[31:24]; and Byten is sent before Byten+1 (least-significant byte first and least significant bit first).

Bits	Field Name	Description	Type	Reset
31:29	REG_TTAGO	TTA-GO timing in terms of number of TXCLKESC clocks 0x0: 2 cycles 0x1: 3 cycles 0x2: 4 cycles 0x3: 5 cycles 0x4: 6 cycles 0x5: 7 cycles 0x6: 8 cycles 0x7: 9 cycles Default value: 4 cycles	RW	0x2
28:27	REG_TTASURE	TTA-SURE timing in terms of number of TXCLKESC clocks 0x0: 2 cycles 0x1: 1 cycle 0x2: 3 cycles 0x3: 4 cycles Default value: 2 cycles	RW	0x0
26:24	REG_TTAGET	TTA-GET timing in terms of number of TXCLKESC clocks	RW	0x2

Bits	Field Name	Description	Type	Reset
		0x0: 3 cycles 0x1: 4 cycles 0x2: 5 cycles 0x3: 6 cycles 0x4: 7 cycles 0x5: 8 cycles 0x6: 9 cycles 0x7: 10 cycles Default value: 5 cycles		
23:21	RESERVED	Reserved.	R	0x0
20:16	REG_TLPXBY2	(TLPX)/2 timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN4DDR/4. Default value is programmed for 400 MHz This is the internal timer value. The value seen on line will have variance due to rise/fall mismatch effects. Note: TLPX is used to define the length of LP-01 state in HS Start of Transmission sequences on clock and data lanes. For all other purposes TLPX is defined by the period of TxLPEsc clock.	RW	0x0A
15:8	REG_TCLKTRAIL	REG_TCLKTRAIL timing parameter in multiples of DDR clock frequency. DDR clock = CLKIN4DDR/4. D-PHY specification: 60 ns Default value is programmed for 400 MHz.	RW	0x1A
7:0	REG_TCLKZERO	REG_TCLKZERO timing parameter in multiples of DDR clock period. DDR clock = CLKIN4DDR/4. D-PHY specification: (REG_TCLKPREPARE + REG_TCLKZERO) 300 ns Derived specification for REG_TCLKZERO (Min REG_TCLKPREPARE = 38 ns): REG_TCLKZERO 262 ns Default value is programmed for 400 MHz.	RW	0x6A

2D/3D Graphics Accelerator

This chapter describes the 2D/3D graphics accelerator (SGX) for the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

NOTE: The SGX subsystem is a Texas Instruments instantiation of the POWERVR® SGX530 core from Imagination Technologies Ltd.

This document contains materials that are ©2003-2007 Imagination Technologies Ltd.

POWERVR® and USSE™ are trademarks or registered trademarks of Imagination Technologies Ltd.

8.1 SGX Overview	1962
8.2 SGX Integration	1965
8.3 SGX Functional Description	1967
8.4 SGX Register Manual	1969

8.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR® SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR SGX530 v1.2.5 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

Figure 8-1 shows the SGX subsystem in the device.

Figure 8-1. Graphics Accelerator Highlight

sgx-001

The SGX graphics accelerator can simultaneously process various multimedia data types:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

This is achieved through a multithreaded architecture using two levels of scheduling and data partitioning enabling zero-overhead task switching.

The SGX subsystem is connected to the L3 interconnect by a 128-bit master and a 32-bit slave interface.

8.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- Universal scalable shader engine (USSE™) – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0

- Industry-standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualized memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]
- 32K stride support

8.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
 - Cube map
 - Projected textures
 - 2D textures
 - Nonsquare textures
- Texture formats:
 - RGBA 8888, 565, 1555
 - Monochromatic 8, 16, 16f, 32f, 32int
 - Dual channel, 8:8, 16:16, 16f:16f
 - Compressed textures PVR-TC1, PVR-TC2, ETC1
 - Programmable support for all YUV formats
- Resolution support:
 - Frame buffer maximum size = 2048 x 2048
 - Texture maximum size = 2048 x 2048
- Texture filtering:
 - Bilinear, trilinear
 - Independent minimum and maximum control
- Antialiasing:
 - 4x multisampling
 - Up to 16x full scene anti-aliasing
 - Programmable sample positions
- Indexed primitive list support
 - Bus mastered
- Programmable vertex DMA
- Render to texture:
 - Including twiddled formats
 - Auto MipMap generation
- Multiple on-chip render targets (MRT).
Note: Performance is limited when the on-chip memory is not available.

8.1.3 Universal Scalable Shader Engine (USSE) – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

- Single programming model:
 - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
 - Zero-cost swapping in, and out, of threads
 - Cached program execution model
 - Dedicated pixel processing instructions
 - Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
 - 32-bit IEEE float
 - 2-way 16-bit fixed point
 - 4-way 8-bit integer
 - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
 - Subroutine calls
 - Loops
 - Conditional branches
 - Zero-cost instruction predication
- Procedural geometry:
 - Allows generation of primitives
 - Effective geometry compression
 - High-order surface support
- External data access:
 - Permits reads from main memory using cache
 - Permits writes to main memory
 - Data fence facility
 - Dependent texture reads

8.2 SGX Integration

Figure 8-2 highlights the SGX subsystem integration in the device.

Figure 8-2. SGX Subsystem Integration

8.2.1 Clocking, Reset, and Power-Management Scheme

8.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SGX_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device. The SGX clock tree is depicted in the *SGX Power Domain Clocking Scheme* figure in [Chapter 3, Power, Reset, and Clock Management](#).

Table 8-1. Clock Descriptions

Signal Name	I/O ⁽¹⁾	Description
SGX_FCLK	I	Functional clock (two possible clock sources) → Functional clock domain
SGX_ICLK	I	Interface clock (L3 interconnect clock domain) → Interface clock domain

⁽¹⁾ I =Input; O=Output

- The SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports. The source of SGX_ICLK is the PRCM clock (SGX_ICLK), which belongs to the SGX clock domain and runs at the L3 interconnect clock speed. The SGX_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see [Chapter 3, Power, Reset, and Clock Management](#).
When no longer required by the SGX subsystem, SGX_ICLK can be disabled by software at the PRCM level by setting the PRCM.CM_ICLKEN_SGX[0] EN_SGX bit to 0. For more information, see

the *SGX Power Domain Clock Controls* section in [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: SGX_ICLK is cut only if the SGX is ready to go into idle state. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

The source of SGX_FCLK is shown in the *SGX Power Domain Clock Controls* section of the [Chapter 3, Power, Reset, and Clock Management](#) chapter. Selection is made at the PRCM level by setting the PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX bit field (see the *GFX Functional Clock Ratio Settings* table in [Chapter 3, Power, Reset, and Clock Management](#)).

Depending on the clock source selection and DPLL settings, SGX_FCLK can support a frequency up to 200 MHz.

SGX_FCLK gating depends on the PRCM.CM_FCLKEN_SGX[1] EN_SGX bit. Clearing this bit to 0 indicates that both SGX clocks are no longer needed and can be cut at the PRCM level if the module is ready to enter the idle state. For more information, see the *SGX Power Domain* section in [Chapter 3, Power, Reset, and Clock Management](#).

8.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_RSTCTRL_SGX[0] SGX_RST bit.

8.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See [Chapter 3, Power, Reset, and Clock Management](#), for additional information about the SGX power domain.

As described in [Section 8.2, SGX Integration](#), the SGX subsystem receives two clock signals from the PRCM module. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

8.2.2 Hardware Requests

8.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_21.

8.3 SGX Functional Description

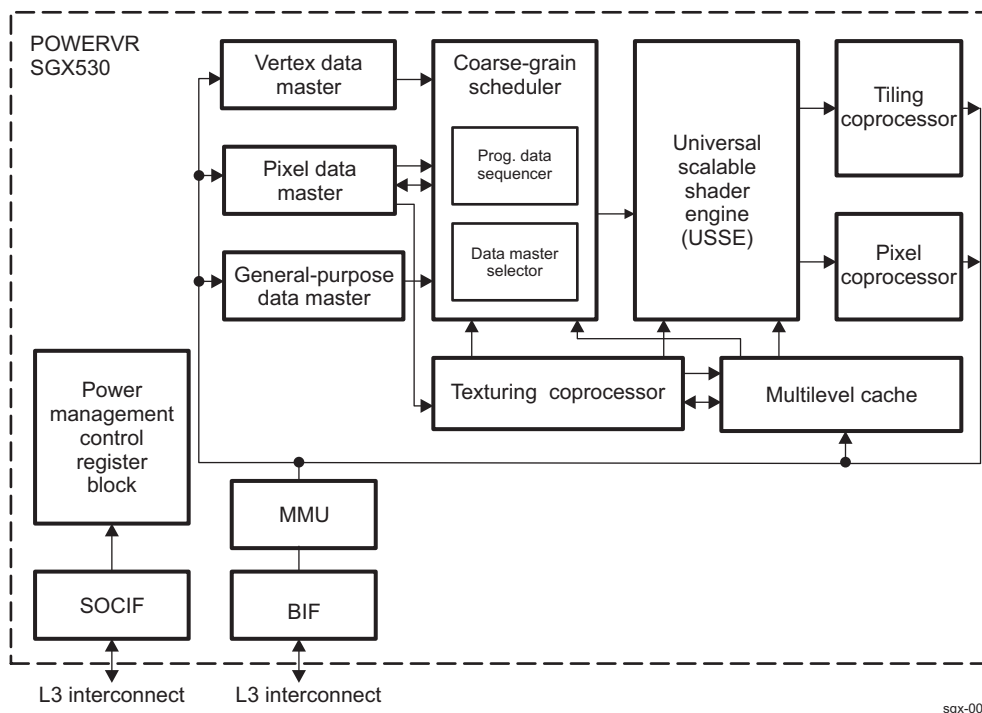

8.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR® SGX530 core from Imagination Technologies. The architecture uses programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
 - Programmable data sequencer (PDS)
 - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 8-3 shows a block diagram of the SGX cores.

Figure 8-3. SGX Block Diagram

8.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an

input control stream, which contains triangle index data and state data. The state data indicates the PDS program, size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.

- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to locality of data. It determines the amount of resource required within the USSE for each task. It merges this with the state address and issues a request to the DMS for execution on the USSE.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbitrator/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration, as well as any required texture decompression, are performed between the three data streams.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests in the multilevel cache. Data returned from the cache are then formatted according to the texture format selected, and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer and then USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

8.4 SGX Register Manual

CAUTION

All SGX registers are limited to 32-bit data accesses, 8- and 16-bit accesses are not allowed because they can corrupt register content.

Interconnect

This chapter describes the Interconnect.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

NOTE:

- The L3 interconnect is an instantiation of the **SonicsMX**® interconnect from Sonics, Inc.
- The L4 interconnects are instantiations of the **Sonics3220** interconnect from Sonics, Inc.

This document contains materials that are ©2003-2009 Sonics, Inc., and that constitute proprietary information of Sonics, Inc.

SonicsMX and Sonics3220, are trademarks or registered trademarks of Sonics, Inc. All such materials and trademarks are used under license from Sonics, Inc. For additional information, see the SonicsMX or Sonics3220 Reference manuals, or contact Sonics, Inc.

SMX is an abbreviation for SonicsMX.

NOTE: This chapter gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

9.3 L4 Interconnects	2051

9.1 Interconnect Overview

9.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- **Initiator:** Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- **Target:** Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be both an initiator and a target.

- **Agent:** Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- **OCP:** Open-core protocol (www.ocpip.org) is point-to-point standard protocol between one master port and one slave port.
- **OCP master port:** Port that can generate OCP commands. An initiator includes at least one master port.
- **OCP slave port:** Port that responds to OCP commands. A target includes one slave port.
- **Interconnect:** The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- **Register target (RT):** Special TA used to access the interconnect internal configuration registers
- **Dataflow signal:** Any OCP signal that is part of a clearly identified OCP transfer or dataflow (typically: command, address, byte enables, etc.). The signal behavior is defined by the OCP protocol semantics.
- **Sideband signal:** Any OCP signal whose behavior is not associated to a precise OCP transaction or dataflow. The OCP standard does not define specific semantics for these signals.
- **Out-of-band error:** Any OCP signal whose behavior is associated to an error-reporting scheme of the device, as opposed to in-band errors.

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- **Firewall:** A programmable feature integrated in a target agent or L4 interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
 - Initiator requesting access
 - Address space access
 - Type of access
- **Thread:** Logical entities that allow to have separate independent data flows on a single port.
- **Multithreaded ports:** A physical port able to simultaneously handle several outstanding transactions. On a multithreaded port, one physical channel (port) is used concurrently for several logical channels (threads). The transfer in each thread must remain in order with respect to each other, but the order between threads can change between requests and responses. Thread management is used for performance optimization purposes and is automatically handled by the system.
- **ConnID:** Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted inband with the request and is used for firewall and error-logging mechanism.
- **Firewall comparison mechanism:** A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- **MCmd qualifier:** Command bus that indicates the type of transfer requested. [Table 9-1](#) lists the commands encoded.

Table 9-1. MCmd Qualifier Description

MCmd[2:0]	Transaction Type
0 0 0	Idle
0 0 1	Write
0 1 0	Read
0 1 1	ReadEx
1 0 0	Not used
1 0 1	Write nonposted
1 1 0	Not used
1 1 1	Not used

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in [Table 9-2](#).

Table 9-2. MReqInfo Qualifier Description

Qualifiers	Description
MReqType	0: Data access
	1: Opcode fetch
MReqSupervisor	0: User mode
	1: Supervisor mode
MReqDebug	0: Functional access
	1: Debug access

- [L3_PM_REQ_INFO_PERMISSION_i](#): Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction.

Table 9-3. SResp Qualifier Description

SResp[1:0]	Description
0 0	No response
0 1	Data valid/accept
1 0	Not used
1 1	Error

9.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core and the IVA2.2 core.
- L2 is included in the IVA2.2 subsystem and the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and four L4 interconnects. It enables communication among the modules and subsystems in the device.

[Figure 9-1](#) shows an overview of the L3 and L4 interconnect architecture.

- L3 handles many types of data transfers, especially exchanges with system-on-chip/external memories. L3 transfers data with a maximum width of 64 bits from the initiator to the target. The L3 interconnect is a little-endian platform
- L4 is composed of the L4-Core, L4-Per, L4-Wakeup, and L4-Emu interconnects and handles data transfers to peripherals. It supports 32-bit data width transfer and is optimized to support the interconnection of many peripheral targets. These backplanes assume little-endian transactions for narrower targets (8-bit, 16-bit) when doing data packing and unpacking.

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default setting is fully functional; it enables all possible functional data paths and a minimal default protection setting. However, it is possible to modify the interconnect parameters to fit user expectations.

9.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

[Table 9-4](#) through [Table 9-13](#) list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3 initiator and target agents
- L4-Core initiator and target agents
- L4-Per initiator and target agents
- L4-Emu initiator and target agents
- L4-Wakeup initiator and target agents

9.1.3.1 L3 Interconnect Agents

[Table 9-4](#) and [Table 9-5](#) list the IAs and TAs, respectively, of the L3 interconnect.

Table 9-4. L3 Initiator Agents

Module Name	Description
MPU SS	MPU subsystem port
Display SS	Display subsystem port
IVA2.2 SS	IVA2.2 subsystem port
SGX SS	Graphics subsystem port
CAMERA SS	Camera subsystem port
SAD2D	Die-to-die port
sDMA read	System DMA read port
sDMA write	System DMA write port
High-Speed (HS) USB OTG	Universal Serial Bus High-Speed port OTG controller
High-Speed (HS) USB Host	Universal serial bus High-Speed port host controller
DAP	Debug access port (JTAG/Emulation access to system resources)

Table 9-5. L3 Target Agents

Module Name	Description
SMS	SDRAM memory scheduler port
GPMC	General-purpose memory controller (for flash memory, SRAM, SROM, etc.) port
OCM-ROM	On-chip memory ROM port
OCM-RAM	On-chip memory RAM port
SGX	Graphics subsystem port
IVA2.2	Image video and audio accelerator subsystem port
RT	Register target port to configure L3
L4-Core	Port for L4-Core interconnect
L4-Peripherals	Port for L4-Per interconnect

Table 9-5. L3 Target Agents (continued)

Module Name	Description
L4-Emu	Port for L4-Emu interconnect

For more details on the register target module, see [Section 9.2.3.2, Register Target](#).

9.1.3.2 L4-Core Agents

Table 9-6. L4-Core Initiator Agent

Module Name	Description
L3 interconnect	L3 interconnect port

NOTE: A unique L3 port is used for communication with the L4-Core. For the list of initiators allowed to access the L4 Core peripherals, see [Table 9-14](#).

Table 9-7. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
Camera subsystem	Camera subsystem port
High-Speed (HS) USB OTG	Universal serial bus High-speed port OTG
High-Speed (FS) USB Host	Universal serial bus High-Speed port Host controller
UART1	Universal asynchronous receiver transmitter port 1
UART2	Universal asynchronous receiver transmitter port 2
I2C1	Multimaster interintegrated circuit 1
I2C2	Multimaster interintegrated circuit 2
I2C3	Multimaster interintegrated circuit 3
McBSP1	Multichannel buffered serial port 1
McBSP5	Multichannel buffered serial port 5
GPTIMER10	General-purpose timer 10
GPTIMER11	General-purpose timer 11
MMC1	Multimedia memory controller SDIO 1
MMC2	Multimedia memory controller SDIO 2
MMC3	Multimedia memory controller SDIO 3
HDQ/1-Wire	Single wire serial link low rate
MLB (Mailbox)	Mailbox
MCSP11	Serial peripheral interface 1
MCSP12	Serial peripheral interface 2
MCSP13	Serial peripheral interface 3
MCSP14	Serial peripheral interface 4
SR1	SmartReflex1
SR2	SmartReflex2
sDMA	System DMA controller
L4-Wakeup	L4-Wakeup interconnect
CM	Clock manager
SCM	System control module

9.1.3.3 L4-Per Agents

Table 9-8. L4-Per Initiator Agent

Module Name	Description
L3 interconnect	L3 interconnect port

NOTE: A unique L3 port is used for communication with L4-Per. For the list of initiators allowed to access the L4-Per peripherals, see [Table 9-14](#).

Table 9-9. L4-Per Target Agents

Module Name	Description
UART3	Universal asynchronous receiver/transmitter and infrared data association port
UART4	Universal asynchronous receiver transmitter port 4
McBSP2	Multichannel buffered serial port 2
McBSP3	Multichannel buffered serial port 3
GPTIMER2	General-purpose timer 2
GPTIMER3	General-purpose timer 3
GPTIMER4	General-purpose timer 4
GPTIMER5	General-purpose timer 5
GPTIMER6	General-purpose timer 6
GPTIMER7	General-purpose timer 7
GPTIMER8	General-purpose timer 8
GPTIMER9	General-purpose timer 9
GPIO2	General-purpose I/O 2
GPIO3	General-purpose I/O 3
GPIO4	General-purpose I/O 4
GPIO5	General-purpose I/O 5
GPIO6	General-purpose I/O 6

9.1.3.4 L4-Emu Agents

Table 9-10. L4-Emu Initiator Agents

Module Name	Description
L3 interconnect	L3 interconnect port
DAP	DAP port

NOTE: The L3 and DAP ports are used for communication with L4-Emu. For the list of initiators allowed to access the L4-Emu peripherals, see [Table 9-14](#).

Table 9-11. L4-Emu Target Agents

Module Name	Description
L4-Wakeup	L4 wake-up interconnect
SDTI	System debug trace interface
ETB	Embedded trace buffer
TPIU	Trace port interface unit

Table 9-11. L4-Emu Target Agents (continued)

Module Name	Description
MPU	ARM9™
DAP	Debug access port

9.1.3.5 L4-Wakeup Agents

Table 9-12. L4-Wakeup Initiator Agent

Module Name	Description
L4-Core interconnect	L4-Core interconnect port
L4-Emu interconnect	L4-Emulation interconnect port

NOTE: The L4-Emu and L4-Core ports are used to communicate with the L4-Wakeup. For the list of initiators allowed to access the L4-Wakeup peripherals, see [Table 9-14](#).

Table 9-13. L4-Wakeup Target Agents

Module Name	Description
PRM	Power reset management
GPIO1	General-purpose I/O 1
GPTIMER1	General-purpose timer 1
WDTIMER2	MPU subsystem watchdog timer
32KTIMER	32-kHz timer

9.1.4 Connectivity Matrix

[Table 9-14](#) lists the functional paths between the L3 interconnect initiator modules and the L3 and L4 TAs. The functional paths are indicated by the use of the following:

- Cell contains a + sign when a functional path exists.
- Cell is blank when no functional path exists.

Table 9-14. Connectivity Matrix

Initiator Ports	L4-Core Target ⁽¹⁾	L4-Per Target ⁽¹⁾	L4-Emu Target ⁽¹⁾	L4-Wakeup Target ⁽¹⁾	SMS Target	GPMC Target	OCM RAM Target	OCM ROM Target	RT Target	IVA2.2 Target	SGX Target	MAD2D
MPU IA	+	+	+	+	+	+	+	+	+	+	+	+
SGX IA					+	+	+					+
IVA2.2 IA	+	+	+	+	+	+	+		+	+		+
DSS IA					+		+					+
CAM IA					+		+					+
HS USB Host IA					+	+	+					+
HS USB OTG IA					+	+	+					+
sDMA RD IA	+	+	+	+	+	+	+			+	+	+
sDMA WR IA	+	+	+	+	+	+	+			+	+	+

⁽¹⁾ A functional data path always exists from L4 IAs (Core, Per, Emu, and Wakeup) to any L4 target module (Core, Per, Emu, and Wakeup). As a consequence, all L3 initiator modules for which a data path exists to an L4 TA can access L4 peripherals. Restrictions on peripheral access depend on L4 protection mechanism. For more details, see [Section 9.3.3.3](#).

Table 9-14. Connectivity Matrix (continued)

Initiator Ports	L4-Core Target ⁽¹⁾	L4-Per Target ⁽¹⁾	L4-Emu Target ⁽¹⁾	L4-Wakeup Target ⁽¹⁾	SMS Target	GPMC Target	OCM RAM Target	OCM ROM Target	RT Target	IVA2.2 Target	SGX Target	MAD2D
DAP IA	+	+	+	+	+	+	+	+	+	+	+	+
SAD2D IA	+	+	+	+	+	+	+					

9.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functionality for both the request and response network.

9.2.1 Overview

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

Figure 9-2 shows the L3 interconnect.

intc-007

The following are the main features of the L3 interconnect:

- 64-bit multipath interconnect to eliminate on-chip bottlenecks
- Special internal target for access to L3 registers (RT)
- Guaranteed quality of service for real-time hardware operators, while maintaining optimal memory latency for MPU accesses to memory resources
- True little-endian platform
- Transaction error tracking and logging
- Built-in protection features:
 - Allow access only to authorized initiator
 - Distributed region-based firewalls for system resource sharing and protection management
- Signaling support for chip-level power management infrastructure
- Two interrupt line signaling transaction error

9.2.2 L3 Interconnect Integration

9.2.2.1 Clocking, Reset, and Power-Management Scheme

9.2.2.1.1 Clocks

The power, reset, and clock management (PRCM) module provides the L3_ICLK as the main clock to the L3 interconnect.

In addition to L3_ICLK, two additional sample signals are provided to module agents to allow internal synchronization. The modules are as follows:

- L4-Core
- L4-Per

For more details on the L3 clock and its setting, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 9-15. L3 Interconnect Clocks

Type	Name	Source	Description
Interface/functional	L3_ICLK	PRCM	Main clock for L3 interconnect

9.2.2.1.2 Resets

The L3 interconnect receives a single reset signal, CORE_RST, from the PRCM module. CORE_RST is the reset signal to the core power domain. (For more details see [Power, Reset, and Clock Management](#).) When asserted, CORE_RST resets the L3 internal registers. There is no software reset for the L3 interconnect.

Table 9-16. L3 Interconnect Reset

Type	Reset Domain	Source	Description
Hardware	CORE_RST	PRCM	Asynchronous reset for the entire interconnect

9.2.2.1.3 Power Domain

The L3 interconnect connects into the CORE power domain, which can dynamically switch between supported OPPs. For more details on power voltage scaling, see [Power, Reset, and Clock Management](#).

Table 9-17. L3 Interconnect Power Domain

Interconnect	Power Domain
L3 interconnect	CORE

9.2.2.1.4 Power Management

As part of the system-wide power-management scheme, the L3 interconnect enters an idle state at the request of the PRCM module. (For more details, see [Chapter 3, Power, Reset, and Clock Management](#).) The L3 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all transfer requests are serviced. This functionality is handled by hardware. The L3 interconnect sends an acknowledge signal back to the PRCM module when it enters the idle state.

9.2.2.2 Hardware Requests

9.2.2.2.1 Interrupt Requests

Three interrupt lines are present at the boundary of the L3 interconnect (see [Table 9-18](#)). They are used for hardware error management.

Table 9-18. L3 Interconnect Hardware Requests

Type	Name	Destination	Description
Interrupt	M_IRQ_9	MPU interrupt controller for debug errors	L3 interconnect provides a mechanism to group core-detected and internal interconnect errors. See Section 9.3.3.4, Error Handling .
Interrupt	M_IRQ_10	MPU interrupt controller for application errors	
Interrupt	IVA2_IRQ[39]	IVA2.2 interrupt controller for application errors	

9.2.3 L3 Interconnect Functional Description

9.2.3.1 Initiator Identification

An InitiatorID is assigned to every thread on every initiator socket. The ID uniquely identifies the initiator and thread for an interconnect transfer see [Table 9-19](#). The interconnect uses InitiatorIDs for a number of purposes, including the following:

- Initiator source identification for the protection mechanism (see [Section 9.2.3.3, L3 Protection and Firewalls](#))
- Response route generation (performed internally to the TAs)
- Firewall error logging
- L3 interconnect error logging

Table 9-19. InitiatorID Definition

Initiator	InitiatorID
HS USB Host	0
HS USB OTG	2
sDMA rd	3, 4, 5, 6
sDMA wr	7, 8
DAP	9
CAM	10, 11, 12
SGX	13
IVA2.2 SS DMA	14, 15, 16, 17, 18, 19
IVA2.2 SS	20, 21, 22
MPU SS	23, 24, 25, 26, 27
SAD2D	28
DSS	29

9.2.3.2 Register Target

An RT is a specialized TA used to access L3 interconnect internal configuration registers.

RT configuration options are a subset of those available for TAs. For more details, see [Section 9.2.5.3](#).

9.2.3.3 L3 Protection and Firewalls

Protection in the device relies heavily on L3 firewalls and their configuration. Nine targets are protected through the use of firewalls. The number of protected regions varies on the target, with a maximum of eight regions. [Table 9-20](#) lists the protection type and the number of protected regions for each target.

Table 9-20. Target Firewall and Region Configuration

Target	Firewall	Number of Regions
SMS	Included in the SMS module	See <i>Memory Subsystem</i> .
GPMC	Yes	8
OCM-RAM	Yes	8
OCM-ROM	Yes	3
MAD2D	Yes	8
SGX Target	No	0
IVA2.2 target	Yes	4
L4-Core	Included in the L4 module	See Section 9.3 , <i>L4 Interconnects</i> .
L4-Wakeup	Included in the L4 module	See Section 9.3 , <i>L4 Interconnects</i> .
L4-Emu	Included in the L4 module	See Section 9.3 , <i>L4 Interconnects</i> .
RT	Yes	2

The protection mechanism designates protection regions within the address space of certain targets. Access to these regions is granted only for certain initiators, based on transaction attributes (transmitted through MReqInfo). Each protection region is characterized with several configurable attributes (base address, size, specific access rights, and priority setting).

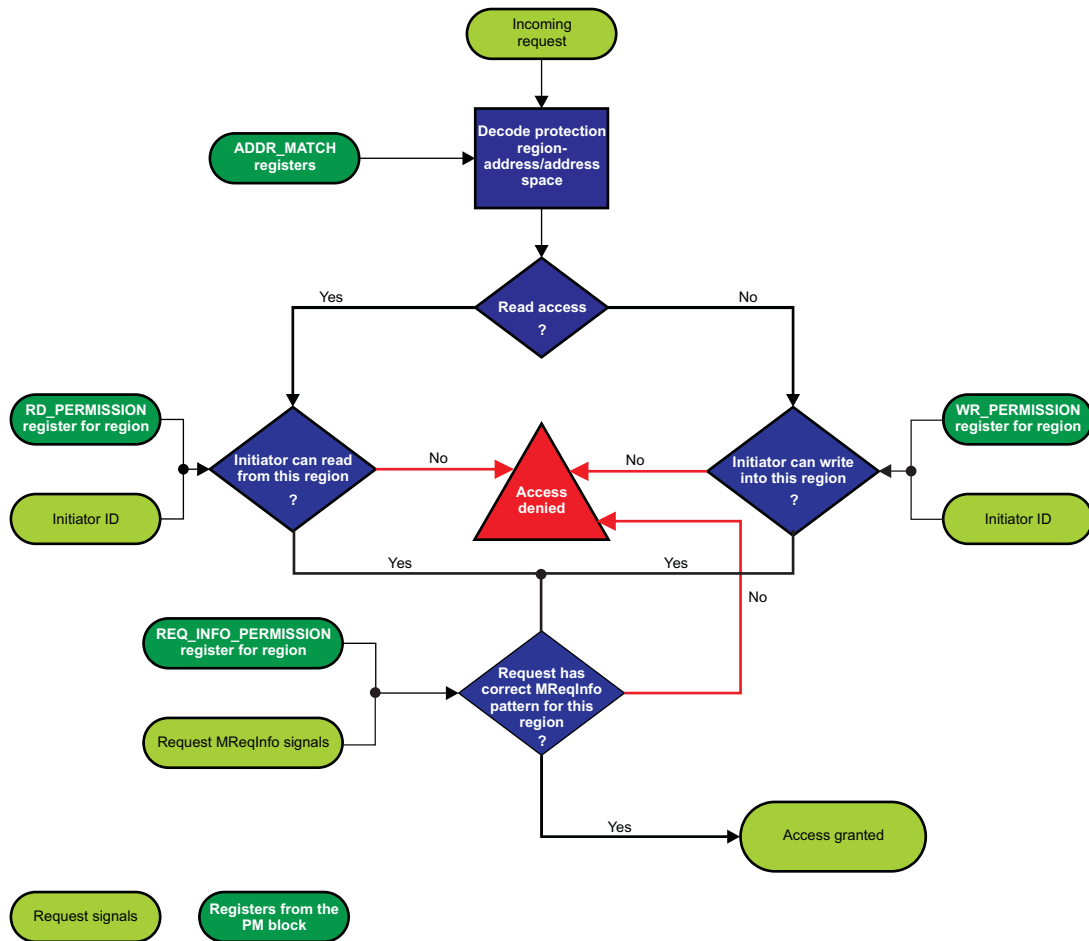

The protection mechanism uses the following attributes of a request:

- The address field and the address space field are used to determine which region has been hit. The region ID selects one table entry of the firewall look-up table.
- The region ID points to a unique set of permission registers: Read_Permission, Write_Permission, ReqInfo_Permission.
- The Initiator ID is used to determine the permission of the initiator (read/write permission) with respect to the concerned region.
- The access types (read or write) and the transaction attributes (MReqInfo in-band qualifiers) are used to grant or reject the access.

The first check determines whether the type of incoming request (read or write) is allowed, according to the Initiator MConnID and its read and write permissions. The second check determines whether the MReqInfo bits of the incoming request are within the allowed pattern established by the MReqInfo permission bits. If both check results are positive, the request is allowed to access the target. Otherwise, the access is denied, the request is not forwarded to the target, an out-of-band error indication is reported, and an in-band error response is returned to the initiator (except for writes that were posted at the IA).

[Figure 9-3](#) shows the flow used to identify and accept a new request.

Figure 9-3. Flow Chart of the Protection Mechanism

intc-014

To summarize, firewalls accept or reject a request depending on the following:

- Initiator originating the request
- Command (read or write) requested
- MReqInfo bus state
- Region access in the target memory space

Software must configure the L3 firewalls properly to allow the right initiators, with the right MReqInfo access, on the well-defined size region. All the registers relative to the L3 firewalls are grouped in the protection mechanism (PM) register block.

NOTE: The PM qualifies the protection mechanism register associated with a firewall target. The targets protected by a firewall are listed in [Table 9-20](#). These PM registers do not exist if no firewall is associated with the target.

9.2.3.3.1 Protection Region

Two types of regions are distinguished in a target firewall (see [Figure 9-4](#)):

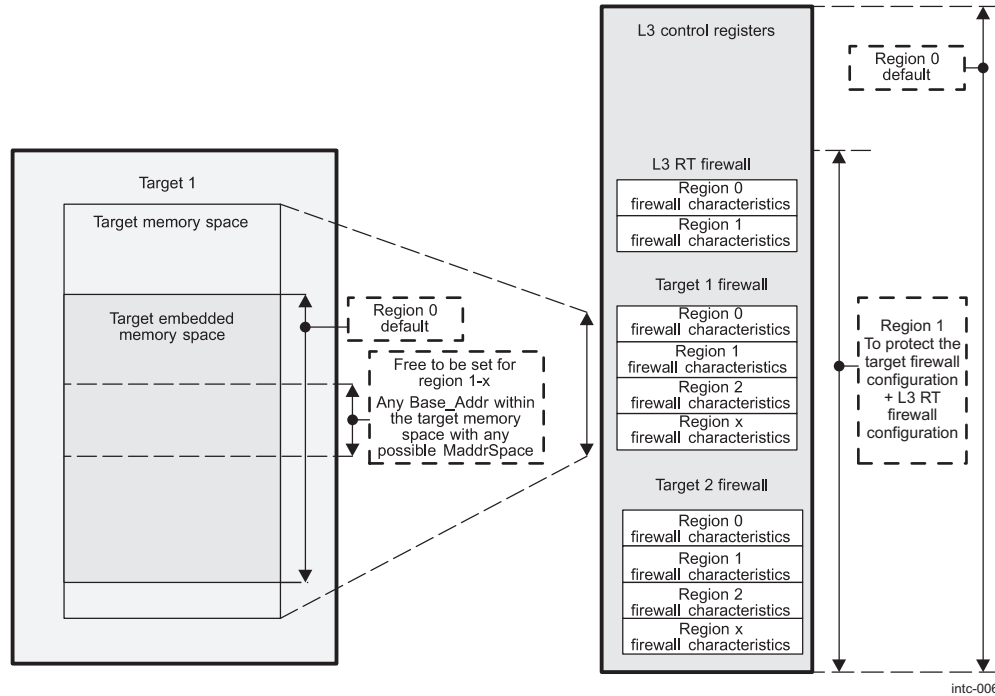

- Default region: Available in all targets; spans the entire target address range
- Normal region: Number varies in a target; they have identical capabilities

Each region has the following characteristics:

- A base address, relative to the target address itself, and an address space

- A size
- Specific access rights, as defined through the MReqInfo qualifiers
- A priority level, from 0 (lowest) to 3 (highest)

Figure 9-4. L3 Firewall Implementation

9.2.3.3.1.1 Default Region/Region0

Region 0 is the default region of a whole target; it spans the entire target address space.

The default region is always the lowest priority. This region is systematically overlapped when other regions are set.

The [L3_PM_ADDR_MATCH_k](#) register is not accessible. Its configuration corresponds to all the possible addresses for the target, including all of ADDR_SPACE. It is not possible to program multiple ADDR_SPACE addresses in a normal region.

9.2.3.3.1.2 Normal Regions

Normal regions have identical features.

A given request either maps into a specific protection region or is considered to have hit the default protection region if no normal region is hit.

The protection regions can only be configured for a memory space that is power-of-two in size and size-aligned using the SIZE bit field [L3_PM_ADDR_MATCH_k \[7:3\]](#) (as listed in [Table 9-21](#)). When the SIZE bit field [L3_PM_ADDR_MATCH_k \[7:3\]](#) is set to 0, the region is disabled.

NOTE: k denotes the region number. Depending on the target, n varies from 0 to 7.

[Table 9-21](#) lists the size encoding for each value set in the SIZE bit field.

Table 9-21. L3 Firewall Size Parameter Definition

Possible Configuration		
Size ⁽¹⁾	Region Size	Base_Addr ⁽²⁾
0x0	Region disabled	Any (nonsignificant)
0x1	1K-byte	0x0000000
		0x0000400
		0x0000800
		.
0x2	2K-byte	0x0000000
		0x0000800
		0x0001000
		...
...
0x17	2 ^{^(17-1)} K-byte	
Others	Not allowed	-

⁽¹⁾ When the size parameter is set to 0, the region is disabled.

⁽²⁾ The base address depends on user settings.

9.2.3.3.2 Priority Level Overview

Each L3 firewall region is prioritized. Depending on its priority level, a region can override the settings of another region.

- Region 0 is the only allowed priority 0 region (lowest priority).
- Region 1 is the only allowed priority 3 region (highest priority).
- Others regions are defined as priority 1 or 2.

CAUTION

LEVEL bitfield value of ADDR_MATCH_1 register (Region 1 firewall configuration) must be kept to his default reset value and must not be changed; otherwise, the result will be unpredictable and can create unexpected protection holes or denial of service.

Protection level is defined by the LEVEL bit [L3_PM_ADDR_MATCH_k](#) , where n is greater than 2. [Figure 9-5](#) represents the priority level with associated regions.

When an address hits two or more regions with different priority levels, the highest priority region protections are applied. The overlay region can overlap all or a part of a nonoverlay region.

CAUTION

Configuring two overlapping protection regions with the same priority level leads to undefined behavior.

Hardware behavior in the case of overlapping protection regions is undefined. A region with higher priority must be used to mask a region that is being reprogrammed, and any protection holes must be avoided during this reconfiguration.

To change the protection settings of a region, follow this procedure:

1. Ensure that a free region is available to be used as a high-priority region.

2. Program this region as a high-priority region so its parameters match the region to be changed. The final programming must be the [L3_PM_ADDR_MATCH_k](#) register, which includes the priority attribute and the size parameter to enable the region.
3. Disable the region to be configured or reconfigure it by setting the SIZE bit field to 0.
4. Set up all region control registers with the new configuration. The final programming must be the [L3_PM_ADDR_MATCH_k](#) register, which includes the size parameter to enable the region.
5. Disable the high-priority region by setting its size to 0.

This procedure must be used each time there is an overlap between the originally defined region and the newly defined region. The use of a high-priority region is required to keep protection active during programming.

Figure 9-5. L3 Region Overlay and Priority Level Overview

intc-001

9.2.3.3.3 Read and Write Permission

Read permission and write permission are configured using two registers:

- [L3_PM_READ_PERMISSION_i](#)
- [L3_PM_WRITE_PERMISSION_i](#)

The [L3_PM_READ_PERMISSION_i](#) and [L3_PM_WRITE_PERMISSION_i](#) registers allow the setting of read and write permission to one or more initiators. To grant read or write access, set the bit associated with the initiator to 1.

9.2.3.3.4 REQ_INFO_PERMISSION Configuration

The firewall comparison mechanism enables access to a protected target only when a correct combination of four MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 3-bit pattern that corresponds to a combination of the parameters MReqDebug, MReqType, and MReqSupervisor.

Different valid MReqInfo combinations can be defined for each L3 firewall region based on the [L3_PM_REQ_INFO_PERMISSION_i](#) value, which is programmed by software.

For each region, [L3_PM_REQ_INFO_PERMISSION_i](#) lists the possible MReqInfo combinations. Setting a Reqbit in this register determines the type of access authorized to the initiator.

[Table 9-22](#) lists the MReqInfo combinations available and the Reqbit associated with it.

Table 9-22. MReqInfo Parameter Combinations

Reqbit	MReqInfo		
	MReqSupervisor	MReqDebug	MReqType
0	User	Functional	Data
1	User	Functional	Code
2	User	Debug	Data
3	User	Debug	Code
4		Reserved for non-GP devices	
5		Reserved for non-GP devices	
6		Reserved for non-GP devices	
7		Reserved for non-GP devices	
8	Supervisor	Functional	Data
9	Supervisor	Functional	Code
10	Supervisor	Debug	Data
11	Supervisor	Debug	Code
12		Reserved for non-GP devices	
13		Reserved for non-GP devices	
14		Reserved for non-GP devices	
15		Reserved for non-GP devices	

[Figure 9-6](#) shows an example of the [L3_PM_REQ_INFO_PERMISSION_i](#) setting. In this example, [L3_PM_REQ_INFO_PERMISSION_i](#) is set to 0x0C05 (16'b0000_1100_0001_0101) for a specific region, which will grant access only if the request:

- User + Functional + Data
- User + Debug + Data
- Supervisor + Debug + Data
- Supervisor + Debug + Code

Figure 9-6. Example of REQ_INFO_PERMISSION Register

As another example, to configure a target accessible only for data and in a user mode, Reqbit 0, 1, 2 and 3 must be set. Therefore, the `L3_PM_REQ_INFO_PERMISSION_i` register must be set to 0x000F.

9.2.3.3.5 L3 Firewall Registers Overview

Table 9-23 lists the L3 firewall permission-setting registers. `L3_PM_ADDR_MATCH_k`, which is shown in this table, is not an accessible register.

Table 9-23. L3 Firewall Permission-Setting Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments	Region Comments
Region 0				
<code>L3_PM_ADDR_MATCH_k</code> (k=0)	ADDR_SPACE[2:0]	Hard coded	Corresponds to all the target memory space	This region is the default region. The default setting can be changed only with correct access according to L3 RT register.
	SIZE[7:3]	Hard coded	Corresponds to all the target memory space	
	Reserved		Default region: Level 0	
	BASE_ADDR[63:10]	Hard coded	Target-dependent	
<code>L3_PM_REQ_INFO_PERMISSION_i</code> (i=0)	REQ_INFO[15 :0]	Yes	Type of access permitted. See Table 9-22.	
<code>L3_PM_READ_PERMISSION_i</code> (i=0)	READ_PERMISSION[15:0]	Yes	Initiator read permission, depending on connections. See Table 9-14.	
<code>L3_PM_WRITE_PERMISSION_j</code> (i=0)	WRITE_PERMISSION[15 :0]	Yes	Initiator write permission, depending on connections. See Table 9-14.	

Table 9-23. L3 Firewall Permission-Setting Registers (continued)

Register Name	Register Field Name	Field Modifiability	Parameter Comments	Region Comments
Region 1-7				The default settings can be changed only with correct access based on the L3 RT register.
L3_PM_ADDR_MATCH_k	ADDR_SPACE[2:0]	Yes		
	SIZE [7:3]	Yes	The regions are power-of-two in size and size-aligned with Base_Addr reference. When Size = 0x0, the firewall is deactivated.	
	LEVEL[9]	Yes	Protection region level 0x0: Level 1 0x1: Level 2 Region 1 is always Level 3.	
	BASE_ADDR[63:10]	Yes	Target-dependent	
L3_PM_REQ_INFO_PERMISS ION_i	REQ_INFO[15 :0]	Yes	Type of access permitted. See Table 9-22 .	
L3_PM_READ_PERMISSION_i	READ_PERMISSION[15:0]	Yes	Initiators read permission ,depending on connections. See Table 9-14 .	
L3_PM_WRITE_PERMISSION_j	WRITE_PERMISSION[15 :0]	Yes	Initiators write permission, depending on connections. See Table 9-14 .	

9.2.3.3.6 L3 Firewall Error-Logging Registers

[Table 9-24](#) lists the L3 firewall error-logging registers.

Table 9-24. L3 Firewall Error Logging Registers

Register Name	Register Field Name	Field Modifiability	Parameter Comments
L3_PM_ERROR_LOG	CMD[2:0]	Read only	Log the OCP command of the request that caused a protection violation. See Table 9-1 .
	REGION[6:4]	Read only	Log the region number targeted by the request that caused the protection violation.
	INITIATOR_ID[15:8]	Read only	Log the InitiatorID request that caused the protection violation. See Table 9-19
	REQ_INFO[20:16]	Read only	Log the MReqInfo bits of the request that caused the protection violation. See Table 9-22 .
	CODE[27:24]	Read/write	Log the error that occurred. See Table 9-26 .
	MULT[31]	Read/write	If a second error is detected before the first is cleared, the MULT bit is set. Once set by hardware, the CODE and MULT bits can be cleared only by software or a full hardware reset. Software clears the CODE and MULT bits by writing a non-zero value to the CODE field and writing 1 to the MULT bit.

9.2.3.3.7 L3 Firewall and System Control Module

When a protection violation occurs, an interrupt is sent to the MPU and IVA2.2 interrupt controller (if enabled). An in-band error is sent back, and an out-band error is logged in the CONTROL.CONTROL_PROT_ERR_STATUS register. Two logging registers are used, depending on the functional mode:

- In application mode:
 - CONTROL.CONTROL_PROT_ERR_STATUS [00]: OCM-ROM protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS [01]: OCM-RAM protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS [02]: GPMC protection violation

- CONTROL.CONTROL_PROT_ERR_STATUS [04]: SMS protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [05]: MAD2D protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [06]: IVA2.2 protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [07]: L4-Core protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [12]: L3 RT protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [15]: SAD2D protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [16]: L4-Per protection violation
- CONTROL.CONTROL_PROT_ERR_STATUS [17]: L4-Emu protection violation
- In debug mode:
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [00]: OCM-ROM protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [01]: OCM-RAM protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [02]: GPMC protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [03]: SMS protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [05]: MAD2D protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [06]: IVA2.2 protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [12]: L3 RT protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [16]: L4-Per protection violation
 - CONTROL.CONTROL_PROT_ERR_STATUS_DEBUG [17]: L4-Emu protection violation

When a violation occurs, these bits are cleared when the L3 or L4 firewall embedded error log registers are cleared.

9.2.3.4 Error Handling

9.2.3.4.1 Error Detection and Logging

The L3 interconnect provides mechanisms for the detection, logging, and distribution of module-detected and internal interconnect errors. Hardware support is provided to assist in logging errors and cleaning up the state to allow error recovery software to run.

Two types of errors are identified by the L3 interconnect:

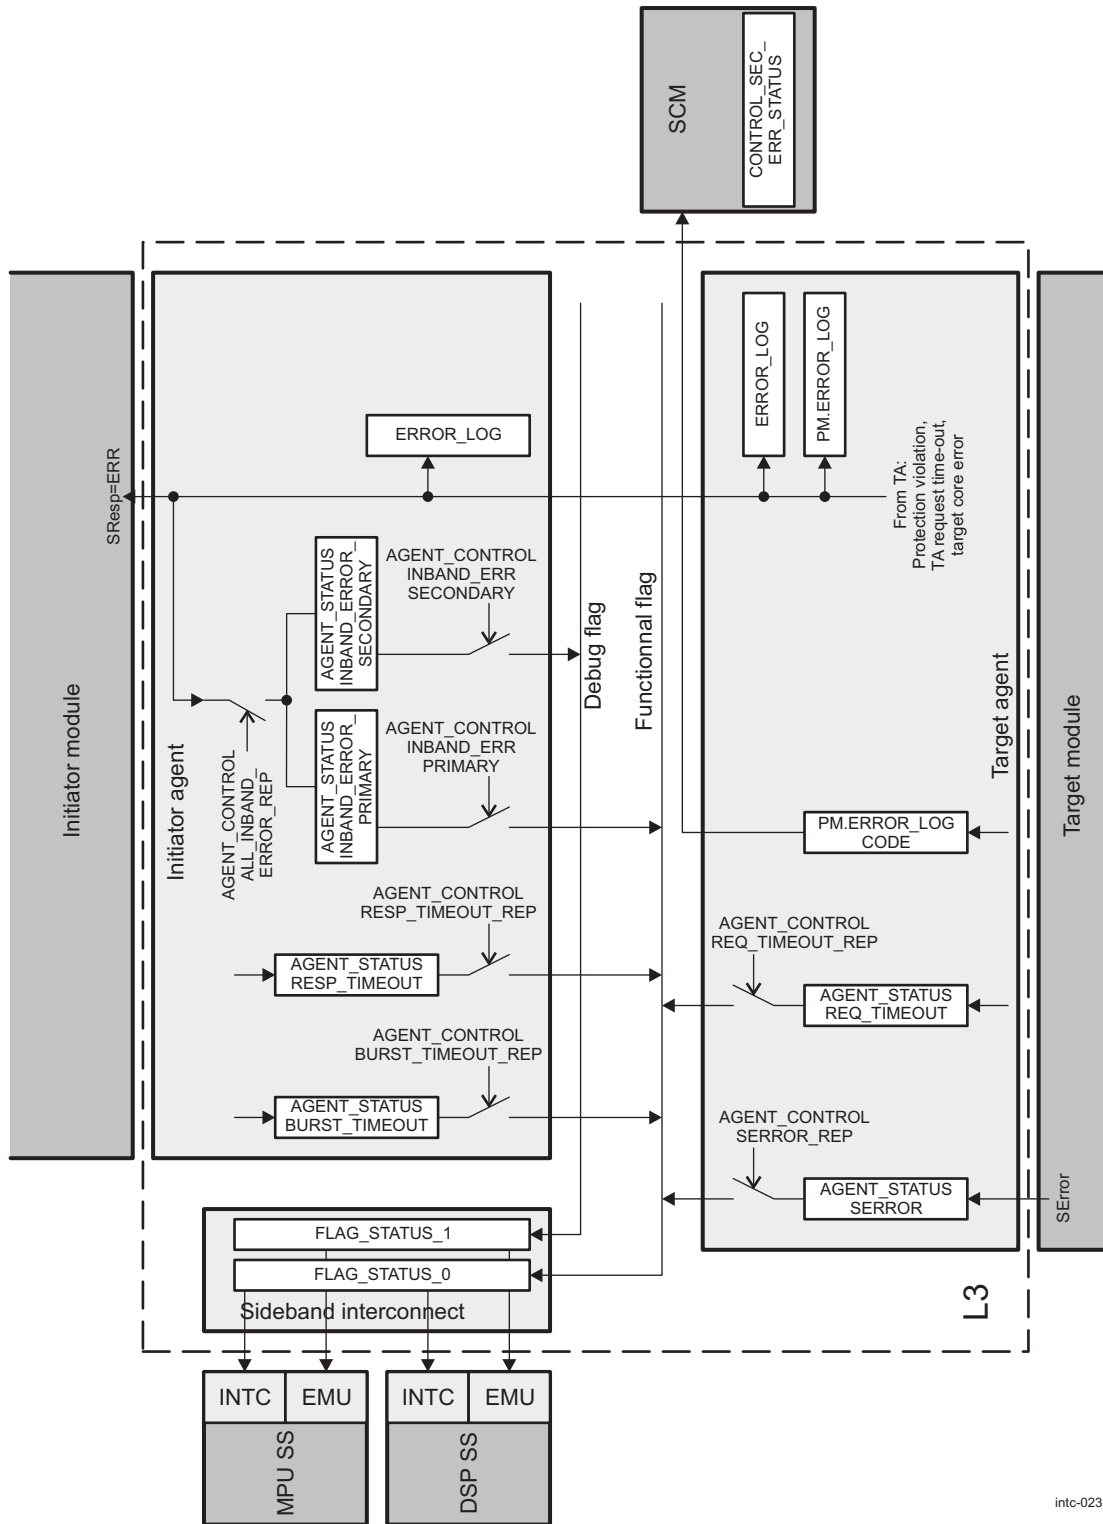

- Errors detected by modules and passed along by the interconnect:
 - SResp error: Using the SResp in-band qualifier from the target, the initiator is informed that its request was unsuccessful (see [Table 9-3](#)). This error is nonspecific and further analysis is required to find its cause.
 - SError: This out-of-band qualifier reports that the target is denied service due to an internal cause. No further analysis can be done in the L3 itself.
- Errors detected by the L3 interconnect:
 - Unsupported command: This error reports that the initiator sent a command that cannot be processed, because the target cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
 - Address hole: This error reports an unknown address for a request. The address map is local to each IA; therefore, an address hole error is reported each time an initiator requests an access to a target it is not logically connected to, even if this address exists in the global L3 address map. This error is detected only once per burst.
 - Protection violation: This error indicates a request was rejected by a firewall.
 - Requests time-out: This error reports that the target did not accept (if no response expected) or did not respond to the request presented by the interconnect TA. In this case, all new requests to this TA will be answered with SResp = ERR.
 - Response time-out: This error reports that the initiator did not accept response from the interconnect IA in the correct time interval (applies only to masters that have response flow control capabilities). In this case, the IA sends burst close transactions to TAs that have open transactions

from this IA. Any new request from this initiator is refused.

- Burst open time-out: This error reports that a burst or ReadEx/Write pair has been started to the interconnect IA by the initiator but did not finish in the correct time interval. If the time interval for any command exceeds the time-out period, a time-out occurs. The initiator does not complete a burst or ReadEx/Write pair. The interconnect IA then closes the transaction by a burst close transaction, to allow traffic from other initiators to resume. Burst close is logged in the interconnect TA when received.

[Figure 9-7](#) shows a global view of the register link to the error reporting structure in an initiator and the target agents.

Figure 9-7. L3 Error Reporting Structure

intc-023

Most errors are reported to the IA that originated the request, except for the following:

- Initiator time-outs are reported only out-of-band. Any time-out in the IA results in flagging it as unavailable. A software reset of the agent is required to accept any new requests from the attached core.

- Posted write request, because the IA immediately generates a valid response to the initiator core. This error is only in out-of-band.

Table 9-25 lists where the errors are detected and logged.

Table 9-25. Error Types

Error	Detection	Logging	In-Band Report	Out-of-Band Report
SResp error	None needed	At IA	Yes ⁽¹⁾	Yes
SError assertion from target	None needed	At TA	No	Yes
Unsupported command	At IA	At IA	Yes	Yes
Address hole	At IA	At IA	Yes	Yes
Protection violation	At TA	At protection mechanism agent	Yes ⁽¹⁾	Yes
Response time out	At IA	At TA	No	Yes
Request time-out	At TA	At IA	No	Yes
Burst time-out	At IA	At IA	No	Yes

⁽¹⁾ In case of a posted write, errors cannot be reported in-band.

The time-out errors (request/response and burst) are persistent and require the software to reset both the module and the agent. No request can be processed in the agent until the reset is performed.

Other errors affect only the current request. Subsequent requests are treated normally. Errors are logged, however, and the information about the error used for debugging is kept until the software acknowledges the error.

Table 9-26 lists the information logged for each error code. Information logged in the two error-logging registers (L3_IA_ERROR_LOG, L3_IA_ERROR_LOG_ADDR, L3_TA_ERROR_LOG and L3_TA_ERROR_LOG_ADDR for each IA and TA) depends on the error itself. The CODE field ERROR_LOG[27:24] identifies the type of error occurring for the IA and TA.

Table 9-26. CODE Field Definition

CODE[3:0]	Error Type	Type of Agent			Information Logged				
		IA	TA	PM	REQ_INFO	Secondary	InitiatorID	CMD	Address
0	No error	x	x						
1	Unsupported command	x			x	x	x	x	x
2	Address hole	x			x	x	x	x	x
3	Protection violation			x	x		x	x	
4	In-band error	x				x	x		
5	Not used								
6	Not used								
7	Request time-out not accepted		x		x		x	x	x
8	Request time-out, no response		x				x		
9-15	Not used								

9.2.3.4.2 Time-Out

A time-out mechanism can be enabled in the target agent and initiator agent register. When the mechanism is enabled for a target agent or initiator agent and commands are not accepted or responses are not returned within the expected delay, the L3 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit [L3_TA_AGENT_STATUS\[8\]](#) for a target agent time-out, the BURST_TIMEOUT bit [L3_IA_AGENT_STATUS\[16\]](#) bit for an initiator burst time-out, and the RESP_TIMEOUT bit [L3_IA_AGENT_STATUS\[8\]](#) for an initiator response time-out. The affected agent enters an error state that causes it to send error responses to any new request. To recover from this state, the target agent must be reset by system software.

The time-out is counted starting from the moment a command is presented to the target, whatever the target response to this command is. The L3 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected target agents. These four signals are referred to as 1x time-base, 4x time-base, 16x time-base, and 64x time-base.

The time-base circuit offers four possible sets of four time-base signals selected by programming the TIMEOUT_BASE field [L3_RT_NETWORK_CONTROL\[10:8\]](#). [Table 9-27](#) lists all of the values in the number of L3 clock cycles.

Each target agent can be programmed to refer to one of the four time-base signals. A time-out condition is detected when either the command acceptance or the response is not received after a delay of between one and three time-base periods. After the time-out is detected and logged, the behavior of the attached module is ignored. A new request to the module arriving at the timed-out target agent receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module using its internal soft-reset bit, and then the agent using software reset.

Table 9-27. L3 Timeout Register Target and Agent Programming

REQ_TIMEOUT[2:0], BURST_TIMEOUT[2:0], and RESP_TIMEOUT[2:0]					
TIMEOUT_BASE[2:0]	0	1	2	3	4
0	All L3 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

9.2.3.4.3 Error Steering

The error reporting structure consist of errors logged individually in the initiator or TAs. Some errors can be enabled and reported out-of-band by setting the following bits to 1:

- [L3_IA_AGENT_CONTROL.BURST_TIMEOUT_REP](#) bit for burst time-out
- [L3_IA_AGENT_CONTROL.RESP_TIMEOUT_REP](#) bit for response time-out
- [L3_TA_AGENT_CONTROL.REQ_TIMEOUT_REP](#) bit for request time-out
- [L3_TA_AGENT_CONTROL.SERROR_REP](#) bit for request time-out

Setting the [L3_IA_AGENT_CONTROL.ALL_INBAND_ERROR_REP](#) bit causes all in-band errors returned to the IA to be reported out-of-band.

IAs connected to processors capable of generating the debug-flagged requests (the MPU and IVA2.2 subsystems) use error steering. Any error linked to an application (nondebug) request is qualified as primary; any error linked to a debug request is qualified as secondary. Setting the [IA.INBAND_ERROR_PRIMARY_REP](#) or [INBAND_ERROR_SECONDARY_REP](#) bit to 1 allows the reporting of in-band to out-of-band primary and secondary errors.

The level of the current error is indicated in SECONDARY bit [L3_IA_ERROR_LOG\[30\]](#). If an error occurs while another error is pending, the following occurs:

- If the pending error is primary, the new error is discarded at the IA level. MULTI bit [L3_IA_ERROR_LOG\[31\]](#) is set in the initiator error log register to indicate that another error has been detected; no further information can be stored.
- If both the pending error and the new error are secondary, the latest error is discarded and MULTI bit [L3_IA_ERROR_LOG\[31\]](#) is set.

- If the pending error is secondary and the incoming error is primary, MULTI bit [L3_IA_ERROR_LOG](#)[31] is set and all useful information about the new error (MCmd, MAddr, MReqInfo, etc.) is stored. All information relative to the secondary error is discarded.

For protection violation, errors are detected at the TA and steered to the control module (see [Section 9.2.3.3.7, L3 Firewall and System Control Module](#)).

9.2.3.4.4 Global Error Reporting

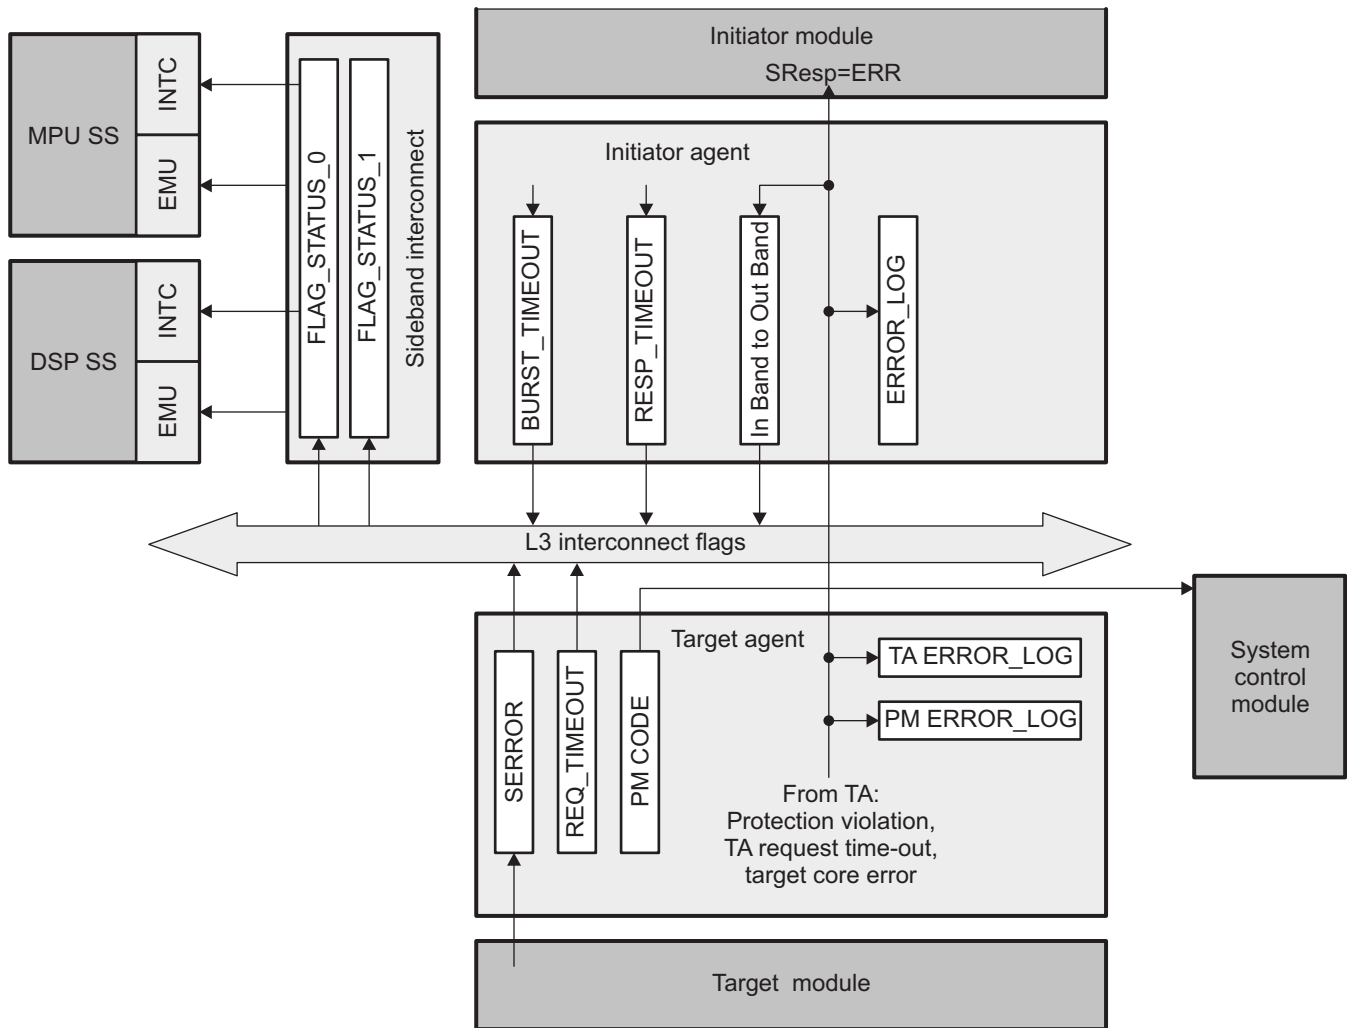

An out-of-band error refers to any flag output from the L3. It is not a formal error in the sense that it is not processed directly by the interconnect module; however, it is interpreted as such by one or several processors, typically by mapping it to an interrupt controller. All L3 out-of-band errors are ORed together and the result is transmitted to one or several interrupt controllers. All out-of-band errors are active high and must be acknowledged through a register access to be deasserted.

Out-of-band errors are reported through error or flag signals, asynchronously to any other data flow, but synchronously to the clock.

All errors are reported out-of-band to the IVA2.2 and MPU subsystems simultaneously. The processors must check whether an error is relevant to the subsystems. These errors are routed not only to the IVA2.2 and MPU subsystem interrupt controllers, but also to their emulation logic (see [Figure 9-8](#)). Two composite flags help in asserting the error origin and criticality:

- The L3 application error flag reports application or nonattributable (not related to a request such as a time-out, SError) errors.
- The L3 debug error flag reports debug errors.

Figure 9-8. Global Error Routing

intc-011

In addition to the SResp qualifier error reporting, some external targets use an SError signal to indicate that an internal error has occurred. Some resetting action may be required before any new request can be accepted, depending on the module and on the error itself. These signals are routed as flags internally to the L3. Table 9-28 lists the possible errors reported through an SError, propagated externally to the L3 interconnect, and aggregated to the L3 application error flag.

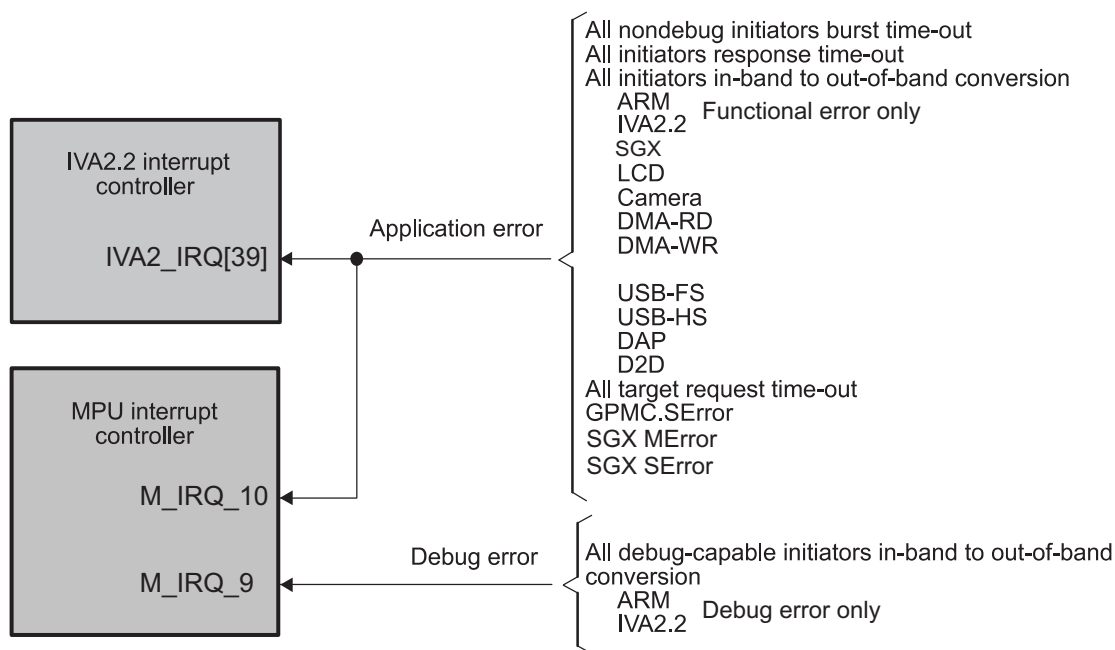

Table 9-28. L3 External Input Flags

Target	Flag	Description	Software Visible?
GPMC	SError	General-purpose error occurs in GPMC module	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]
SGX master	MError	General-purpose error occurs in SGX master	Yes, in FLAG_STATUS register and in L3 IA MERROR bit AGENT_STATUS[24]
SGX target	SError	General-purpose error occurs in SGX target	Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24]

NOTE: The user must ensure that the corresponding IRQ lines are set correctly in the interrupt controllers of the MPU and IVA2.2 subsystems.

Figure 9-9 shows the routing of errors to the application and debug error composite flags. Because both debug capable processors, the MPU and IVA2.2 subsystems have access to the full error report mechanism; they can be debugged independently of one another.

Figure 9-9. L3 Error Routing

interconnect-005

Table 9-29 lists the bit and source for the STATUS bit field [L3_SI_FLAG_STATUS_0\[63:0\]](#) for an application error, and Table 9-30 lists the bit and source for the STATUS bit field [L3_SI_FLAG_STATUS_1\[63:0\]](#) for an application error for a debug error.

Protection errors are reported in-band to the IA when possible. This may not be possible for posted writes, however. These errors are also reported asynchronously to the module.

Additionally, all protection errors (even posted writes) are seen by the in-band-to-out-of-band conversion logic in the IAs. Therefore, all protection errors feed into the L3 application error and L3 debug error composite flags, and hence back to the MPU and IVA2.2 subsystems.

The SMS, L4-Core, L-4 Per, and L4-Emu interconnects have internal firewalls that use the same reporting scheme. These errors are not routed directly to the L3 interconnect but are reported in-band to the initiator, which routes them to the composite flags. The SMS, L4-Core, L4-Per, and L4-Emu interconnects always provide an error on the in-band SResp qualifier for protection violations.

Table 9-29. L3_SI_FLAG_STATUS_0 for Application Error

Flag Bit Number	Source		Flag Bit Number	Source	
	Agent	Error		Agent	Error
0	MPU IA	Burst time-out	32	Reserved

9.2.4 L3 Interconnect Basic Programming Model

9.2.4.1 General Recommendation

The L3 interconnect registers must be read or written with little-endian attributes; otherwise, the result is undefined.

CAUTION

Overlapping between protection regions with the same priority level leads to unpredictable behavior and must be avoided.

9.2.4.2 Initialization

At the release of power on reset, the L3 firewall default configuration enables all accesses to target modules, except for a section of the OCM ROM.

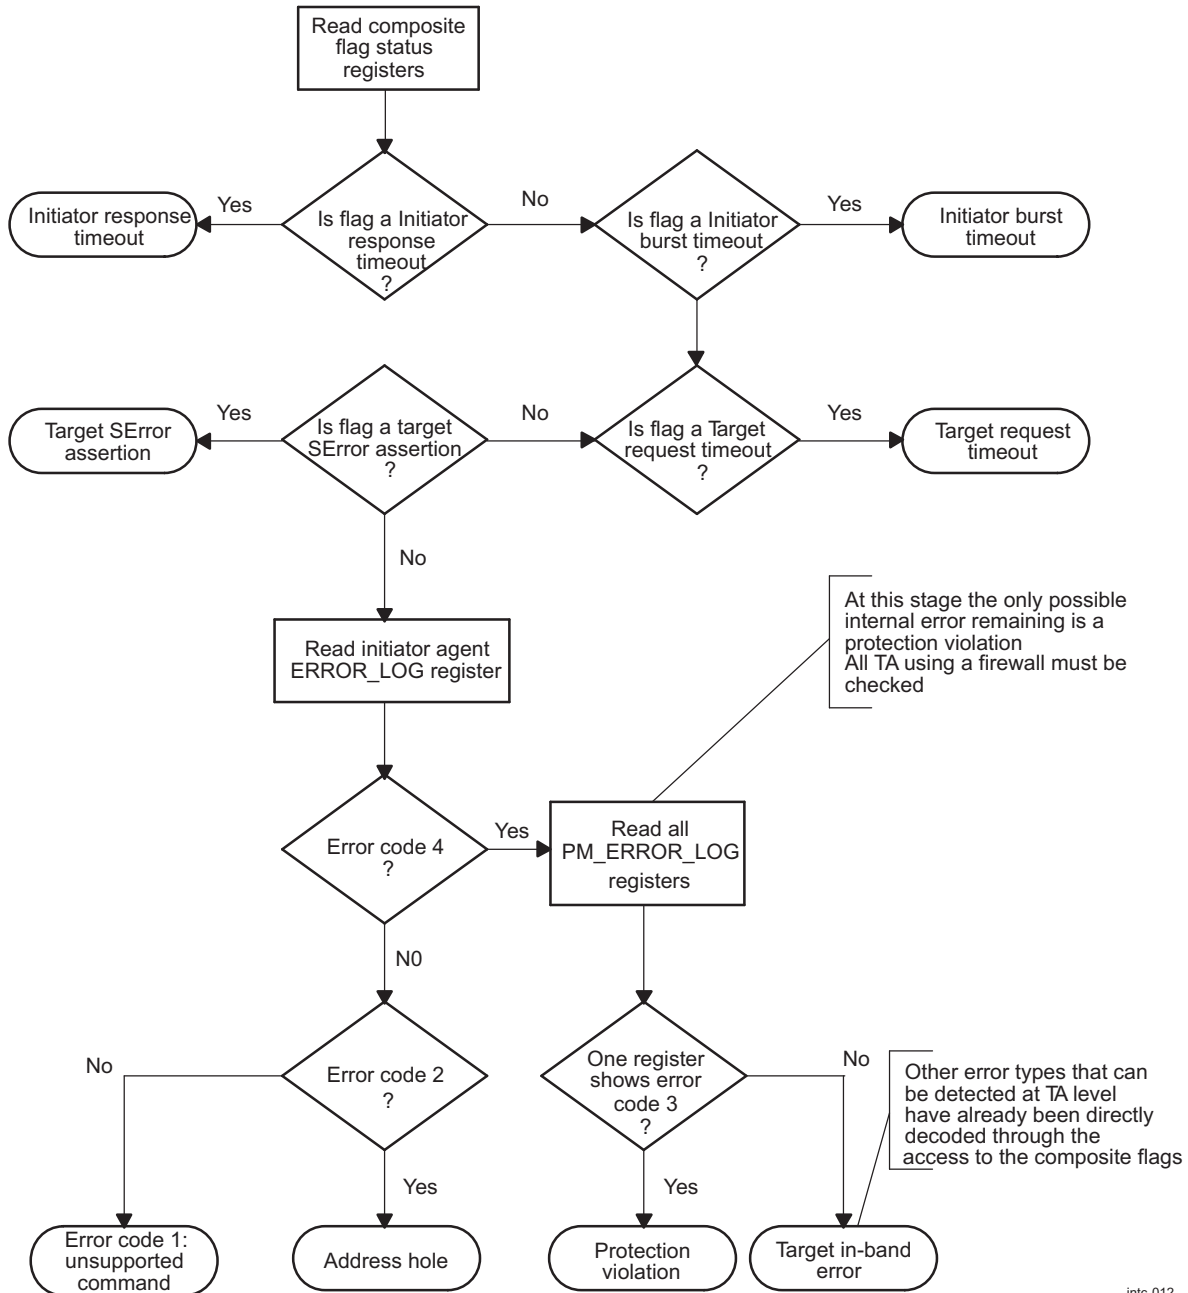

Generally, software must configure the firewall properly to avoid poor use of the hardware resources.

L3 time-out capabilities are also disabled at reset.

9.2.4.3 Error Analysis

The information required to analyze an error source is logged in several registers (see [Table 9-26](#)). The number of registers to access depends on the error source. When investigating the origin of an error, software reads a set of error log registers. At each stage, the register either states the current error or points to the next agent in which the error is logged. [Figure 9-10](#) shows the software sequence required in most cases.

Figure 9-10. Typical Error Analysis Sequence

intc-012

Errors that do not result from an in-band to out-of-band conversion can be extracted immediately from the application or debug error flag by reading the STATUS field [L3_SI_FLAG_STATUS_0\[63:0\]](#) and [L3_SI_FLAG_STATUS_1\[63:0\]](#) register; therefore, they do not require the whole analysis sequence shown in [Table 9-26](#).

When analysis leads to a TA error, software must read the initiator agent ADDR field [L3_IA_ERROR_LOG_ADDR\[39:0\]](#) to extract the TA address causing the error.

9.2.4.3.1 Time-Out Handling

This section gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Example 1

In this example, the MPU interrupt handler detects an error from the L3 interconnect. A read access from the [L3_SI_FLAG_STATUS_0](#) register reports a value of 0x40000. As described in [Table 9-29](#), the error detected is a burst time-out from the sDMA read port.

As with any time-out error, the affected module is now considered to be out-of-service. If necessary, the error can be cleared by sending a soft reset command to the agent (set `CORE_RESET` bit [L3_IA_AGENT_CONTROL\[0\]](#) to 1, and then to 0). During this time the initiator is off-line. Although the rest of the system still behaves normally, a time-out error is usually severe enough to require a complete reset of the chip.

Before resetting the agent or the system, the error log registers can learn the status of the interconnect and determine the type of failure. Reading the `IA_SDMA_RD.L3_IA_AGENT_STATUS` register shows whether the time-out was detected during a burst or during a read/write sequence.

Example 2

In this example, the MPU interrupt controller detects an error from the L3 interconnect. A read access from the [L3_SI_FLAG_STATUS_0](#) register reports a value of 0x100. This is a functional error from the IVA2.2 subsystem initiator.

The `IA_IVA2.2.L3_IA_ERROR_LOG` register should be read next. The value stored in it is 0x12_0400_1302.

- `CMD` field `IA_IVA2.2.L3_IA_ERROR_LOG[2:0]`: Value 0x2. Not applicable for an in-band error.
- `INITID` field `IA_IVA2.2.L3_IA_ERROR_LOG[15:8]`: Value 0x13. The origin of the error is the IVA2.2 subsystem sDMA.
- `CODE` field `IA_IVA2.2.L3_IA_ERROR_LOG[27:24]`: Value 0x4. Error is an in-band error.
- `SECONDARY` bit `IA_IVA2.2.L3_IA_ERROR_LOG[30]`: Value 0x0. The error is functional.
- `MULTI` bit `IA_IVA2.2.L3_IA_ERROR_LOG[31]`: Value 0x0. No additional error has been detected.
- `REQ_INFO` field `IA_IVA2.2.L3_IA_ERROR_LOG[43:32]`: Value 0x12. Not applicable for an in-band error.

There is no simple way to determine which target originated the in-band error. An SError assertion or a request time-out would have been detected and logged in the [L3_SI_FLAG_STATUS_0](#) register. Because no such error is asserted (bits 60:48 are still 0), the error can only be a firewall error or have originated in the target itself. The user must read all of the `PM_xxx.L3_PM_ERROR_LOG` registers.

CAUTION

The PM register blocks are sensitive registers and are usually protected. Ensure that the processor used to debug the error is allowed to access these registers. If not, the access will be rejected and another error will be generated.

All `PM_xxx.L3_PM_ERROR_LOG` registers are clear (bits 27:24 equal 0x0) except for `PM_OCMRAM.L3_PM_ERROR_LOG`, which reads 0x0302_1301. The error occurred while trying to access the OCM RAM.

NOTE: If all `PM_xxx.L3_PM_ERROR_LOG` registers are clear, the error is unrelated to the interconnect. Further analysis must be done in the targets.

- Bits 27:24: Value 0x3. There is a protection error.
- Bits 2:0: Value 0x1. The command was a posted write.
- Bits 6:4: Value 0x0. The address is protected by Region 0 (default region) of the firewall.
- Bits 15:8: Value 0x13. The origin of the error is the IVA2.2, thread 2. This is consistent with the error log on the initiator side, and confirms this error report is the correct one.
- Bits 20:16: Value 0x2. The protection parameters were data, debug, and user.
- Bit 31: Value 0x0. This is the only error detected.

A check on the protection configuration confirms that this access was not allowed, either because the initiator was not given write access or because the protection access parameters were not compatible with the PM_OCMRAM.REQINFO_PERMISSIONS_0 settings.

A protection violation is not terminal from the interconnect point of view. If the module responsible for the global chip protection do not reset the system (including the IVA2.2 subsystem and the OCM RAM), it continues to run normally. A simple clearing of the error on both the IA and PM sides is required to return to a clean status.

9.2.4.3.2 Acknowledging Errors

Time-out errors can never be acknowledged. To return to a normal operation after an error, the faulty agent must be reset . An agent can be reset by asserting CORE_RESET bit [L3_IA_AGENT_CONTROL\[0\]](#) or [L3_TA_AGENT_CONTROL\[0\]](#), or by resetting the L3 interconnect through the PRCM.

Functional errors, including an in-band signal reporting a protection error, must be inactivated through software. Setting the INBAND_ERROR_PRIMARY and INBAND_ERROR_SECONDARY bits [L3_IA_AGENT_STATUS\[28-29\]](#) in an IA, or setting the SERROR bit [L3_IA_AGENT_STATUS\[24\]](#) in a TA clears the reported error. [Table 9-31](#) lists the bit to clear and the associated type of error.

The [L3_IA_ERROR_LOG](#) or [L3_TA_ERROR_LOG](#) register must also be cleared by writing a nonzero value simultaneously to the CODE bit field and the values currently stored in the MULTI and SECONDARY fields.

Table 9-31. Error Clearing

Agent Type	Error	Register Field
Initiator	In-band primary (application) error	INBAND_ERROR_PRIMARY
	In-band secondary (debug) error	INBAND_ERROR_SECONDARY
Target	Target asserts SError	SERROR

The procedure to clear protection errors depends on the system protection configuration:

- Write a nonzero value simultaneously into CODE bit field [L3_PM_ERROR_LOG\[27:24\]](#) and the value currently stored in the MULTI bit [L3_PM_ERROR_LOG\[31\]](#) of the corresponding PM register block.
- Alternately, read either [L3_PM_ERROR_CLEAR_SINGLE](#) or [L3_PM_ERROR_CLEAR_MULTI](#), depending on the current value of the MULTI field in the [L3_PM_ERROR_LOG](#) register. This solution, which allows the clearing of protection errors without having a write access on other protection registers, preserves protection.

[L3_SI_FLAG_STATUS_0](#) or [L3_SI_FLAG_STATUS_1](#) must be checked at the end of any error acknowledging sequence to confirm that the acknowledgement was successful and that no other error is pending.

9.2.4.4 Typical Example of Firewall Programming Example

All four regions in the IVA2.2 target firewall can be configured with no restrictions. However, protection is required for a 14K-byte region starting at address 0x0 in address space 2, and it must accept any access from any initiator for the rest of the target. The protection restricts allowed accesses as follows:

- Only the IVA2.2 and the MPU can read from this memory.
- Only the MPU can write to this memory.
- The protection parameters must include supervisor and functional.

Only accesses declared as supervisor and functional are allowed to pass through the protected region of the firewall. There is no restriction on other attributes.

Table 9-32 lists the possible parameter combinations, whether they are allowed to pass or not, and why they are rejected.

Table 9-32. MReqInfo Parameter Example

Reqbit	MReqInfo				
	MReqSupervisor	MReqDebug	MReqType	Access Allowed	Reason for Rejection
0	User	Functional	Data	No	Not supervisor
1	User	Functional	Code	No	Not supervisor
2	User	Debug	Data	No	Not supervisor
3	User	Debug	Code	No	Not supervisor
4		Reserved for non-GP devices		No	
5		Reserved for non-GP devices		No	
6		Reserved for non-GP devices		No	
7		Reserved for non-GP devices		No	
8	Supervisor	Functional	Data	Yes	
9	Supervisor	Functional	Code	Yes	
10	Supervisor	Debug	Data	No	Not functional
11	Supervisor	Debug	Code	No	Not functional
12		Reserved for non-GP devices		No	
13		Reserved for non-GP devices		No	
14		Reserved for non-GP devices		No	
15		Reserved for non-GP devices		No	

Only combinations with codes 8 and 9 are allowed to access a target. REQ_INFO field PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i[15:0] for the protected region must be set to (0x8) | (0x9); that is, 0x0300.

Solution 1

Set Region 0 to accept all accesses:

- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=0)= 0xFFFF
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=0)= 0x140E
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=0)= 0x140E

Set Region 1 to cover the first 8K bytes of the protected region:

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=1) = 0x22 (start address 0x0, size 8K bytes, address space 2)
- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=1) = 0x0300
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=1) = 0x0406 (IVA2.2 DMA and MMU and MPU are allowed)
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=1) = 0x0002 (only MPU is allowed to write)

Set Region 2 to cover the next 4K bytes:

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=2) = 0x201A (start address 0x2000, level 1, size 4K bytes, address space 2)
- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=2) = 0x0300
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=2) = 0x0406
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=2) = 0x0002

Set Region 3 to cover the last 2K bytes:

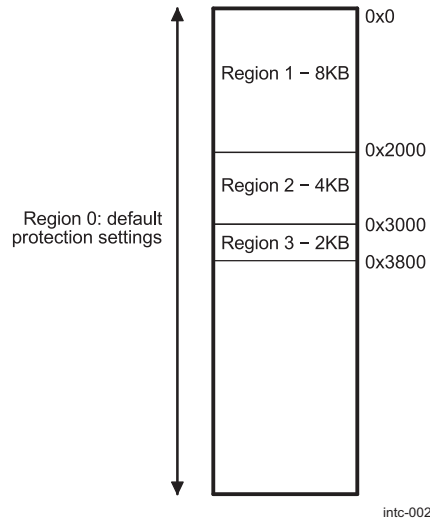

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=3)= 0x3012 (start address 0x3000, level 1, size 2K bytes,

address space 2)

- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=3) = 0x0300
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=3) = 0x0406
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=3) = 0x0002

Figure 9-11 shows the firewall configuration for Solution 1.

Figure 9-11. Firewall Configuration Solution 1

Solution 2

Set Region 0 to accept all accesses:

- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=0) = 0xFFFF
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=0) = 0x140E
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=0) = 0x140E

Set Region 2 to cover 16K bytes:

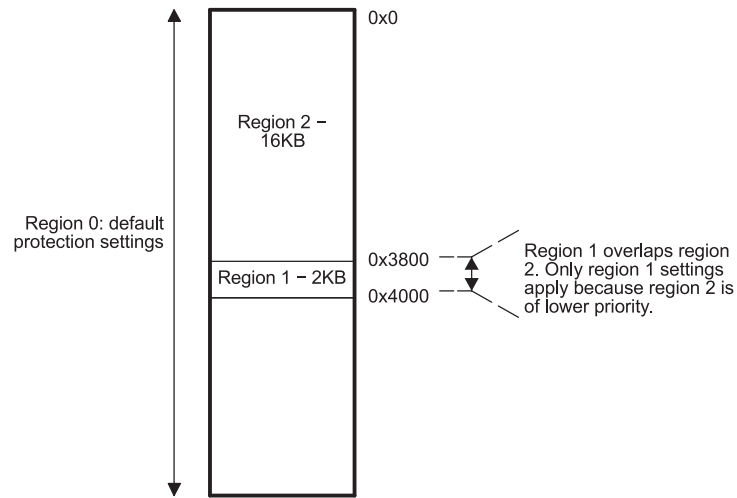

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=2) = 0x2A (start address 0x0, level 1, size 16K bytes, address space 2)
- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=2) = 0x0300
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=2) = 0x0406 (IVA2.2 DMA and MMU and MPU are allowed)
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=2) = 0x0002 (only MPU is allowed to write)

Set Region 1 to mask the last 2K bytes:

- PM_IVA2.2.L3_PM_ADDR_MATCH_k (k=2) = 0x3812 (start address 0x3800, size 2K bytes, address space 2)
- PM_IVA2.2.L3_PM_REQ_INFO_PERMISSION_i (i=1) = 0xFFFF
- PM_IVA2.2.L3_PM_READ_PERMISSION_i (i=1) = 0x042E
- PM_IVA2.2.L3_PM_WRITE_PERMISSION_i (i=1) = 0x042E

9.2.5.1 L3 Initiator Agent (L3 IA)

This section describes the IA register block. Each IA in L3 interconnect has its own IA register block.

The following are the IA registers:

- MPU subsystem port
- IVA2.2 subsystem port
- SGX subsystem port
- High-Speed USB Host
- High-Speed USB OTG
- System DMA read port
- System DMA write port
- Display subsystem port
- Camera subsystem port
- DAP port

- Die-to-die

Table 9-34 through Table 9-37 list the IA registers and their physical addresses, depending on the module instance.

Table 9-34. Initiator Agent Common Register Summary

9.2.5.2 L3 Target Agent (L3 TA)

This section describes the TA register block. Each TA in L3 interconnect has its own register block.

The following are the TA registers:

- SDRAM memory scheduler (TA_SMS module)
- General-purpose memory controller (TA_GPMC module)
- On-chip memory RAM (TA_OCM_RAM module)
- On-chip memory ROM (TA_OCM_ROM module)
- Master D2D (TA_MAD2D module)
- IVA2.2 subsystem (TA_IVA2.2 module)
- SGX subsystem (TA_SGX module)
- L4-Core interconnect (TA_L4_CORE module)
- L4-Per interconnect (TA_L4_PER module)
- L4-Emu interconnect (TA_L4_EMU module)

[Table 9-50](#) through [Table 9-53](#) lists all initiator target registers and their physical addresses depending on the module instance.

[Table 9-54](#) through [Table 9-64](#) describe the individual common registers in the module instance.

Table 9-50. Target Agent Common Register Summary

Register Name	Type	Register Width (Bits)	TA_SMS Physical Address	TA_GPMC Physical Address	TA_OCM_RAM Physical Address

9.2.5.4 Protection Mechanism (PM)

This section describes the protection mechanism register block.

The following are the protection mechanism registers:

- Register target (PM_RT module)
- General-purpose memory controller (PM_GPMC module)
- On-chip RAM (PM_OCM_RAM module)
- On-chip ROM (PM_OCM_ROM module)
- IVA2.2 subsystem (PM_IVA2.2 module)

Table 9-75 and Table 9-77 list the protection registers and their physical addresses, depending on the module instance.

Table 9-78 through Table 9-88 describe the individual common registers in the module instance.

Table 9-75. Protection Mechanism Common Register Summary

9.3 L4 Interconnects

9.3.1 Overview

To connect peripheral modules, the device uses four separate L4 interconnect structures. Although all L4 interconnects handle transfers with peripherals, the interconnects are in different power domains. The L4 interconnect is composed of the following:

- L4-Core: Includes the majority of the peripherals and the configuration interface for L3 interconnect system modules
- L4-Per: Includes peripherals that do not need to be mapped in the CORE power domain
- L4-Wakeup: Includes the peripherals attached to the WKUP power domain
- L4-Emu: Includes emulation peripherals attached to the EMU power domain

The following are the main features of the L4 interconnects:

- Single port to connect to L3 interconnect
 - L4-Core
 - L4-Per
- Dual ports for the following:
 - L4-Emu to connect to the L3 interconnect and DAP
 - L4-Wakeup to connect to the L4-Core and L4-Emu
- Single 32-bit initiator for the L3 port
- Multitarget ports (one per target interface on the L4 interconnect)
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian
- Nonblocking with fair arbitration between threads
- Peripherals are not burst-capable; the system initiators can address bursts to them, but the L4 interconnect breaks the bursts into single accesses.
- Target interfaces: Fully synchronous or divided synchronous
- Peak bandwidth of L4 interconnect is 1 MBps × L4 frequency in MHz per L4 thread (that is, 100 MBps, when the L4 frequency is 100 MHz).
- Latency: Three cycles on request, one cycle on response
- Protection logic provides user-configurable access control to targets by each initiator:
 - Firewall in L4-Core protects the core and wake-up peripherals.
 - Firewall in L4-Per protects per peripherals.
 - Firewall in L4-Emu protects emulation and wake-up peripherals

NOTE: L4-Wakeup has two input ports from L4-Core and L4-Emu. Therefore, wake-up peripherals appear in two locations in the memory mapping. Normally, L4-Emu limits its access except when debugging.

NOTE: L4_CORE has four threads (maximum), L4_PER has four threads (maximum), and L4_EMU and L4_WKUP have one thread.

Figure 9-13 shows an overview of the L4 interconnects and the peripherals attached to them.

Figure 9-13. L4 Interconnect Overview

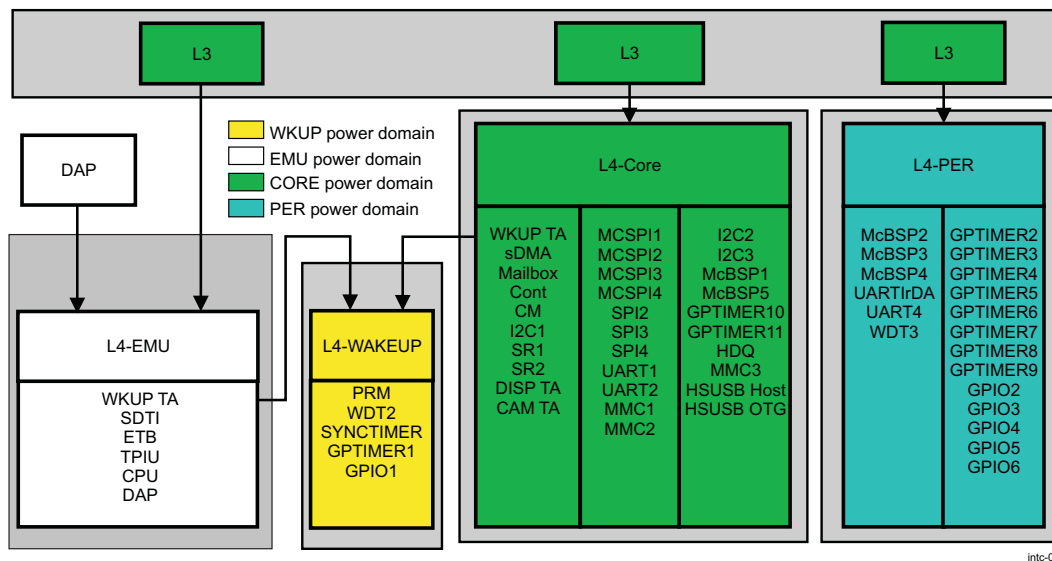

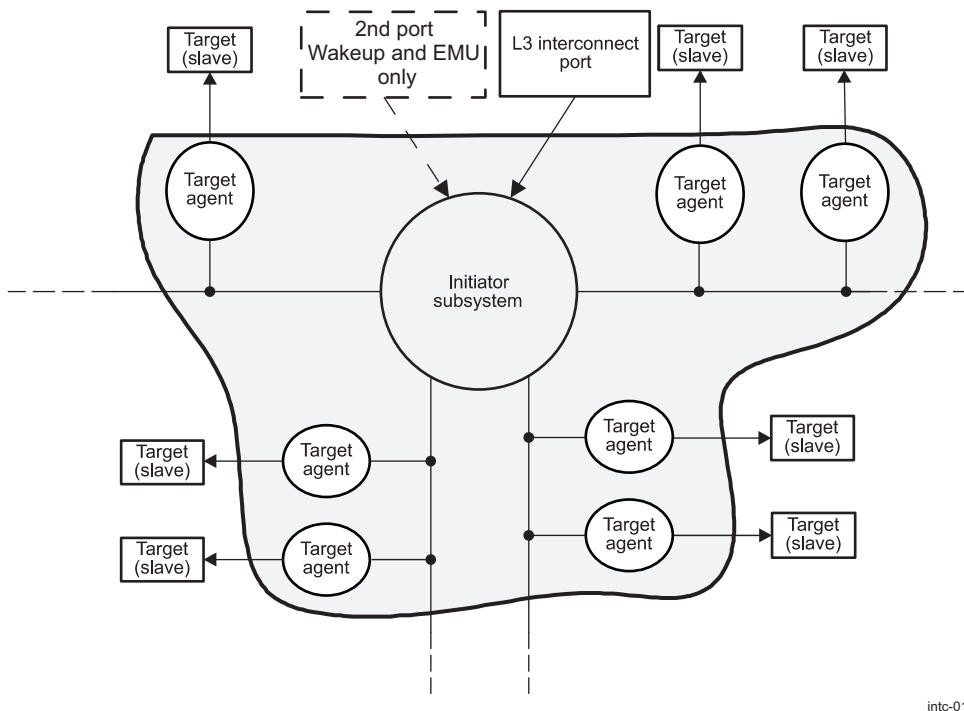

Figure 9-14 shows an internal view of the L4 interconnects in the overall interconnect. This architecture, with only one initiator module (the initiator subsystem) distributing transactions to all target modules (peripherals), enables the firewall functions of the L4 interconnects to be centralized at the L4 initiator level. The L4 firewall filters the accesses according to the configurable protection groups defined in the L4 address protection (AP) registers. Each module or agent is assigned to a protection group. Configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 9-14. L4 Initiator-Target Connectivity for L4-Core and L4-Per

NOTE: As Figure 9-14 shows, targets are attached to branches. These branches have no functional effect and are present for timing closure reasons only.

9.3.1.1 L4-Core Interconnect

The L4-core interconnect handles only transfers to peripherals in the CORE power domain. [Table 9-104](#) lists the TAs.

Table 9-104. L4-Core Target Agents

Module Name	Description
Display subsystem	Display subsystem configuration port
Camera subsystem	Camera subsystem port
USBHS OTG	Universal serial bus High-Speed port OTG
USBHS Host	Universal serial bus High-Speed port Host
USBTLL	USB Transceiver Less Link
UART1	Universal asynchronous receiver transmitter port 1
UART2	Universal asynchronous receiver transmitter port 2
I2C1	Multimaster inter-integrated circuit 1
I2C2	Multimaster inter-integrated circuit 2
I2C3	Multimaster inter-integrated circuit 3
McBSP1	Multichannel buffered serial port 1
McBSP5	Multichannel buffered serial port 5
GPTIMER10	General-purpose timer 10
GPTIMER11	General-purpose timer 11
MMC1	Multimedia memory controller SDIO 1
MMC2	Multimedia memory controller SDIO 2
MMC3	Multimedia memory controller SDIO 3
HDQ/1-Wire	Single wire serial link low rate
MLB (mailbox)	Mailbox
MCSP11	Serial peripheral interface 1
MCSP12	Serial peripheral interface 2
MCSP13	Serial peripheral interface 3
MCSP14	Serial peripheral interface 4
SR1	SmartReflex1
SR2	SmartReflex2
sDMA	System DMA controller
L4-Wakeup	L4-Wakeup interconnect
CM	Clock manager
SCM	System control module

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Core targets.

For the list of initiators authorized to access the L4-Core peripherals, see [Table 9-14](#). For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

9.3.1.2 L4-Per Interconnect

The L4-Per interconnect handles only transfers to peripherals in the PER power domain. [Table 9-105](#) lists the TAs.

Table 9-105. L4-Per Target Agents

Module Name	Description
UARTIrDA	Universal asynchronous receiver/transmitter and infrared data association port

Table 9-105. L4-Per Target Agents (continued)

Module Name	Description
UART4	Universal asynchronous receiver transmitter port 4
McBSP2	Multichannel buffered serial port 2
McBSP3	Multichannel buffered serial port 3
McBSP4	Multichannel buffered serial port 4
GPTIMER2	General-purpose timer 2
GPTIMER3	General-purpose timer 3
GPTIMER4	General-purpose timer 4
GPTIMER5	General-purpose timer 5
GPTIMER6	General-purpose timer 6
GPTIMER7	General-purpose timer 7
GPTIMER8	General-purpose timer 8
GPTIMER9	General-purpose timer 9
GPIO2	General-purpose I/O 2
GPIO3	General-purpose I/O 3
GPIO4	General-purpose I/O 4
GPIO5	General-purpose I/O 5
GPIO6	General-purpose I/O 6

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Per targets.

For the list of initiators authorized to access the L4-Per peripherals, see [Table 9-14](#). For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

9.3.1.3 L4-Emu Interconnect

The L4-Emu interconnect handles only transfers to peripherals in the EMU power domain. [Table 9-106](#) lists the TAs.

Table 9-106. L4-Emu Target Agents

Module Name	Description
L4-Wakeup	L4-Wakeup interconnect
SDTI	System debug trace interface
ETB	Embedded trace buffer
TPIU	Trace port interface unit
MPU	ARM9
DAP	Debug access port

Not all initiators can access all the targets in the L4-Emu interconnect. Additional restrictions affect the ability of these initiators to access the L4-Emu peripherals. [Table 9-107](#) lists which initiators can access the L4-Emu interconnect.

NOTE: For the list of initiators authorized to access the L4-Emu peripherals, see [Table 9-14](#). For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

Table 9-107. L4-Emu Initiator Agents

Module Name	Description
L3 interconnect	L3 interconnect port
DAP	DAP port

9.3.1.4 L4-Wakeup Interconnect

The L4-Wakeup interconnect handles only transfers to peripherals in the WKUP power domain. [Table 9-108](#) lists the TAs.

Table 9-108. L4-Wakeup Target Agents

Module Name	Description
PRM	Power reset manager
GPIO1	General-purpose I/O 1
GPTIMER1	General-purpose timer 1
WDTIMER2	MPU subsystem watchdog timer
32KTIMER	32-kHz timer

Initiators that can access the L4-Core or L4-Emu can access all the targets in the L4-Wakeup interconnect. [Table 9-109](#) lists the initiators that can access the L4-Wakeup interconnect. For details on restricted access, see [Section 9.3.3.3.1, Protection Mechanism](#).

Table 9-109. L4-Wakeup Initiator Agents

Module Name	Description
L4-Core interconnect	L4-Core interconnect port
L4-Emu interconnect	L4-Emu interconnect port

9.3.2 L4 Interconnects Integration

9.3.2.1 Clocking, Reset, and Power-Management Scheme

9.3.2.1.1 Clocks

Four functional clocks are used in each L4 interconnect (see [Table 9-110](#)).

Table 9-110. L4 Interconnect Clocks

Clock	Frequency	Name	Comments
L4-Core interconnect clock	Up to Core_L3_ICLK/2	CORE_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Per interconnect clock	Up to Core_L3_ICLK/2	PER_L4_GICLK	Source, control, and gating handled by PRCM module
L4-Emu clock		L4_EMU	Clock for emulation
L4-Wakeup interconnect clock		WKUP_L4_GICLK	Source, control, and gating handled by PRCM module

9.3.2.1.2 Resets

9.3.2.1.2.1 Hardware Reset

L4 interconnects receive a reset signal from the PRCM module, which is the reset signal to the CORE power domain. For more details, see *Power, Reset, and Clock Management*.

[Table 9-111](#) lists the hardware reset for the L4-Core interconnect.

Table 9-111. L4 Interconnect Hardware Reset

Interconnect	Reset Domain
L4-Core interconnect	CORE_RST
L4-Per interconnect	PER_RST
L4-Wakeup interconnect	WKUP_RST
L4-Emu interconnect	EMU_RST

9.3.2.1.2.2 Software Reset

The L4 interconnects have hardware reset capabilities, but do not have software reset capabilities. The hardware reset capabilities are controlled by the PRCM module and are applied to the L4 interconnects and the connected L4 TAs and L4 target modules.

9.3.2.1.3 Power Domain

For more details on power voltage scaling, see *Power, Reset, and Clock Management*.

[Table 9-112](#) lists the power domains for the L4-Core and L4-Wakeup interconnects.

Table 9-112. L4 Interconnect Power Domains

Interconnect	Power Domain
L4-Core interconnect	CORE
L4-Per interconnect	PER
L4-Emu interconnect	EMU
L4-Wakeup interconnect	WKUP

9.3.2.1.4 Power Management

9.3.2.1.4.1 Module Power-Saving

The L4 interconnect automatically performs internal clock autogating to reduce power consumption. Though not recommended, it is possible to deactivate clock autogating by writing 1 to the `CLOCK_GATE_DISABLE` bit `L4_LA_NETWORK_CONTROL_H[24]` of each L4 interconnect. Clock autogating is enabled by default.

9.3.2.1.4.2 System Power Management and Wakeup

As part of the system-wide power-management scheme, the L4 interconnect enters an idle state at the request of the PRCM module (for more information, see *Power, Reset, and Clock Management*). The L4 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all the transfer requests are complete. This functionality is handled by hardware. The L4 interconnect sends an acknowledge signal back to the PRCM module when it enters idle state.

9.3.3 L4 Interconnects Functional Description

9.3.3.1 L4-Interconnects Initiator Identification

In the device interconnect, a ConnID is an initiator module identifier. The L4 interconnect uses the same ConnID as L3.

9.3.3.2 Endianness Management

Both L4 interconnects are little-endian only. Any initiator accessing the L4 interconnect module must consider byte ordering and perform a conversion, if necessary.

9.3.3.3 L4 Protection and Firewalls

9.3.3.3.1 Protection Mechanism

The following two parameters are used to set up access permission because of the large address spaces and the number of peripherals connected to the L4 interconnects:

- Programmable groups for initiators:
 - 8 protection groups for the L4-Core interconnect
 - 8 protection groups for the L4-Per interconnect
 - 6 protection groups for the L4-Emu interconnect
- Each segment is divided into regions of 2K bytes:
 - 100 regions for the L4-Core interconnect
 - 43 regions for the L4-Per interconnect
 - 26 regions for the L4-Emu interconnect

NOTE: Regions and segments are present for the L4-Wakeup interconnect but cannot be programmed. The L4-Wakeup protection is done through the L4-Core and L4-Emu interconnects.

A protection group is a group of targets that have the same protection settings. Initiator access is defined by `CONNID_BIT_VECTOR` field `L4_AP_PROT_GROUP_k_L[15:0]`. The initiators have the same access permission to all regions in this group.

A region is programmed to allow access to a unique selectable protection group by using `PROT_GROUP_ID` field `L4_AP_REGION_I_H[22:20]`.

NOTE: k denotes the protection group number.

l denotes the region number.

9.3.3.3.2 Protection Group

A protection group defines which initiators with a given MReqInfo can access the targets agent protected by this group.

The CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k[15:0] (see [Figure 9-15](#)) is a 1-bit vector that sets up initiator permission access regions. A protection group is accessible by an initiator if the bit position corresponding to its ConnID is set to one in the CONNID_BIT_VECTOR field.

The ENABLE field L4_AP_PROT_GROUP_ROLES_k[31:0] lists all possible MReqInfo combinations. Setting a Req bit in this register determines the type of access allowed to the initiator. See [Section 9.2.3.3.4, REQ_INFO_PERMISSION Configuration](#), for more information. MReqInfo is used in L4 the same way it is used in the L3 firewall configuration.

NOTE: Permissions are identical for read and write accesses in L4 interconnect targets.

[Figure 9-15](#) shows an example of CONNID_BIT_VECTOR.

Figure 9-15. Example of CONNID_BIT_VECTOR

Setting bits 1 and 4 in the PROT_GROUP_ID_1 defines a group initiator able to access targets in protection group 1, and includes:

- MPU SS
- IVA2.2 MMU

Protection group 1 (PG1) can be applied to multiple protection regions without limitation. Each protection region l that is configured with PG1 enables permission access to these two initiators only.

The firewall default configuration for the L4-Core interconnect contains eight protection groups:

- Most regions are, by default, set with protection group 7 (PG7), which is configured for all access (see [Table 9-113](#)).
- Protection group 0 (PG0) is restricted to the MPU subsystem.

- The DSS is attached to protection group 2 (PG2).
- The Camera is attached to protection group 3 (PG3).
- By default, PG5 to PG7 are configured for all access.

The L4-Per interconnect contains eight protection groups:

- By default, PG0 to PG7 are configured for all access.
- By default, most regions are set with PG7, which is configured for all access (see [Table 9-114](#)).

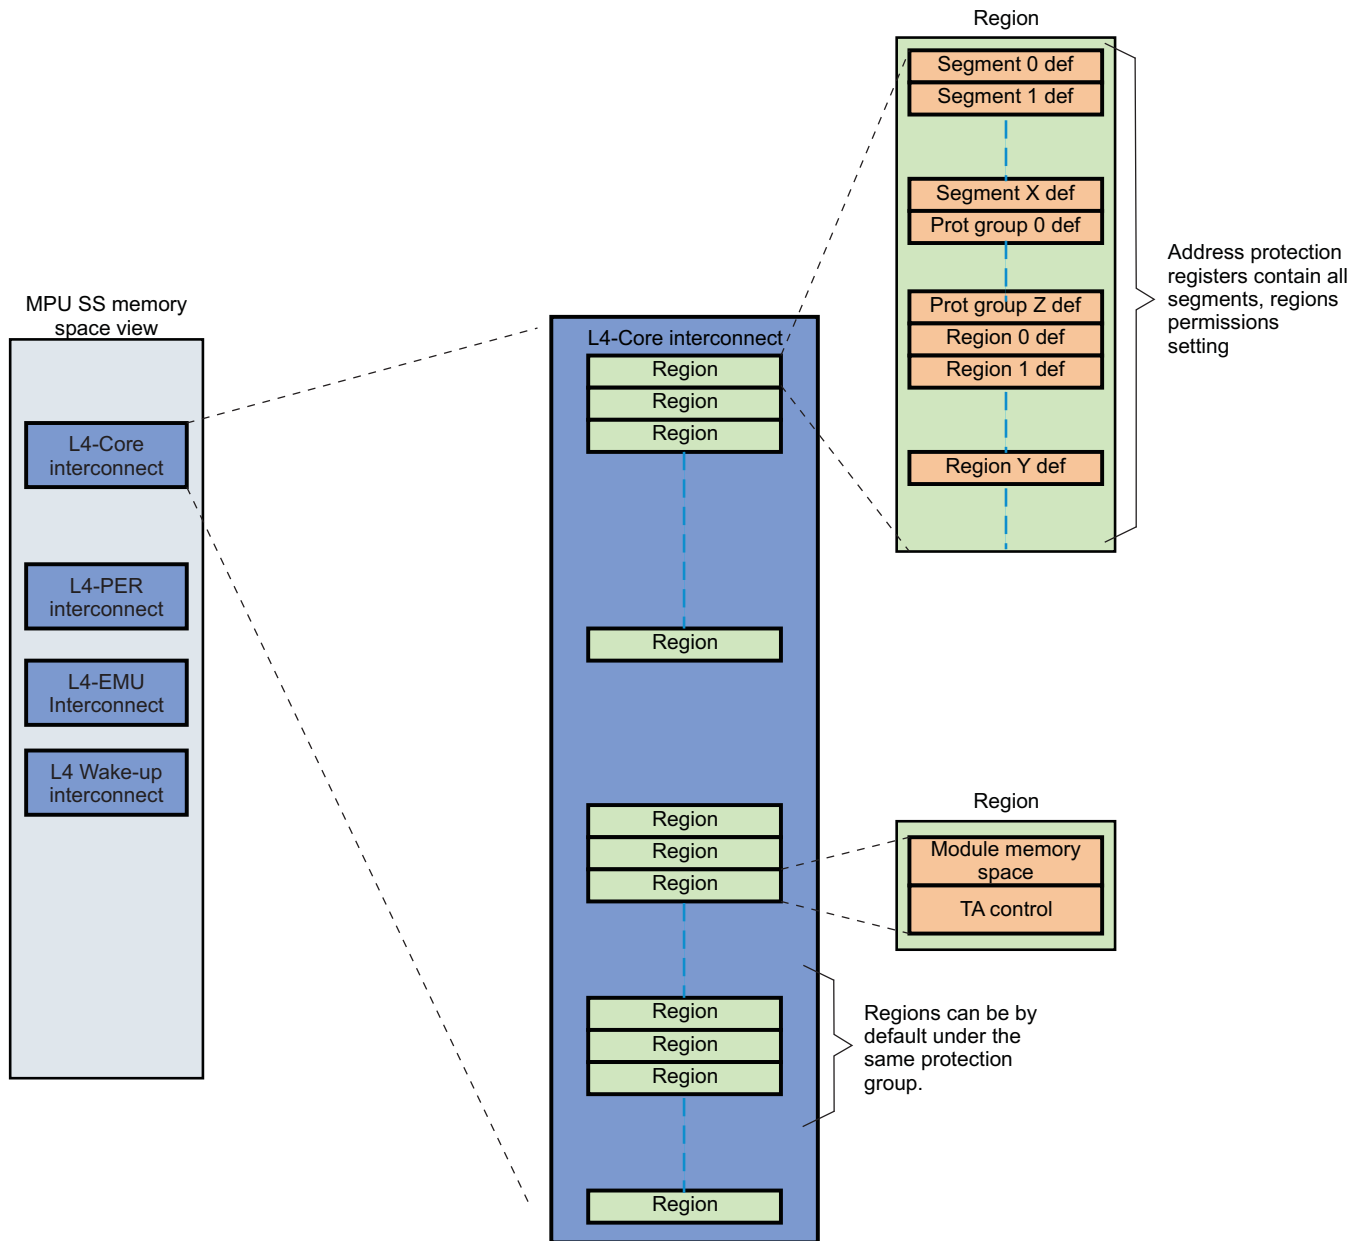

The L4-Emu interconnect contains six protection groups:

- By default, most regions are set with PG5, which is configured for all access (see [Table 9-115](#)).
- The AP is attached to PG0.
- The emulation organs are attached to PG3.

9.3.3.3.3 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation (see [Figure 9-16](#)). By default, some regions are attached to a specific protection group. This specificity allows the user to set up the permission access for certain types of modules that require the same access protection without managing the region allocation.

Figure 9-16. L4 Firewall Overview

intc-018

All interconnect address spaces are covered by regions. [Table 9-113](#) to [Table 9-115](#) list the module mapping, including the address, region number, and default protection group allocated to it.

By setting ENABLE bit L4_AP_REGION_y_H[0] to 0, the region becomes inactive and therefore inaccessible. Setting the bit to 1 activates the region.

Table 9-113. Region Allocation for L4-Core Interconnect

9.3.3.3.4 L4 Firewall Address and Protection Registers Setting

Table 9-116 lists the settings of the AP registers for an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 9-116. L4 Firewall Register Description Overview

Register Type	Register Name	Bits	Field	Description
Segment	L4_AP_SEGMENT_i_L	23:0	Base	Segment base address
	L4_AP_SEGMENT_i_H	4:0	SIZE	Segment size equals to 2 power of SIZE
Protection groups	L4_AP_PROT_GROUP_MEMBERS_k_L	15:0	CONNID_BIT_VECTOR	See Section 9.3.3.1 for L4ConnID).
	L4_AP_PROT_GROUP_ROLES_k_L	15:0	ENABLE	Refer to Table 9-22 for MReq description

Table 9-116. L4 Firewall Register Description Overview (continued)

Register Type	Register Name	Bits	Field	Description
Region setting	L4_AP_REGION_L_L	23:0	BASE	Define the base address of region in respect to its respective segment base address
	L4_AP_REGION_L_H	27:24	SEGMENT_ID	Segment ID number of the region
		22:20	PROT_GROUP_ID	The protection group attached to the region
		19:17	BYTE_DATA_WIDTH_EXP	Determine the number of bytes in an access
		5:1	SIZE	Size of the region equals to 2 power of SIZE
		0	ENABLE	Enable the region protection

9.3.3.4 Error Handling

9.3.3.4.1 Overview

The L4 interconnect provides mechanisms for handling either internally detected errors or errors reported by modules attached to the L4 target ports. Hardware support facilitates logging errors and cleaning up the state to allow error recovery software to treat the error.

As an L3 target, the L4 interconnect reports errors to the L3 interconnect in-band whenever possible. In-band error reporting is the default and recommended configuration. It is assumed that INBAND_ERROR_REP bit [L4_IA_AGENT_CONTROL_L\[27\]](#) is set to 1.

NOTE: *L4_IA* denotes which interconnect is considered: L4-Core, L4-Per, L4-Emu, or L4-Wakeup.
L4_TA denotes the module name, such as UART1, McBSP1, etc.

The L4 interconnects handle three types of errors:

- No target core found or address hole
- Request protection violation
- Failure of the target to service a request before a time-out expires

9.3.3.4.2 Error Logging

9.3.3.4.2.1 No Target Core Found/Address Hole

This error indicates that a request was addressed to a hole in the L4 address map.

When this occurs, an in-band error response is returned to the L3 level.

The error is also logged into the INBAND_ERROR bit [L4_IA_AGENT_STATUS_L\[27\]](#).

Additionally, an address hole error code is logged into the CODE field [L4_IA_ERROR_LOG_L\[25:24\]](#).

The [L4_IA_ERROR_LOG](#) register also includes MULTI bit [L4_IA_ERROR_LOG_L\[31\]](#), which is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

9.3.3.4.2.2 Protection Violation

This error indicates that an initiator has accessed a restricted region. This error is reported using an in-band error. It is written to the INBAND_ERROR field. A protection violation error code is also saved in the CODE field [L4_IA_ERROR_LOG_L\[25:24\]](#).

The protection violation is also logged in the CONTROL.CONTROL_PROT_ERR_STATUS [7] register of the system control module.

NOTE: There is no specific error signal for the protection violation that goes out from the L4 interconnects. The out-band error that goes to the system control module indicates a protection violation, but it also indicates normal interconnect errors.

9.3.3.4.2.3 Time-Out

This section gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled on a per-target basis in the [L4_TA_AGENT_CONTROL_L](#) register. If the mechanism is enabled for a TA, and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit [L4_TA_AGENT_STATUS_L\[8\]](#). The affected TA enters an error state that causes it to send error responses to any new request targeted at it. To recover from this state, the TA must be reset by system software. The time-out is counted starting from the moment a command is presented to the target, regardless of how the target responds to the command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. These four signals are referred to as 1X-time base, 4X-time base, 16X-time base, and 64X-time base.

The time-base circuit offers four possible sets of time-base signals. Selection is done by programming TIMEOUT_BASE field [L4_LA_NETWORK_CONTROL_L\[10:8\]](#). [Table 9-117](#) lists the values in the number of L4 clock cycles.

Table 9-117. L4 Time-Out Link and TA Programming

TIMEOUT_BASE[2:0]	REQ_TIMEOUT[2:0]				
	0	1	2	3	4
0	All L4 time-out features are disabled.				
1	Locally disabled	64	256	1024	4096
2		256	1024	4096	16384
3		1024	4096	16384	65536
4		4096	16384	65536	262144

The reset value is 0x4, resulting in the longest possible time-out.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, by using REQ_TIMEOUT field [L4_TA_AGENT_CONTROL_L\[10:8\]](#) (see [Table 9-118](#)).

Table 9-118. L4 Time-Out TA Programming

REQ_TIMEOUT	Target Agent Time-Out Reference
0	Time-out locally disabled
1	1X-base cycle
2	4X-base cycle
3	16X-base cycle
4	64X-base cycle

A time-out condition is detected when the command acceptance or the response is not received after a delay of between one and three time-base periods.

Example:

- L4 frequency = 100 MHz
- TIMEOUT_BASE = 4 in the [L4_LA_NETWORK_CONTROL_L](#) register

- REQ_TIMEOUT = 2 in the [L4_TA_AGENT_CONTROL_L](#) for target agent A
- REQ_TIMEOUT = 4 in the [L4_TA_AGENT_CONTROL_L](#) for target agent B

At agent A, the time-base unit is 16384 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 164 μ s to 492 μ s.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 2.6 ms to 7.8 ms.

On detection of a time-out condition, the agent automatically generates an error response to the inter_IA, which is forwarded to the L3. The agent also logs the time-out to REQ_TIMEOUT bit [L4_TA_AGENT_STATUS_L\[8\]](#).

After the time-out has been detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module by using its internal soft reset bit, and then the TA by using OCP_RESET bit [L4_TA_AGENT_CONTROL_L\[0\]](#).

9.3.3.4.3 TA Software Reset

Writing 1 to OCP_RESET bit [L4_TA_AGENT_CONTROL_L\[0\]](#) initiates the software reset period. The software reset must be asserted for at least 16 cycles of the target module OCP clock, which can be a divided clock with respect to the L4 clock.

During the software reset period the following occur:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to avoid getting unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The [L4_TA_AGENT_STATUS_L\[8\]](#) REQ_TIMEOUT status bit is cleared.

Writing 0 to the [L4_TA_AGENT_CONTROL_L\[0\]](#) OCP_RESET bit terminates the software reset period.

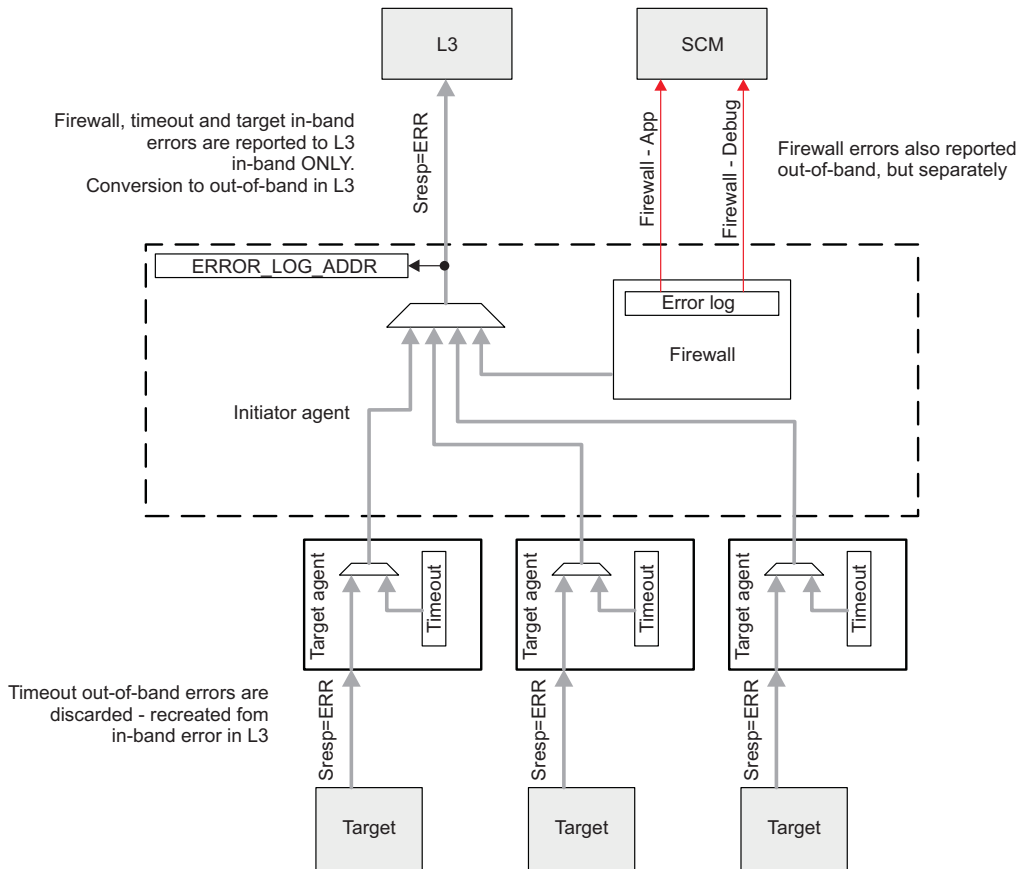

The attached module must then be reset to complete the recovery.

9.3.3.4.4 Error Reporting

[Figure 9-17](#) illustrates the error-reporting scheme used in the L4_Core, L4_Per, and L4_EMU interconnects.

- Timeout error generation is enabled at each TA.
- Timeout error and target in-band errors are only reported in-band to the L3 initiator.
- Protection violations are reported out-of-band. Error steering is used to distinguish between application or debug errors.

Figure 9-17. L4 Error Reporting

9.3.4 L4 Interconnect Programming Guide

9.3.4.1 L4 Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

9.3.4.1.1 Global Initialization

9.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the L4 interconnect module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see , L4 Interconnect Integration.

Table 9-119. Global Initialization of Surrounding Modules

Surrounding Modules	Comments
PRCM	For more information about the configuration of the module, see Chapter 3, Power, Reset, and Clock Management .
Control module	For more information about the configuration of the module, see , Control Module .
MPU INTC	The MPU INTC must be configured to enable the interrupts from the L4 interconnect module. See Chapter 12, Interrupt Controllers .
sDMA	For more information about the configuration of the sDMA, see , sDMA .

Table 9-119. Global Initialization of Surrounding Modules (continued)

Surrounding Modules	Comments
L3 interconnect	For more information about the interconnect configuration, see , <i>Interconnect</i> .

9.3.4.1.2 Operational Modes Configuration

9.3.4.1.2.1 L4 Interconnect Error Analysis Mode

9.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

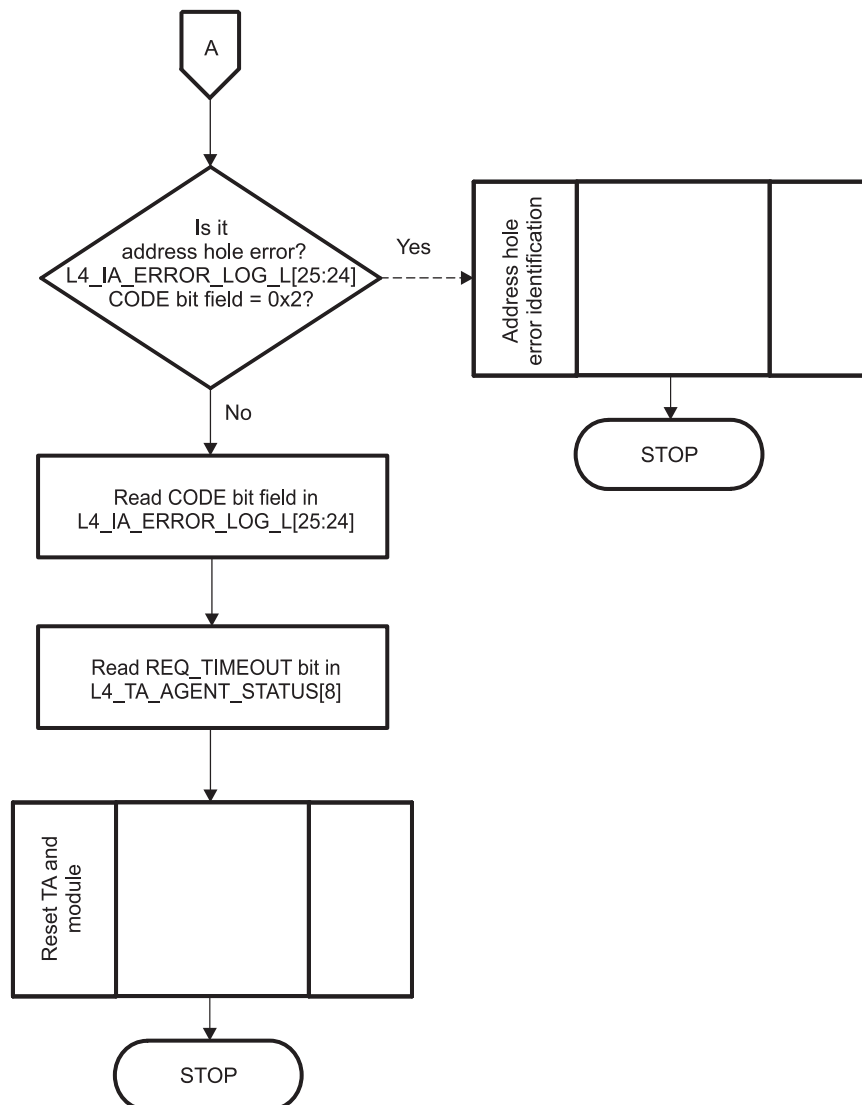

[Figure 9-18](#) and [Figure 9-19](#) show the software sequence required in most cases.

[Table 9-120](#) and [Table 9-121](#) show the main sequence for error analysis mode and its subprocess call summary, respectively.

Figure 9-18. Typical Error Analysis Sequence

Table 9-121. Subprocess Call Summary for Main Sequence – Error Analysis Mode

Subprocess	Cross-Reference
L3 interconnect error analysis	Section 9.2.3.4, Error Handling
L4 interconnect protection violation error identification	Section 9.3.4.1.2.1.2, Subsequence: L4 Interconnect Protection Violation Error Identification
L4 interconnect unsupported command/address hole error identification	Section 9.3.4.1.2.1.3, Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification
L4 interconnect reset TA and module	Section 9.3.4.1.2.1.4, Subsequence: L4 Interconnect Reset TA and Module

9.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see [Table 9-122](#)).

Table 9-122. Protection Violation Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read error code.	L4_IA_ERROR_LOG_L[25:24] CODE	
IF: Is it an inband error?	L4_IA_AGENT_STATUS_L[27] INBAND_ERROR_REP	=0x1
Read status bits.	CONTROL.CONTROL_SEC_ERR_STATUS[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_SEC_ERR_STATUS[17:16]	0x3
Write 1 to clear IA status bit.	L4_IA_AGENT_STATUS_L[27] INBAND_ERROR_REP	0x1
ELSE		
Read status bits.	CONTROL.CONTROL_PROT_ERR_STATUS_DE BUG[17:16]	
Write 1 to clear status bits.	CONTROL.CONTROL_PROT_ERR_STATUS_DE BUG[17:16]	0x3
ENDIF		
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear MError status.	L4_IA_AGENT_STATUS_L[24] MERROR_REP	0x1

9.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see [Table 9-123](#)).

Table 9-123. Unsupported Command/Address Hole Error Identification

Step	Register/Bit Field/Programming Model	Value
Read multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	
Read initiator error code.	L4_IA_ERROR_LOG_L[25:24] CODE	
Write 1 to clear multiple errors detection.	L4_IA_ERROR_LOG_L[31] MULTI	0x1
Write 1 to clear inband error status.	L4_IA_AGENT_STATUS_L[27] INBAND_ERROR_REP	0x1

9.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure resets the TA and module (see [Table 9-124](#)).

Table 9-124. Reset TA and Module

Step	Register/Bit Field/Programming Model	Value
Reset TA.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x1
Wait until target module clock = 16 cycles.		
Write 0 to clear TA time-out status.	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	0x0
Write 0 to clear TA reset.	L4_TA_AGENT_CONTROL_L[0] OCP_RESET	0x0
Reset the attached module. ⁽¹⁾		

⁽¹⁾ For more information, see the respective module chapter.

9.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

9.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see [Table 9-125](#)).

Table 9-125. Time-Out Configuration

Step	Register/Bit Field/Programming Model	Value
Disable time-out.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	0x0
Clear TA time-out error status. ⁽¹⁾	L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT	0x1
Set time-out at TA level. ⁽¹⁾	L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT	xxx
Set time-out base.	L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE	xxx

⁽¹⁾ Must be done for each TA

9.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

9.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see [Table 9-126](#)).

Table 9-126. Firewall Configuration

Step	Register/Bit Field/Programming Model	Value
Define the members of protection group k. ⁽¹⁾	L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR	xxx
Define the access type of a protection group k. ⁽¹⁾	L4_AP_PROT_GROUP_ROLES_k_L[15:0] ENABLE	xx
Set region affiliation to protection group. ⁽²⁾	L4_AP_REGION_I_L[22:20] PROT_GROUP_ID	xxx

⁽¹⁾ Must be done for each protection group

⁽²⁾ Must be done for each region

9.3.5 L4 Interconnects Register Manual

A summary of the hardware interface for the L4-Core, L4-Per, L4-Emu, and L4-Wkup interconnects is given in [Table 9-127](#) through [Table 9-130](#), respectively. Each module instance in the design is shown with the module register map and bit definitions for each bit field.

9.3.5.1 L4 Initiator Agent (L4 IA)

This section provides information on the L4 IA module. Each of the registers within the module instance is described separately in [Table 9-131](#) to [Table 9-132](#).

The initiator OCP interface register block (IA) consists of the status, control, and error log registers that can be used to configure the interface of an initiator OCP. There can be only one register block for each initiator OCP interface.

Table 9-131. L4 IA Register Summary (1)

Register Name	Type	Register Width (Bits)	CORE_IA Physical Address	PER_IA Physical Address	EMU_IA_L3 Physical Address

9.3.5.2 L4 Target Agent (L4 TA)

This section provides information on the L4 Target agent (TA) register module. Each of the registers within the module instance is described separately in [Table 9-153](#) to [Table 9-177](#).

[Table 9-153](#) to [Table 9-178](#) provide information on the L4 Target Agent having two supplementary registers OCP_CONTROL and OCP_STATUS

The TA register block consists of the status and control registers that can be used to configure the interfaces of the targets.

Table 9-212. L4_LA_NETWORK_CONTROL_H

Address Offset	0x024
Physical Address	Please refer to Table 9-195
Description	Control interconnect global power control
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved							CLOCK_GATE_DISABLE	Reserved			THREAD0_PRI	Reserved							EXT_CLOCK	Reserved											

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Read returns 0.	R	0x00
24	CLOCK_GATE_DISABLE	When set to 1 this field disables all clock gating.	RW	0
23:21	Reserved	Read returns 0.	R	0x0
20	THREAD0_PRI	Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads.	R	1
19:9	Reserved	Read returns 0.	R	0x000
8	EXT_CLOCK	When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off.	R	1
7:0	Reserved	Read returns 0.	R	0x00

9.3.5.4.1 L4 Address Protection (AP) Registers Description

Table 9-216. L4_AP_COMPONENT_L

Address Offset	0x000
Physical Address	Please refer to Table 9-214
Description	Contains a component code and revision, which are used to identify the hardware of the component.
Type	R
