- Send out two control signals to indicate to the SIDETONE module that the data is valid (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available)
- Receive two 24-bit filtered data channels from the external SIDETONE module and send these channels to the configured transmit channels after mixing the data with the incoming data (from the L4 interface). The sum between the incoming data and SIDETONE loopback data is a saturated sum.
- Receive two control signals to indicate that the SIDETONE module filtered data is available (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available).

Figure 21-53 shows the SIDETONE external module data path:

Figure 21-53. SIDETONE Data Path

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel and SIDETONE mode:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set McBSPi.MCBSPLP_MCR1_REG[0] RMCM=1 to select multichannel mode enable.
- Set a frame length (in McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 bit field and in McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (in McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and in McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see note).
- Select the input/output channels configured as SIDETONE channels and enable SIDETONE by setting the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN, McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN fields (2 out of 4 channels external SIDETONE assignment) and McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit to 1.

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

Figure 21-54 describes the data exchange protocol between McBSP module and SIDETONE core:

Figure 21-54. McBSP to SIDETONE Data Exchange

Figure 21-55 describes the data exchange protocol between SIDETONE core and McBSP module:

Figure 21-55. SIDETONE to McBSP Data Exchange

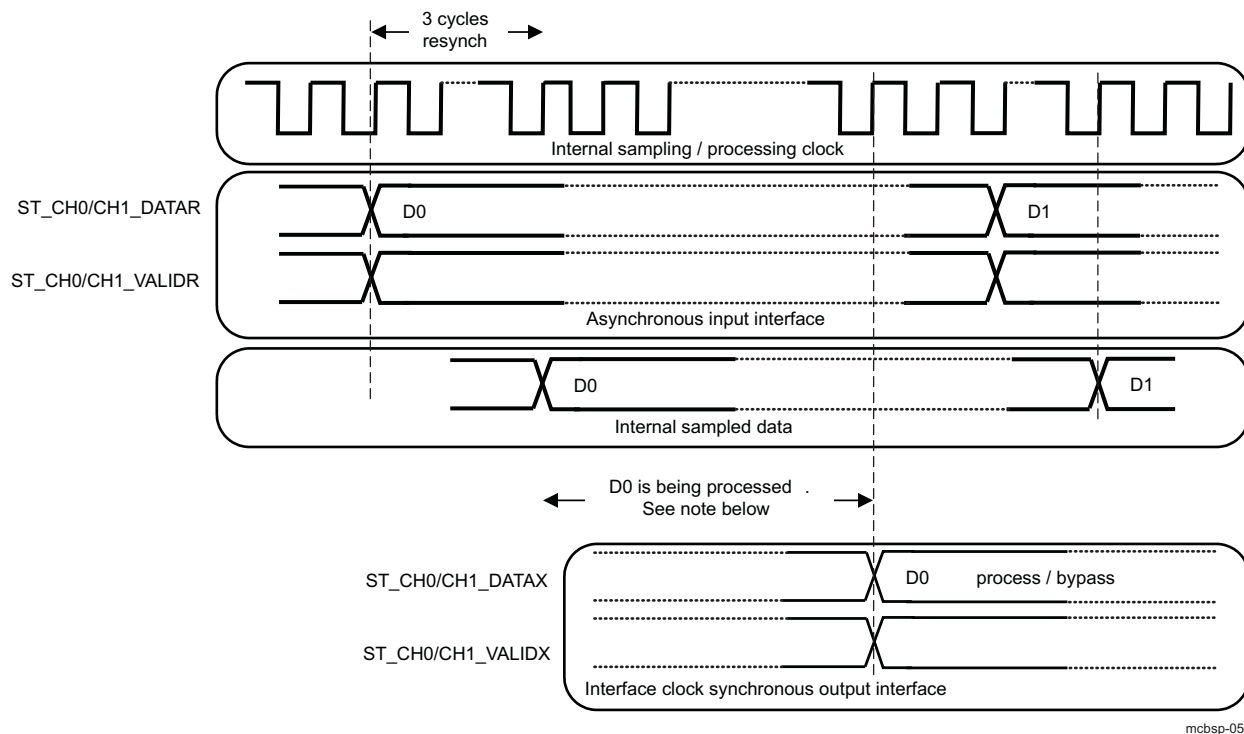

NOTE: To use the same input channel as source for both SIDETONE output channels the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN should be equal to McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN. The McBSP module does not support two input channels to be assigned to only one SIDETONE output channel.

21.4.7.3 Data Processing Path

The SIDETONE core receives the data to be processed through two 24-bits parallel data interfaces, one for each audio channel. When enabled through McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit-field, the module applies the filtering and gain functions to each data item (frame) and outputs it through two similar 24-bits parallel data interfaces.

Figure 21-56 below describes how the data is sampled and output through the dedicated data interfaces.

Figure 21-56. SIDETONE Processed Data Interfaces

NOTE: The processing time needed is 132 clock cycles (SIDETONE enabled). The total number of cycles needed for outputting the new processed data upon arrival of a sample is maximum 135 (including synchronizations). When not enabled, the data response takes maximum 5 clock cycles.

The `ST_CH0_VALIDR` and `ST_CH1_VALIDR` are 1 bit inputs and their toggling information is used to signal that new data is valid for sampling from `ST_CH0_DATAR` / `ST_CH1_DATAR`.

The `ST_CH0_VALIDX` and `ST_CH1_VALIDX` are 1 bit outputs and their toggling information is used to signal that new data is valid on the output data bus `ST_CH0_DATAX` / `ST_CH1_DATAX`.

21.4.7.4 Data Processing

The processing consists in 2 stages filtering and applying gain to signal. The whole process takes 132 clock cycles.

If a new frame comes too early causing the interrupt assertion, the current frame will be completely processed and this new frame will be ignored. Consequent frames will also be ignored until the current frame processing has ended.

21.4.7.4.1 Filtering

A 128 length FIR filter scheme is used. The module must process the two channels in parallel so two instances of filter will work in parallel sharing only the same coefficients.

Samples data are signed values in interval (-1..1) in Q23 format, negative values are expressed in 2's complement. Coefficients are also signed values in interval (-1..1) in Q15 format, negative values are expressed in 2's complement too.

The module handles overflows in the sums of the product but the user should choose the coefficients with the sum of magnitudes in absolute value is smaller than 1, otherwise the user must ensure that gain applying brings the samples value below |1|, to avoid saturation.

$$|C0| + |C1| + \dots + |C127| < 1$$

CAUTION

The coefficients cannot be loaded while the filtering is active (SIDETONE enabled).

21.4.7.4.2 Applying Gain

Each output sample will be multiplied with the gain value specified in the McBSPi.ST_SGAINCR_REG. The gain is independent for each channel and can be modified anytime through L4-interface with immediate effect. Gain values are in the interval (-2..2) in Q1.14 format, negative values are expressed in 2's complement.

The user must choose the gain's value according to the magnitude of the samples to avoid overflow in the final product between the FIR data and gain value. If an overflow occurs, the output data is saturated.

21.4.7.4.3 Enabling SIDETONE

When the SIDETONE operation is enabled (McBSPi.ST_SSELCR_REG[0] SIDETONEEN is 1), the module starts collecting samples received through the data interface without returning any sample or toggling any of the ST_CH0/CH1_VALIDX outputs. The first 127 samples for each channel are only accumulated, no processed data is provided. The first processed frame comes after receiving the 128th sample (with the specific delay).

When the SIDETONE operation is disabled, data is output through the data interface as it comes on the data input interface with the resynchronization latency of maximum 5 clock cycles. Re-enabling it requires waiting another 128 samples before providing new processed samples (each transition of McBSPi.ST_SSELCR_REG[0] SIDETONEEN from 0 to 1 triggers this initialization process).

NOTE: After reset, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit is 0.

21.4.7.4.4 FIR Accuracy

All the arithmetic inside the module is performed without any truncation/saturation until the last stage – the gain applying, where the result of the product between gain and FIR value is saturated to +/-1 if overflow occurs and the LSBs are truncated.

21.4.7.5 Interrupt Operation

The SIDETONE core has a single interrupt line and a single event that may trigger the interrupt. The event (an error one) occurs when the input interface data rate overflows the processing ability of the module. As described in the data processing path section, the SIDETONE core completes a frame processing in 132 cycles. If the input frame rate for any channel exceeds 1 frame/132 x interface clock period while SIDETONE is enabled, the McBSPi.ST_IRQSTATUS_REG[0] OVRERROR bit is set and, if McBSPi.ST_IRQENABLE_REG[0] OVRERRROREN bit is set to 1, the interrupt line is asserted.

21.5 McBSP Basic Programming Model

This section describes the programming model of typical McBSP module and SIDETONE core applications.

21.5.1 McBSP Core

CAUTION

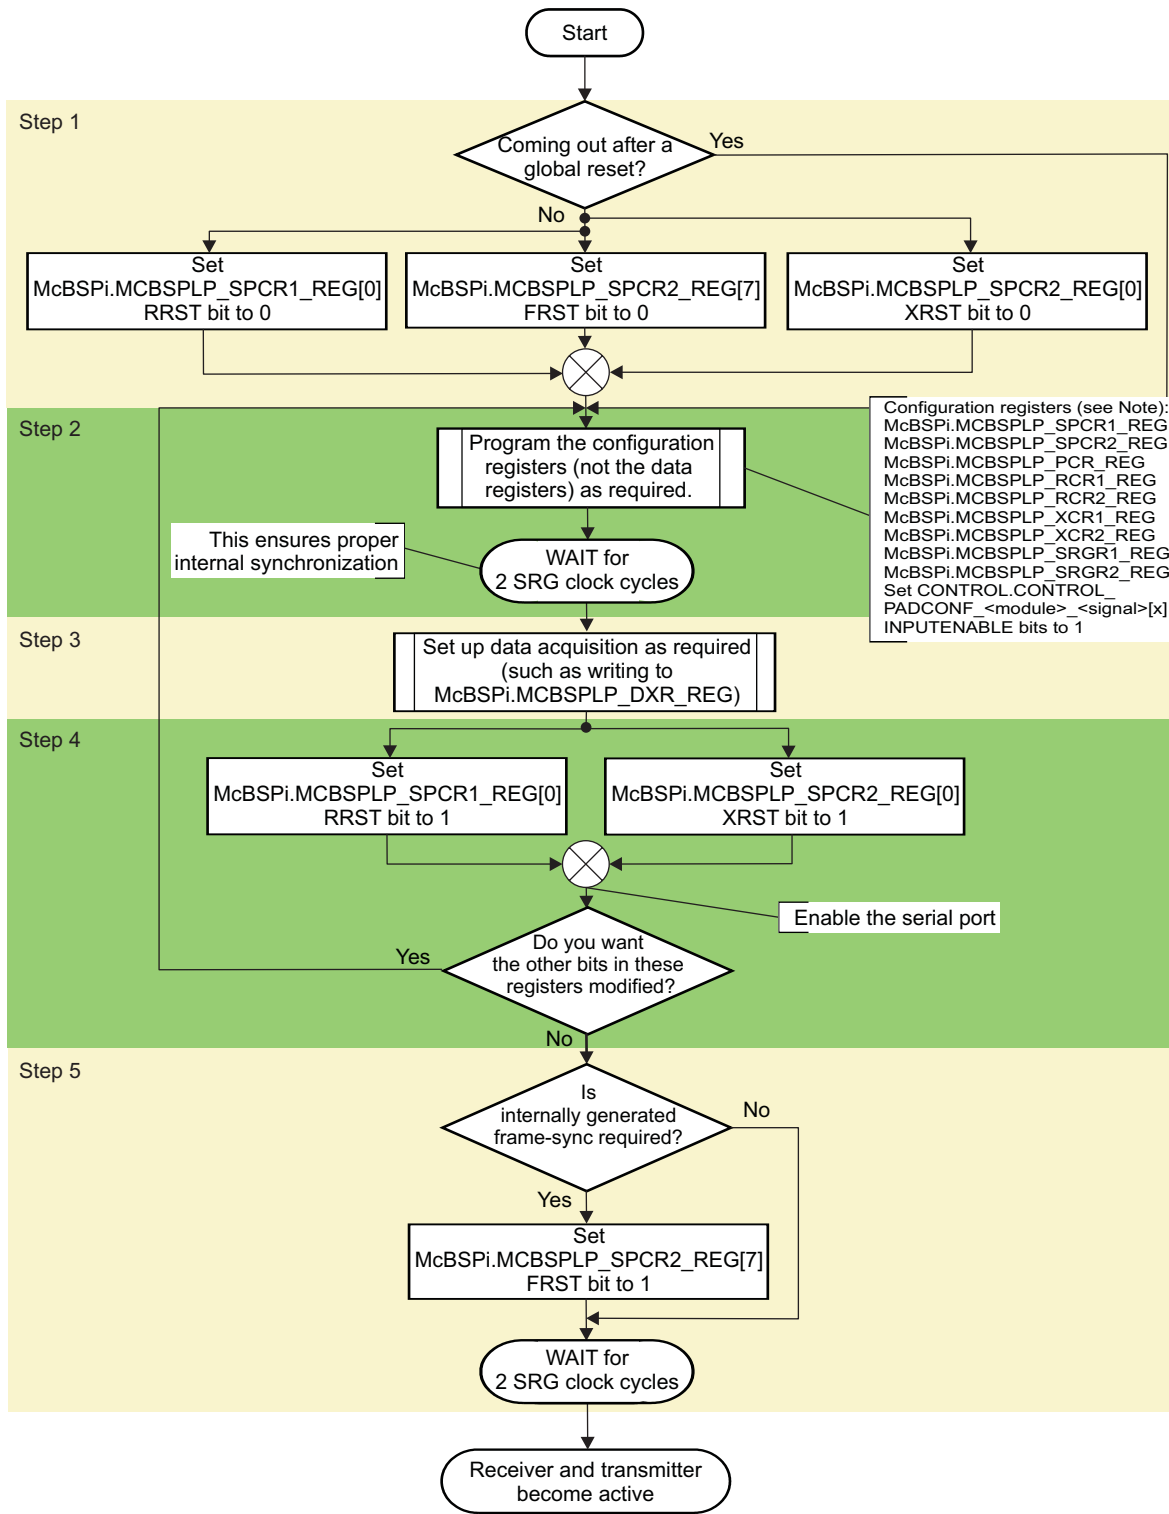

For all descriptions in this section, the McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit and the McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit are their reset value (XFULL_CYCLE bit=0 and RFULL_CYCLE bit=1).

21.5.1.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the Receiver or Transmitter has to be reset during its normal operation, and also when the Sample Rate Generator is not used for either operation.

[Figure 21-57](#) shows the serial port initialization procedure for master mode.

Figure 21-57. Flow Diagram of McBSP Initialization Procedure for Master Mode

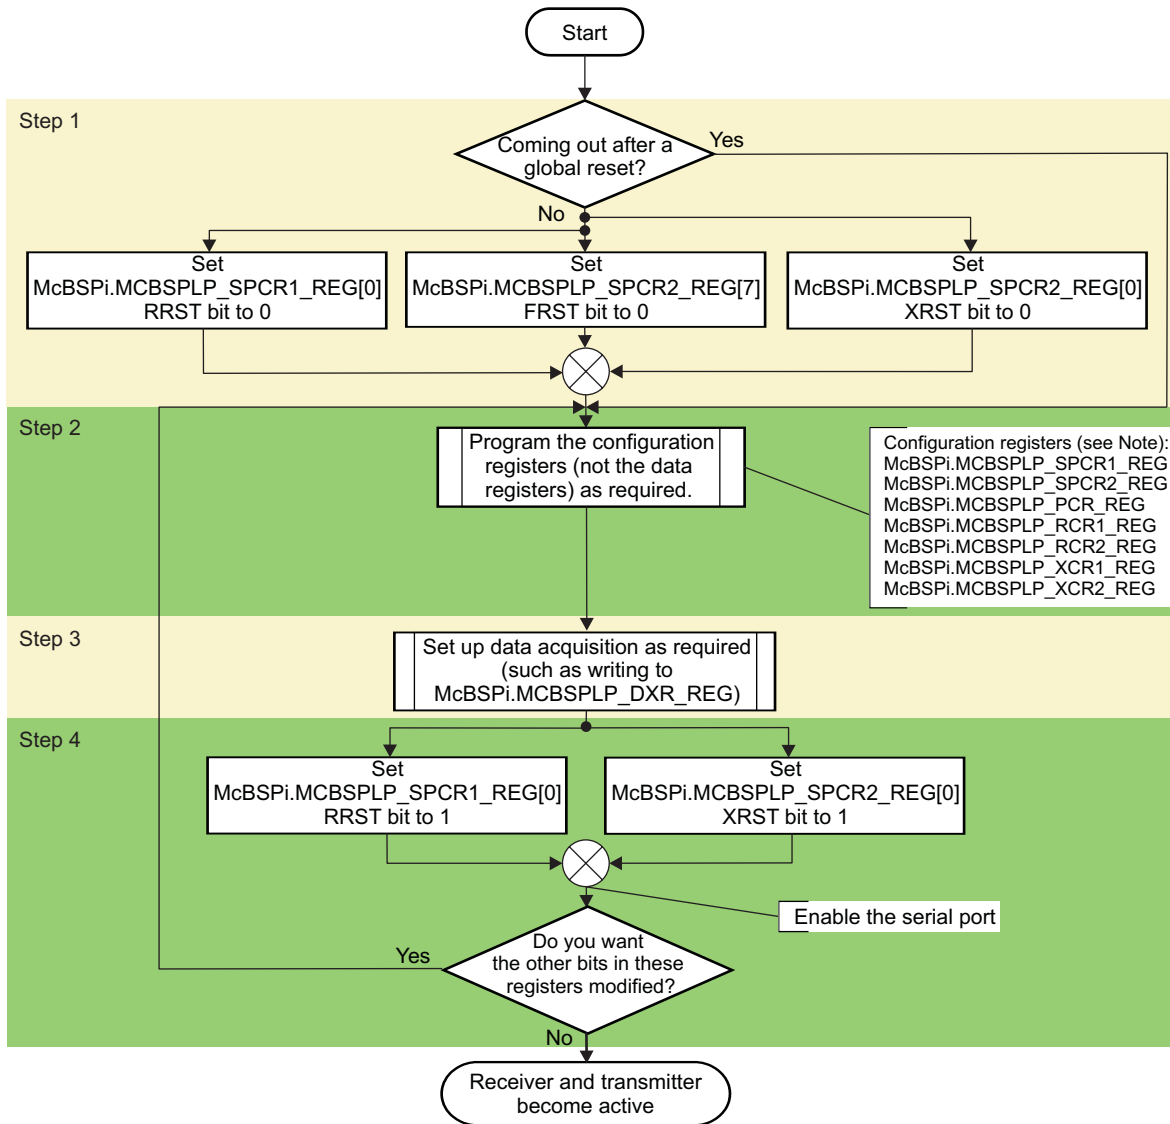

mcbsp-062

Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit and the McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit, respectively.

Figure 21-58 shows the flow diagram of the McBSP initialization procedure for slave mode.

Figure 21-58. Flow Diagram of McBSP Initialization Procedure for Slave Mode

mcbasp-074

NOTE:

- The necessary duration of the active-low period of XRST or Rrst is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP_SPCR1_REG, McBSPi.MCBSPLP_SPCR2_REG, McBSPi.MCBSPLP_PCR_REG, McBSPi.MCBSPLP_RCR1_REG, McBSPi.MCBSPLP_RCR2_REG, McBSPi.MCBSPLP_XCR1_REG, McBSPi.MCBSPLP_XCR2_REG, McBSPi.MCBSPLP_THRSH2_REG, McBSPi.MCBSPLP_XCCR_REG, McBSPi.MCBSPLP_SYSCONFIG_REG, McBSPi.MCBSPLP_SRGR1_REG, and McBSPi.MCBSPLP_SRGR2_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP_DXR_REG) should be loaded by the MPU/IVA2 subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP_MCR1_REG, McBSPi.MCBSPLP_MCR2_REG, McBSPi.MCBSPLP_RCER{A-H}_REG and McBSPi.MCBSPLP_XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- Modification on-the-fly has no effect if a reset is not done first.

21.5.1.2 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the Sample Rate Generator:

- Place the McBSP Sample Rate Generator in RESET.

During a Global RESET, the Sample Rate Generator, the Receiver, and the Transmitter reset bits (GRST, Rrst, and XRST) are automatically forced to '0'. Otherwise, during normal operation, the Sample Rate Generator can be reset by making McBSPi.MCBSPLP_SPCR2_REG[6] GRST=0, provided that CLKG and/or FSG internal signal is not used by any portion of the McBSP module. Depending on the system needs, the software may also to reset the Receiver (McBSPi.MCBSPLP_SPCR1_REG[0] Rrst=0) and reset the Transmitter (McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit =0).

- Program the registers that affect the Sample Rate Generator.

Program the Sample Rate Generator registers (McBSPi.MCBSPLP_SPCR1_REG and McBSPi.MCBSPLP_SPCR2_REG) as required for your application. Refer to [Figure 21-59](#).

If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP module (the Receiver or Transmitter) is in reset. [Table 21-24](#) presents the McBSP configuration when one of the clock sources is selected, but others registers can be impacted in function of the user application.

Table 21-24. McBSP Configuration in Function of the SRG Clock Source Selected

SRG Clock Source Selected	Module Configuration	McBSPi.MCBSPLP_PCR_REG Configuration			
		CLKRM bit ⁽¹⁾	CLKXM bit	FSRM bit ⁽¹⁾	FSXM bit
McBSPi_ICLK or CLKS	Master Transmitter and Slave Receiver	0	1	0	1
	Master Receiver and Slave Transmitter	1	0	1	0
	Master Transmitter and Receiver	1	1	1	1
CLKR	Master Transmitter and Slave Receiver	0	1	0	1
CLKX	Master Receiver and Slave Transmitter	1	0	1	0

⁽¹⁾ This configuration is correct if McBSPi.MCBSPLP_XCCR_REG[5] DLB bit=0x0. When the DLB bit is set to 1, the CLKR clock (not the mcbspi_clkr pin) is driven by the CLKX clock, which is based on the CLKXM bit.

After the Sample Rate Generator registers are programmed, wait for 2 CLKSRG cycles. This ensures proper synchronization internally.

- Enable the Sample Rate Generator (take it out of reset).

Set McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 1 to enable the Sample Rate Generator.

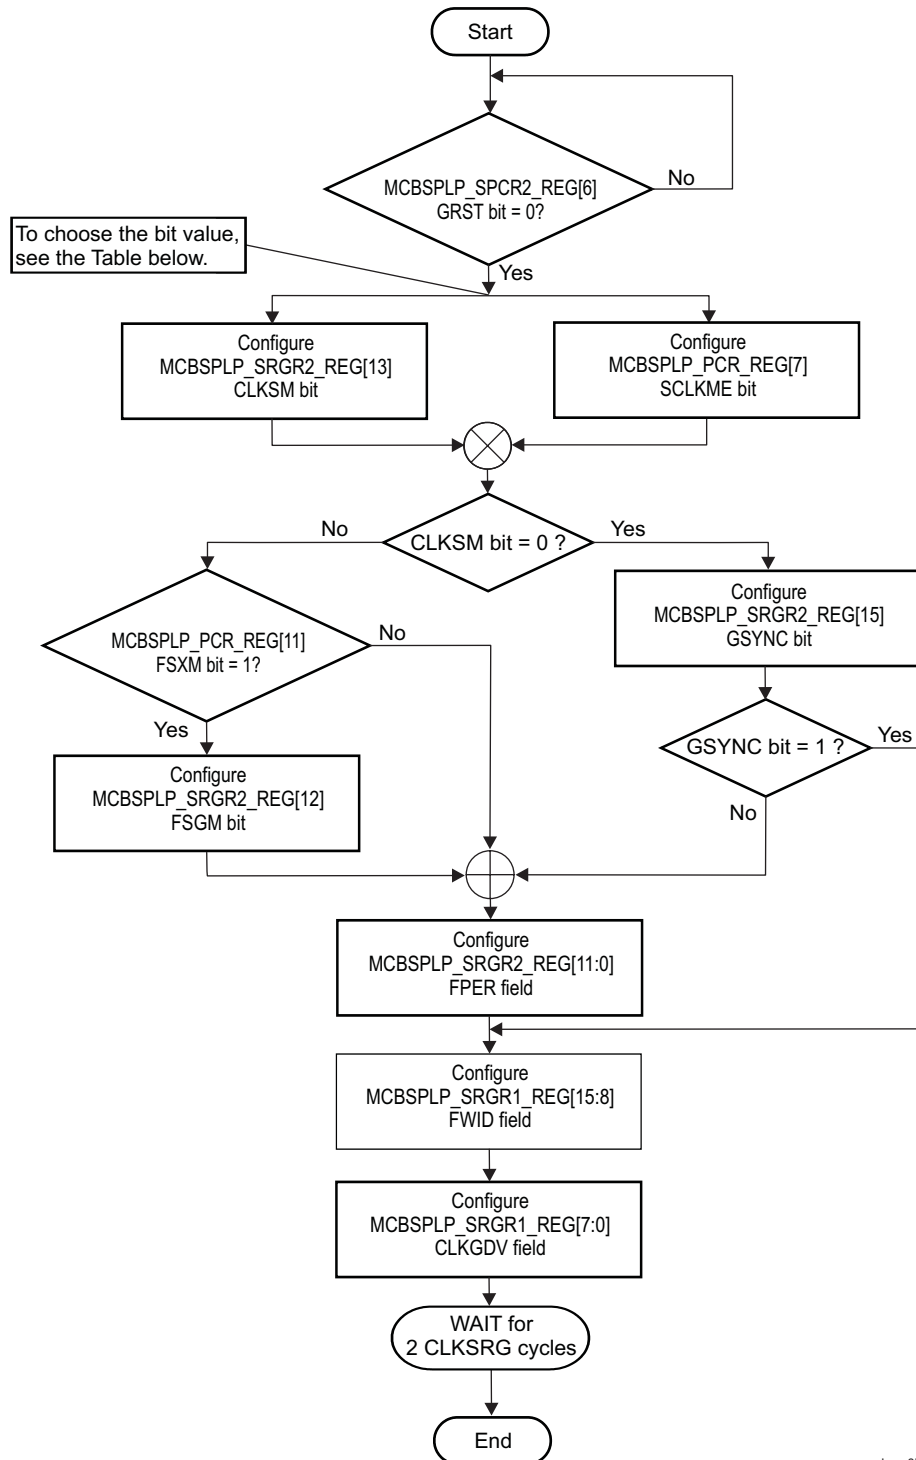

After the Sample Rate Generator is enabled, wait for 2 CLKG cycles for the Sample Rate Generator logic to stabilize.

On the next rising edge of CLKSRG, the CLKG signal transitions to '1' and starts clocking with a frequency equal to $(\text{input clock frequency}) / (\text{CLKGDV} + 1)$.

- If necessary, enable the receiver and/or the transmitter.

If necessary, remove the receiver and/or transmitter from reset by setting McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit and/or McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1.

Figure 21-59. Flow Diagram for the SRG Registers Programming

mcbsp-073

The input clock is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit in one of the following configurations (see Table 21-25):

Table 21-25. Input Clock Selection for Sample Rate Generator

SCLKME bit	CLKSM bit	Input Clock for Sample Rate Generator
0	0	Signal on mcbsp_clks pin
0	1	McBSPi_ICLK clock
1	0	Signal on mcbsp_clkr pin
1	1	Signal on mcbsp_clkx pin

21.5.1.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests (McBSPi_DMA_RX and McBSPi_DMA_TX), perform the following procedure:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1_REG value + 1 number of words, the receive DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[4] RUNDLEN bit.

- Write the transmit McBSPi.MCBSPLP_THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2_REG value + 1 number of words, the transmit DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[12] XOVLEN bit.

21.5.1.4 Interrupt Configuration

The McBSP module offers two interrupt schemes:

- L4 compliant interrupt request scheme using a common receive/transmit interrupt request line
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the common interrupt line.

21.5.1.4.1 L4-Compliant Interrupt Line

The L4-compliant interrupt line can be configured by using the McBSPi.MCBSPLP_IRQENABLE_REG register. When the McBSPi.MCBSPLP_IRQSTATUS_REG bit is set and the corresponding McBSPi.MCBSPLP_IRQENABLE_REG bit is set to one, the interrupt line is asserted. Writing one to a bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the bit.

There are several conditions, which can be configured to generate an interrupt as follows:

- Transmit buffer empty at end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF bit is set to one when a complete frame was transmitted and the transmit buffer is empty .
- Transmit buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to one when transmit buffer overflow; the data written while overflow condition is discarded).
- Transmit buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to one

- when the transmit data buffer is empty, new data needs to be transmitted).
4. Transmit buffer threshold reached (McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit is set to one when the transmit buffer free locations are equal or above the [THRSH2_REG + 1] value).
 5. Transmit end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF is set to one when a complete frame was transmitted).
 6. Transmit frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX bit is set to one when a new transmit frame synchronization is asserted).
 7. Transmit frame synchronization Error (McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR is set to one when a transmit frame synchronization error is detected).
 8. Receive buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded).
 9. Receive buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
 10. Receive buffer threshold Reached (McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set to one when the receive buffer occupied locations are equal or above the [THRSH1_REG + 1] value).
 11. Receive end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[2] REOF is set to one when a complete frame was received).
 12. Receive frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bit is set to one when a new receive frame synchronization is asserted).
 13. Receive frame synchronization error (McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR is set to one when a receive frame synchronization error is detected).

21.5.1.4.2 Legacy Interrupt Line

McBSPi_IRQ_TX and McBSPi_IRQ_RX are legacy interrupts. Not to be used for new development. McBSPi_IRQ (common interrupt line) should be preferred.

21.5.1.4.2.1 Set the receive interrupt line (legacy only)

The McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM bit field determines which event generates a receive interrupt request, McBSPi_IRQ_RX, to the MPU/IVA2.2 subsystem.

The receive interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM=0b00: The receive interrupt generated when the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit. Regardless of the value of RINTM, RRDY bit can be read to detect the RRDY=1 condition.
- RINTM = 0b01: The receive interrupt generated by an end-of-frame condition in the receive multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 0b10: The receive interrupt generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via the receive interrupt .
- RINTM = 0b11: The receive interrupt generated when McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see [Section 21.4.4.3](#).

The McBSP module also provides a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- RRDYEN is equivalent with RINTM = 0 setting

- REOFEN is equivalent with RINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- RFSREN is equivalent with RINTM = 0b10 setting
- RSYNCERREN is equivalent with RINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP_IRQSTATUS_REG.

21.5.1.4.2.2 Set the transmit interrupt line (legacy only)

The McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM bit field determines which event generates a transmit interrupt request (McBSPi_IRQ_TX) to the MPU/IVA2.2 subsystem.

The transmit interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 0b00: The transmit interrupt generated when the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit. Regardless of the value of XINTM, XRDY bit can be read to detect the XRDY=1 condition.
- XINTM = 0b01: The transmit interrupt generated by an end-of-frame condition in the transmit multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 0b10: The transmit interrupt generated by a new transmit frame-synchronization pulse. Interrupt on detection of transmit frame-synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via transmit interrupt.
- XINTM = 0b11: The transmit interrupt generated when McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR bit can be read to detect this condition. For information on using XSYNCERR bit, see [Section 21.4.4.6](#).

The McBSP module provides also a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- XDYEN is equivalent with XINTM = 0b00 setting
- XEOFEN is equivalent with XINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- XFSXEN is equivalent with XINTM = 0b10 setting
- XSYNCERREN is equivalent with XINTM = 0b11 setting

This interrupt line has its own status register, McBSPi.MCBSPLP_IRQSTATUS_REG.

21.5.1.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP receiver in reset .
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

These 3 steps are detailed in the following subsections.

21.5.1.5.1 Resetting (Step 1) and Enabling (Step 3) the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following 2 ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPLP_SPCR1_REG[0] RRST and McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits = 0,

which keeps the entire serial port in the reset state.

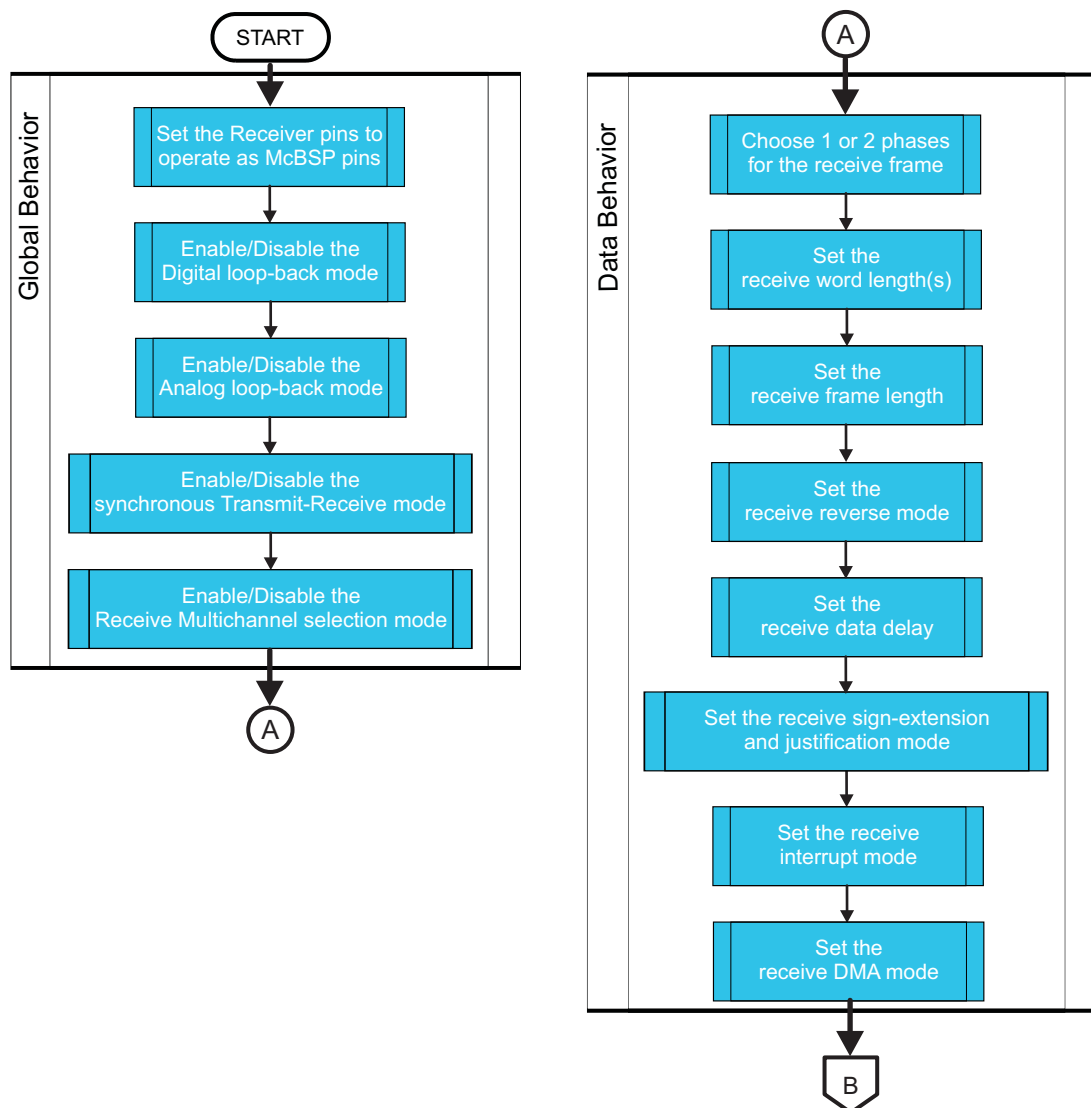

- The serial port receiver can be reset directly using the `McBSPi.MCBSPLP_SPCR1_REG[0]` RRST bit. If the SRG needs to be used, SRG must be reset directly using the `McBSPi.MCBSPLP_SPCR2_REG[6]` GRST bit. Similar operations with frame synchronization generator also require using the `McBSPi.MCBSPLP_SPCR2_REG[7]` FRST bit when the frame-sync signal must be generated.

To enable the receiver, the preceding bits, cleared to 0, must be set to 1.

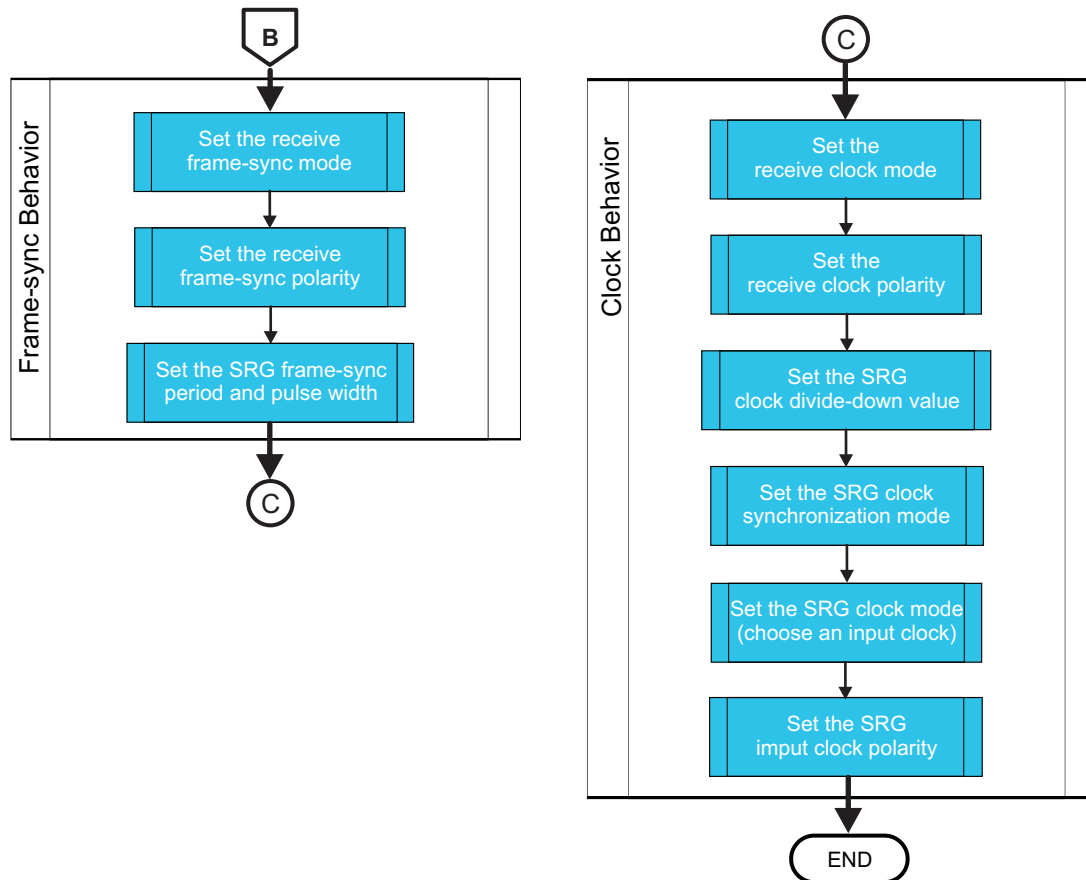

21.5.1.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

Figure 21-60 and Figure 21-61 lists important tasks to be performed when the software is configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

Figure 21-60. Important Tasks to Configure the McBSP Receiver (Part 1)

mcbasp-063

Figure 21-61. Important Tasks to Configure the McBSP Receiver (Part 2)

mcbasp-064

21.5.1.5.2.1 Global Behavior

21.5.1.5.2.1.1 Set the Receiver Pins to Operate as McBSP Pins

The McBSPi.MCBSPLP_PCR_REG[12] RIOEN bit determines whether the receiver pins are McBSP pins (RIOEN bit=0) or general-purpose I/O pins (RIOEN bit=1).

See [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

21.5.1.5.2.1.2 Enable/Disable the Digital Loop Back Mode

The McBSPi.MCBSPLP_XCCR_REG[5] DLB bit determines whether the digital loopback mode is on or off.

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals:

- DR signal is connected on DX signal to receive the transmitted data
- FSR is connected to FRX output signal
- CLKR is connected to the CLKX output signal

This mode allows testing of serial port; the McBSP module receives the data it transmits. This loopback mode is not done through pads, all output signals being disabled.

NOTE: That in digital loopback mode the SRG and the frame synchronization generator need to be enabled to generate the CLKX and FSX signals.

21.5.1.5.2.1.3 Enable/Disable the Analog Loopback Mode

The McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit determines whether the analog loopback mode is on or off.

In the analog loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals:

- DR is connected to transmit loop back data on DX input pin
- FSR is connected to FRX input pin
- CLKR is connected to the CLKX input pin

This Analog Loopback mode is also done to test the Input/Output buffers, through pads.

21.5.1.5.2.1.4 Enable/disable the synchronous transmit-receive mode (McBSP1 only)

The control registers of the System Control Module is used to configure the synchronous transmit-receive mode.

The MCBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The MCBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

21.5.1.5.2.1.5 Enable/Disable the Receive Multichannel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether the receive multichannel selection mode is on or off.

For further details, see [Section 21.4.6.5](#).

21.5.1.5.2.2 Data Behavior

21.5.1.5.2.2.1 Choose 1 or 2 Phases for the Receive Frame

The McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit determines whether the receive data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

21.5.1.5.2.2.2 Set the Receive Word Length(s)

The McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select the both length. These both bits can have values different.

21.5.1.5.2.2.3 Set the Receive Frame Length

The receive frame length is the number of serial words in the receive frame.

The McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 and McBSPi.MCBSPLP_RCR2_REG[14:8] RFLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

If a dual-phase frame is selected (RPHASE=1), the frame length must be two words (one word for phase 1 plus the one word for phase 2). Other values must not be used.

The 7-bit RFLEN1 field allows up to 128 words per phase when single-phase frame. See [Table 21-26](#) below for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFLEN fields with $[W - 1]$, where W represents the number of words per phase. For example, to get a phase length of 128 words in phase 1, load 127 words into RFLEN1.

Table 21-26. How to Calculate the Length of the Receive Frame

RPHASE	RFLEN1	RFLEN2	Frame Length
0	$0 \leq \text{RFLEN1} \leq 127$	Don't care	(RFLEN1value + 1) words
1	RFLEN1 = 0	RFLEN2 = 0	2 words

21.5.1.5.2.2.4 Set the Receive Reverse Mode

The McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For further information about reverse mode, see [Section 21.4.2.2](#).

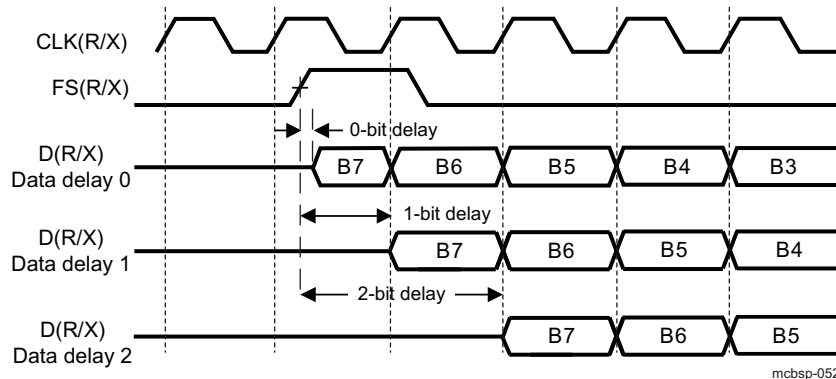

21.5.1.5.2.2.5 Set the Receive Data Delay

The McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks ($\text{RDATDLY} = 0b00\text{--}0b10$), as shown in [Figure 21-62](#) below. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 21-62. Range of Programmable Data Delay

mcbasp-052

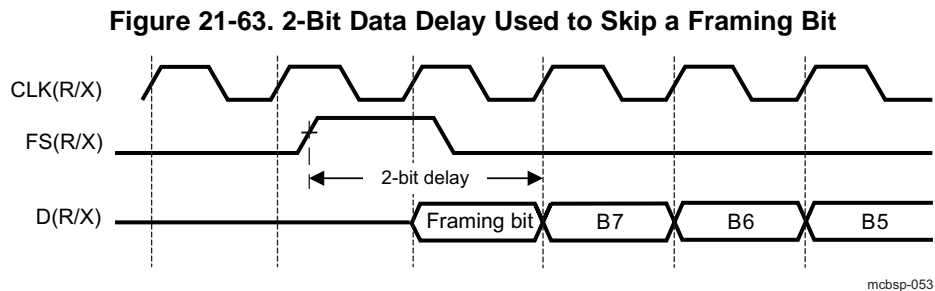

21.5.1.5.2.2.5.1 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR, and thus on mcbasp_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbasp_dx pin.

21.5.1.5.2.2.5.2 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-63. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

21.5.1.5.2.2.6 Set the Receive Sign-Extension and Justification Mode

The McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST bit field determines whether data received by the McBSP module is sign-extended or not and how it is justified.

RJUST bit selects whether data in RB is right- or left-justified (with respect to the MSB) in McBSPi.MCBSPLP_DRR_REG register and whether unused bits in McBSPi.MCBSPLP_DRR_REG are filled with zeroes or with sign bits.

Table 21-27 and Table 21-28 show the effects of various RJUST values; the effect on an example 12-bit receive-data value 0xABC, and the effect on an example 20-bit receive-data value 0xABCDE, respectively.

Table 21-27. Example: Use of RJUST Bit Field With 12-bit Data Value 0xABC

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x0000 0ABC
0b01	Right	Sign extend data into MSBs	0xFFFF FABC
0b10	Left	Zero fill LSBs	0xABC0 0000
0b11	Reserved	Reserved	Reserved

Table 21-28. Example: Use of RJUST Bit Field With 20-bit Data Value 0xABCDE

RJUST	Justification	Extension	Value in DRR_REG
0b00	Right	Zero fill MSBs	0x000A BCDE
0b01	Right	Sign extend data into MSBs	0xFFFA BCDE
0b10	Left	Zero fill LSBs	0xABCD E000

Table 21-28. Example: Use of RJUST Bit Field With 20-bit Data Value 0xABCDE (continued)

RJUST	Justification	Extension	Value in DRR_REG
0b11	Reserved	Reserved	Reserved

21.5.1.5.2.2.7 Set the Receive Interrupt Mode

Please refer to [Section 21.5.1.4.2.1](#).

21.5.1.5.2.2.8 Set the Receive DMA Mode

The McBSP receive-data DMA requests (McBSPi_DMA_RX) are active after the McBSPi.MCBSPLP_SPCR1_REG [0] RRST bit is released. After reset, the default DMA threshold (and length) is 1.

The receive DMA requests can be disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP receive data DMA requests, perform the following:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the occupied locations level in the RB is above or equal to the THRSH1_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is deasserted, and then reasserted as soon as the conditions are met again.

21.5.1.5.2.3 Frame-Sync Behavior

21.5.1.5.2.3.1 Set the Receive Frame-Sync Mode

McBSPi.MCBSPLP_PCR_REG[10] FSRM bit, McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit field are used to determine the source for receive frame synchronization and the function of the mcbbsp_fsr pin.

[Table 21-29](#) below shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the mcbbsp_fsr pin. The polarity of the signal on the mcbbsp_fsr pin is determined by the McBSPi.MCBSPLP_PCR_REG[2] FSRP bit.

Table 21-29. FSRM and GSYNC Effects on Frame-Sync Signal and mcbbsp_fsr Pin

FSRM	GSYNC	Source of Receive Frame Synchronization	MCBSPLP.FSR Pin Status
0	0 or 1	An external frame synchronization signal enters the McBSP module through the mcbbsp_fsr pin. The signal is then inverted as determined by FSRP bit before being used as internal FSR.	Input
1	0	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Output. FSG is inverted as determined by FSRP bit before being driven out on the mcbbsp_fsr pin.
1	1	Internal FSR is driven by the SRG frame-synchronization signal (FSG).	Input. The external frame-synchronization input on the mcbbsp_fsr pin is used to synchronize CLKG and generate FSG pulses.

In digital loop-back mode (DLB=1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the analog loop back mode (ALB=1), the internal receive clock signal (CLKR), and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

For more details on clock and frame-sync configuration, see [Section 21.4.3](#).

21.5.1.5.2.3.2 Set the Receive Frame-Sync Polarity

The `McBSPi.MCBSPLP_PCR_REG[2]` FSRP bit determines whether frame-synchronization pulses are active high or active low on the `mcbsp_fsr` pin.

Receive frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the `McBSPi.MCBSPLP_PCR_REG[10]` FSRM bit. FSR is also affected by the `McBSPi.MCBSPLP_SRGR2_REG[15]` GSYNC bit. For information about the effects of FSRM and GSYNC, see [Section 21.5.1.5.2.3.1](#), *Set the Receive Frame-Sync Mode*.

When FSR and FSX are inputs (`FSXM = FSRM = 0`, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the `mcbsp_dr` pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the `mcbsp_dx` pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP bit fields in the pin control register (`McBSPi.MCBSPLP_PCR_REG`) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and `FSRP = FSXP = 1`, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and `GSYNC = 0`) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit `FS(R/X)P = 1`, before being sent to the FS(R/X) pin.

[Figure 21-64](#) shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 21-64. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge

21.5.1.5.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

The SRG can produce a clock signal, CLKG, and FSG. If the SRG is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

`McBSPi.MCBSPLP_SRGR2_REG[11:0]` FPER bit field is used to set the SRG frame-sync period and `McBSPi.MCBSPLP_SRGR1_REG[15:8]` FWID bit field is used to set the SRG pulse width.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is $(FPER+1)$ CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When `GSYNC=1`, FPER is a don't care value.

Each pulse on FSG has a width of $(FWID+1)$ CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

Figure 21-65 shows a frame-synchronization period of 16 CLKG periods (FPER=15 or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods (FWID=1).

When the SRG comes out of reset, FSG is in its inactive state. Then, when GRST=1 and FSGM=1, a frame-synchronization pulse is generated. The frame width value (FWID+1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER+1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

21.5.1.5.2.4 Clock Behavior

21.5.1.5.2.4.1 Set the receive clock mode

McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit are used to set the receive clock mode.

Table 21-30 shows how to select various sources to provide the receive clock signal and affect the mcbasp_clkr pin. The McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit determines the polarity of the signal on the mcbasp_clkr pin.

Table 21-30. CLKRM Effect on Receive Clock Signal and mcbasp_clkr Pin

CLKRM	Source of Receive Clock	mcbasp_clkr Pin Status
0	The mcbasp_clkr pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP bit before being used.	Input
1	The SRG clock (CLKG) drives internal CLKR.	Output. CLKG, inverted as determined by CLKRP, is driven out on the mcbasp_clkr pin.

In the digital loop-back mode (DLB = 1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal. For more details on clock configuration, see Section 21.4.3.1.

21.5.1.5.2.4.2 Set the Receive Clock Polarity

McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit is used to set the receive clock polarity.

The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP = 1 and external clocking is selected (CLKRM = 0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP = 1 and internal clocking is selected (CLKRM = 1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbasp_clkr pin.

NOTE: CLKRP = CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

21.5.1.5.2.4.3 Set the SRG Clock Divide-Down Value

McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field is used to set the SRG clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to $1/(\text{CLKGDV} + 1)$ of SRG input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50 percent.

21.5.1.5.2.4.4 Set the SRG Clock Synchronization Mode

McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is used to set the SRG clock synchronization mode.

For more information about the clock synchronization feature, see [Section 21.4.3](#).

21.5.1.5.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit are used to set the SRG clock mode.

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

For further details about the clock synchronization feature, see [Section 21.4.3](#).

21.5.1.5.2.4.6 Set the SRG Input Clock Polarity

McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP bit, McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit and McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit are used to set the SRG input clock polarity.

The SRG can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the SRG must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the mcbbsp_clks, mcbbsp_clkx, or mcbbsp_clkr pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the mcbbsp_clks pin, CLKXP for the mcbbsp_clkx pin, CLKRP for the mcbbsp_clkr pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

21.5.1.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter operation
3. Take the transmitter out of reset

These 3 steps are described in more details in the sub-sections below.

21.5.1.6.1 Resetting (Step 1) and Enabling (Step 3) the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset).

The serial port can be reset in the following two ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPLP_SPCR1_REG[0] RRST and McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.
2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit. Similar operation with the Frame Synchronization

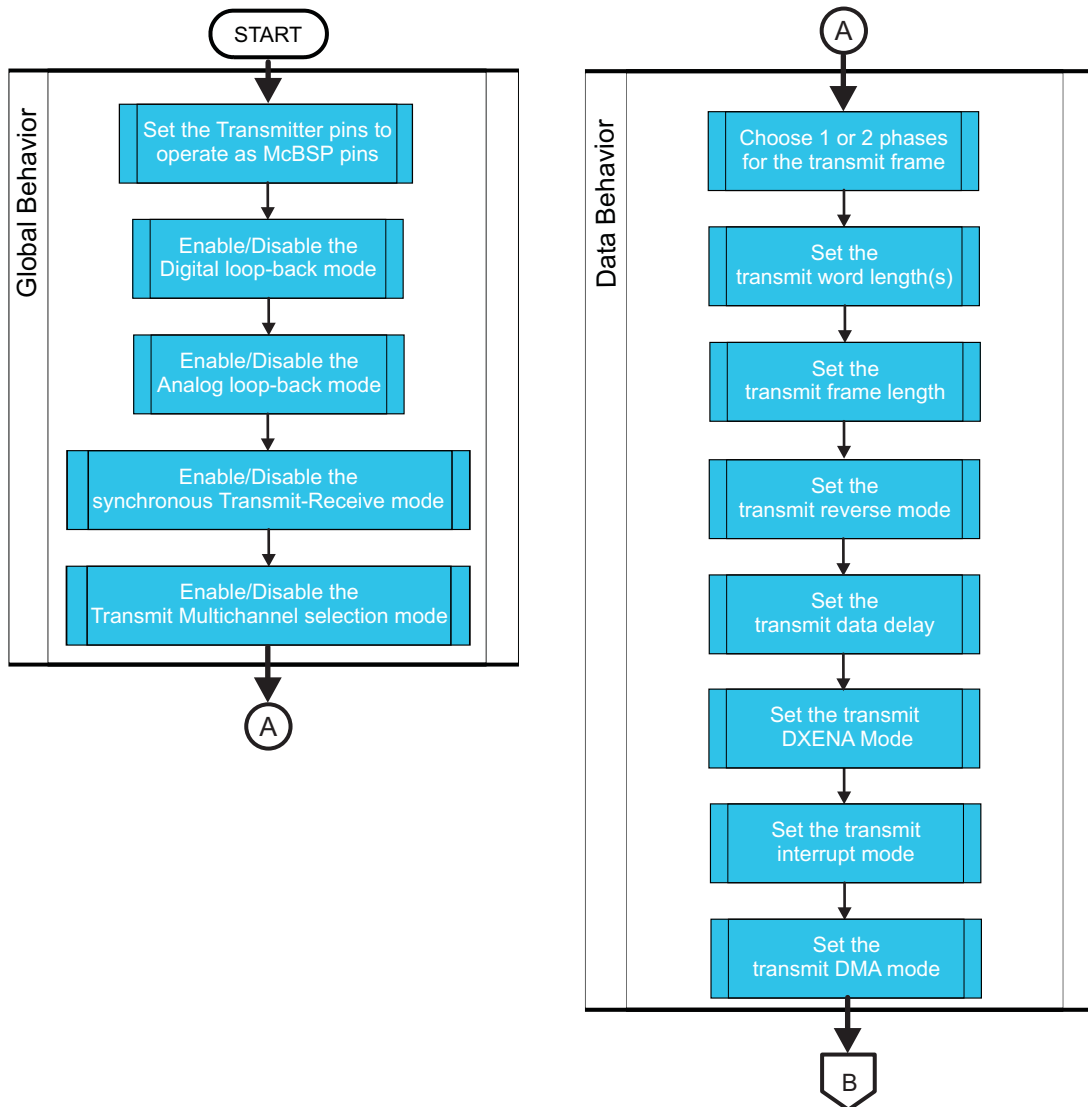

Generator also requires using the `McBSPi.MCBSPLP_SPCR2_REG[7]` FRST bit when the frame-sync signal must be generated.

To enable the transmitter, the preceding bits, cleared to 0, must be set to 1.

21.5.1.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

Figure 21-66 and Figure 21-67 list important tasks to be performed when configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

Figure 21-66. Important Tasks to Configure the McBSP Transmitter (Part 1)

mcbasp-065

Figure 21-67. Important Tasks to Configure the McBSP Transmitter (Part 2)

mcbasp-066

21.5.1.6.2.1 Global Behavior

21.5.1.6.2.1.1 Set the Transmitter Pins to Operate as McBSP Pins

McBSPi.MCBSPLP_PCR_REG[13] XIOEN bit determines whether the transmitter pins are McBSP pins (XIOEN=0) or general-purpose I/O pins (XIOEN=1).

See [Section 21.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

21.5.1.6.2.1.2 Enable/Disable the Digital Loop-Back Mode

See [Section 21.5.1.5.2.1.2](#).

21.5.1.6.2.1.3 Enable/Disable the Analog Loop-Back Mode

See [Section 21.5.1.5.2.1.3](#).

21.5.1.6.2.1.4 Enable/Disable the Synchronous Transmit-Receive Mode (McBSP1 only)

See [Section 21.5.1.5.2.1.4](#).

21.5.1.6.2.1.5 Enable/Disable the Transmit Multichannel Selection

McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field determines whether the transmit multichannel selection mode is on or off.

See [Section 21.4.6.7](#).

21.5.1.6.2.2 Data Behavior

21.5.1.6.2.2.1 Choose 1 or 2 Phases for the Transmit Frame

McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit determines whether the transmit data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

21.5.1.6.2.2.2 Set the Transmit Word Length(s)

McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

If a single-phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select the both length. These both bits can have values different.

21.5.1.6.2.2.3 Set the Transmit Frame Length

The transmit frame length is the number of serial words in the transmit frame.

McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 and McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

If a dual-phase frame is selected (XPHASE=1), the frame length is 2 words, the length of phase 1 (one word) plus the length of phase 2 (one word). Others values must not be used.

The 7-bit XFRLEN fields allow up to 128 words per phase. See [Table 21-31](#) for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the XFRLEN fields with [W minus 1], where W represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 21-31. How to Calculate the Length of the Transmit Frame

XPHASE	XFRLEN1	XFRLEN2	Frame Length
0	$0 \leq \text{XFRLEN1} \leq 127$	Don't care	(XFRLEN1value +1) words
1	XFRLEN1= 0	XFRLEN2 = 0	2 words

21.5.1.6.2.2.4 Set the Transmit Reverse Mode

McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For additional information about reverse mode, see [Section 21.4.2.2](#).

21.5.1.6.2.2.5 Set the Transmit Data Delay

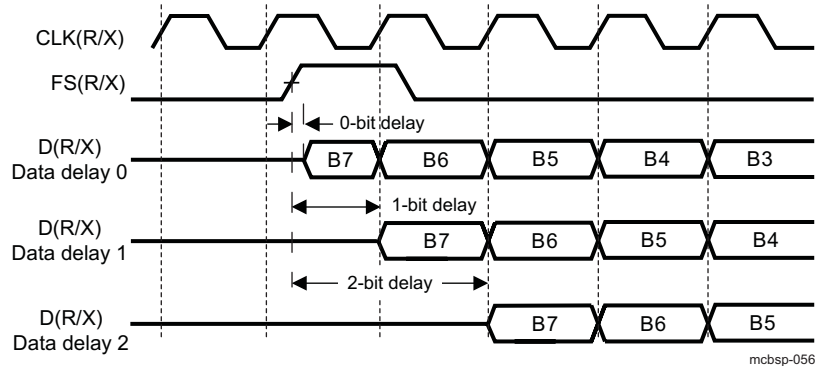

McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (XDATDLY=00b–10b), as shown in Figure 21-68. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

NOTE: Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 21-68. Range of Programmable Data Delay

21.5.1.6.2.2.5.1 0-Bit Data Delay:

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on mcbspi_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbbsp_dx pin.

21.5.1.6.2.2.5.2 2-Bit Data Delay:

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 21-69. The data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 21-69. 2-Bit Data Delay Used to Skip a Framing Bit

21.5.1.6.2.2.6 Set the Transmit DXENA Mode

McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the mcbbsp_dx pin. Set DXENA to enable an extra delay for turn-on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 13 ns, 18 ns (default), 24 ns, or 30 ns can be set using the McBSPi.MCBSPLP_XCCR_REG[13:12] DXENDLY bit field. If you tie together the mcbbsp_dx pins of multiple McBSP modules, make sure DXENA = 1, to avoid having more than one McBSP transmitting on the data line at one time.

21.5.1.6.2.7 Set the Transmit Interrupt Mode

See [Section 21.5.1.4.2.2](#).

21.5.1.6.2.8 Set the Transmit DMA Mode

The McBSP transmit data DMA requests (McBSPi_DMA_TX) are active after the transmit McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit is released. After reset, the default DMA threshold (and length) is 1.

The transmit DMA requests can be disabled by setting the McBSPi.MCBSPLP_XCCR_REG[3] XDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP transmit data DMA requests, follow this procedure:

- Write the transmit McBSPi.MCBSPLP_THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the free locations level in XB is above or equal to the THRSH2_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH2_REG value + 1) number of words, the transmit DMA request is deasserted, and then reasserted as soon as the conditions are met again.

21.5.1.6.2.3 Frame-Synchronization Behavior

21.5.1.6.2.3.1 Set the Transmit Frame-Sync Mode

McBSPi.MCBSPLP_PCR_REG[11] FSXM bit and McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit are used to set the transmit frame-sync mode.

[Table 21-32](#) shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

1. External frame-synchronization input
2. Sample rate generator frame-synchronization signal (FSG)
3. Sample rate generator frame-synchronization signal (FSG) gated by the transmit buffer XB empty condition.

[Table 21-32](#) also shows the effect of each bit setting on the mcbbsp_fsx pin. The FSXP bit determines the polarity of the signal on the mcbbsp_fsx pin.

Table 21-32. How FSXM and FSGM Select the Source of Transmit Frame-Sync Pulses

FSXM	FSGM	Source of Transmit Frame Synchronization	mcbbsp_fsx Pin Status
0	0 or 1	An external FSG enters the McBSP through the mcbbsp_fsx pin. The signal is then inverted by FSXP bit before being used as internal FSX.	Input
1	1	Internal FSX is driven by the SRG FSG.	Output. FSG is inverted by FSXP bit before being driven out on mcbbsp_fsx pin.
1	0	A XB empty condition causes the McBSP not to generate a transmit frame-synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER bits as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated.	Output. The generated frame-synchronization pulse is inverted as determined by FSXP bit before being driven out on mcbbsp_fsx pin.

If the SRG creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the `mcbsp_fsr` pin. For more details, see [Section 21.4.3.3](#).

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on frame-sync configuration, see [Section 21.4.3.2](#).

21.5.1.6.2.3.2 Set the Transmit Frame-Sync Polarity

`McBSPi.MCBSPLP_PCR_REG[3]` FSXP bit determines whether frame-synchronization pulses are active high or active low on the `mcbsp_fsx` pin.

Transmit frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the `McBSPi.MCBSPLP_PCR_REG[11]` FSXM bit. FSX is also affected by the `McBSPi.MCBSPLP_SRGR2_REG[12]` FSGM bit. For information about the effects of FSXM and FSGM, see [Section 21.5.1.6.2.3.1](#)).

When FSR and FSX are inputs (FSXM=FSRM=0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the `mcbsp_dr` pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the `mcbsp_dx` pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All FSG (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP=FSXP=1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC=0) is selected and the polarity bit FS(R/X)P=1, the internal active-high FSG are inverted before being sent to the FS(R/X) pin.

21.5.1.6.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

See [Section 21.5.1.5.2.3.3](#).

21.5.1.6.2.4 Clock Behavior

21.5.1.6.2.4.1 Set the Transmit Clock Mode

The `McBSPi.MCBSPLP_PCR_REG[9]` CLKXM bit is used to set the transmit clock mode.

[Table 21-33](#) shows how the CLKXM bit selects the transmit clock and the corresponding status of the `mcbsp_clkx` pin. The CLKXP bit determines the polarity of the signal on the `mcbsp_clkx` pin.

Table 21-33. CLKXM Bit Effect on Transmit Clock and MCBSPLP.CLKX Pin

CLKXM	Source of Transmit Clock	mcbsp_clkx Pin Status
0	Internal CLKX is driven by an external clock on the <code>mcbsp_clkx</code> pin. CLKX is inverted as determined by CLKXP before being used.	Input
1	Internal CLKX is driven by the SRG clock, CLKG.	Output. CLKG, inverted as determined by CLKXP, is driven out on <code>mcbsp_clkx</code> .

If the SRG creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the `mcbsp_fsr` pin.

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on clock configuration, see [Section 21.4.3.1](#).

21.5.1.6.2.4.2 Set the Transmit Clock Polarity

The `McBSPi.MCBSPLP_PCR_REG[1]` CLKXP bit is used to set the transmit clock polarity.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP=1 and external clocking is selected (CLKXM=0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP=1 and internal clocking is selected (CLKXM=1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the `mcbsp_clkx` pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the `mcbsp_clkr` pin.

NOTE: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

21.5.1.6.2.4.3 Set the SRG Clock Divide-Down Value

See [Section 21.5.1.5.2.4.3](#).

21.5.1.6.2.4.4 Set the SRG Clock Synchronization Mode

See [Section 21.5.1.5.2.4.4](#).

21.5.1.6.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

See [Section 21.5.1.5.2.4.5](#).

21.5.1.6.2.4.6 Set the SRG Input Clock Polarity

See [Section 21.5.1.5.2.4.6](#).

21.5.1.7 General-Purpose I/O on the McBSP Pins (Legacy Only)

[Table 21-34](#) summarizes how to use the McBSP pins as general-purpose I/O pins. All the bits mentioned in the table except XRST and RRST bits are in the pin control register (`McBSPi.MCBSPLP_PCR_REG`). `McBSPi.MCBSPLP_SPCR2_REG[0]` XRST bit and `McBSPi.MCBSPLP_SPCR1_REG[0]` RRST bit are in the serial port control registers.

To use receiver pins `mcbsp_clkr`, `mcbsp_fsr`, and `mcbsp_dr` as general-purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (`McBSPi.MCBSPLP_SPCR1_REG[0]` RRST bit =0).
2. General-purpose I/O is enabled for the serial port receiver (`McBSPi.MCBSPLP_PCR_REG[12]` RIOEN=1).

The `mcbasp_clkr` and `mcbasp_fsr` pins can be individually configured as either input or output pins with the `CLKRM` and `FSRM` bits, respectively. The `mcbasp_dr` pin can only be an input pin. [Table 21-34](#) shows, which bits in `McBSPi.MCBSPLP_PCR_REG` are used to read from/write to these pins.

For the transmitter pins `mcbasp_clkx`, `mcbasp_fsx`, and `mcbasp_dx`, you must meet two conditions:

1. The transmitter of the serial port is in reset (`McBSPi.MCBSPLP_SPCR2_REG[0] XRST=0`).
2. General-purpose I/O is enabled for the serial port transmitter (`McBSPi.MCBSPLP_PCR_REG[12] XIOEN=1`).

The `mcbasp_clkx` and `mcbasp_fsx` pins can be individually configured as input or output pins with the `CLKXM` and `FSXM` bits, respectively. The `mcbasp_dx` pin can only be an output pin. [Table 21-34](#) shows the bits in `McBSPi.MCBSPLP_PCR_REG` used to read from/write to these pins.

For the `mcbasp_clks` pin (common to all McBSP modules), all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (`RRST=0` and `XRST=0`).
2. General-purpose I/O is enabled for both the receiver and the transmitter (`RIOEN=1` and `XIOEN=1`).

The `mcbasp_clks` pin can only be an input pin. To read the status of the signal on the `mcbasp_clks` pin, read the `McBSPi.MCBSPLP_PCR_REG[6] CLKS_STAT` bit.

Table 21-34. Using McBSP Pins for General-Purpose I/O

Pin	General-Purpose use enabled by this bit combination	Selected as output when	Output value driven from this bit	Selected as input when	Input value read from this bit
<code>mcbasp_clkx</code>	<code>XRST = 0</code> <code>XIOEN = 1</code>	<code>CLKXM = 1</code>	<code>CLKXP</code>	<code>CLKXM = 0</code>	<code>CLKXP</code>
<code>mcbasp_fsx</code>	<code>XRST = 0</code> <code>XIOEN = 1</code>	<code>FSXM = 1</code>	<code>FSXP</code>	<code>FSXM = 0</code>	<code>FSXP</code>
<code>mcbasp_dx</code>	<code>XRST = 0</code> <code>XIOEN = 1</code>	Always	<code>DX_STAT</code>	Never	Does not apply
<code>mcbasp_clkr</code>	<code>RRST = 0</code> <code>RIOEN = 1</code>	<code>CLKRM = 1</code>	<code>CLKRP</code>	<code>CLKRM = 0</code>	<code>CLKRP</code>
<code>mcbasp_fsr</code>	<code>RRST = 0</code> <code>RIOEN = 1</code>	<code>FSRM = 1</code>	<code>FSRP</code>	<code>FSRM = 0</code>	<code>FSRP</code>
<code>mcbasp_dr</code>	<code>RRST = 0</code> <code>RIOEN = 1</code>	Never	Does not apply	Always	<code>DR_STAT</code>
<code>mcbasp_clks</code>	<code>RRST = XRST = 0</code> <code>RIOEN = XIOEN = 1</code>	Never	Does not apply	Always	<code>CLKS_STAT</code>

21.5.1.8 Data Packing Examples

This section describes two ways to implement data packing in the McBSP: Using frame length and word length, and using word length and ignoring frame sync pulses.

21.5.1.8.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to pack data effectively. For example, four 8-bit words are transferred in a single-phase frame, as shown in [Figure 21-70](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 00011b: 4-word frame
- (R/X)WDLEN1 = 101b: 32-bit words

Four 8-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, four reads from `McBSPi.MCBSPLP_DRR_REG` and four writes to `McBSPi.MCBSPLP_DXR_REG` are necessary for each frame.

Figure 21-70. Four 8-bit Data Words Transferred To/From McBSP Module

This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in [Figure 21-71](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 0000000b: 1-word frame
- (R/X)WDLLEN1 = 000b: 8-bit words

Two 16-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, two reads from `McBSPi.MCBSPLP_DRR_REG` and two writes to `McBSPi.MCBSPLP_DX_REG` are necessary for each frame. This results in only half the number of transfers, as compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

Figure 21-71. One 32-bit Data Word Transferred To/From McBSP Module

21.5.1.8.2 Data Packing Using Word Length and the Frame-Sync Ignore Function

When there are multiple words per frame, data can be packed by increasing the word length (defining a serial word with more bits) and by ignoring frame-sync pulses. [Figure 21-72](#) shows the McBSP operating at the maximum packet frequency. Here, each frame has only one 8-bit word. Notice the frame-sync pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

Figure 21-72. 8-bit Data Words Transferred at Maximum Packet Frequency

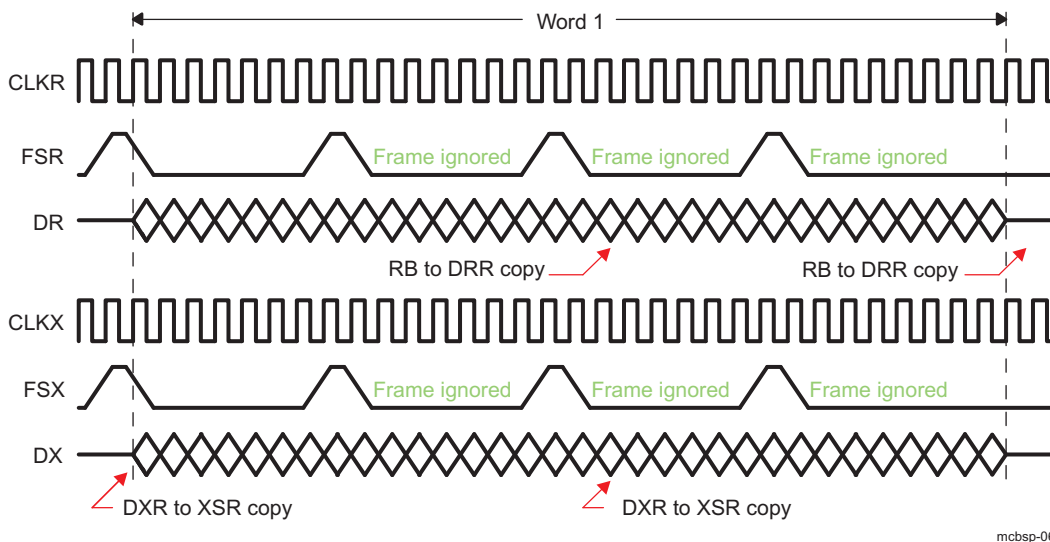

Figure 21-73 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-sync pulse. However, the McBSP ignores subsequent pulses. Only one read transfer or one write transfer is required every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth the bandwidth needed to transfer four 8-bit words.

Figure 21-73. Configuring the Data Stream as a Continuous 32-bit Word

21.5.2 SIDETONE Feature

21.5.2.1 SIDETONE Activation Procedure

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel mode of the McBSP module:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set to 1 the McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit, to select multichannel mode enable.
- Set a frame length (McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 bit field and McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see the note

below).

- Select the input/output channels configured as SIDETONE channels by setting the following bit fields listed in [Table 21-35](#):

Table 21-35. Selection of the SIDETONE Input and Output Channels

Bit field	Description
McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN	Map the CH1 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN	Map the CH0 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels)
McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN	Map the CH1 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)
McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN	Map the CH0 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels)

- Enable SIDETONE by setting 2 bits to 1:
 1. In McBSP module, the McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit
 2. In SIDETONE core, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

21.5.2.2 SIDETONE Initialization Procedure

The SIDETONE core initialization procedure is as follows:

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable loading of the FIR coefficients.
2. Load one by one the FIR coefficients performing 128 write accesses to McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field, the McBSPi.ST_SFIRCR_REG[0] FIRCOEFF bit is loaded first. To ensure the completion of loading, check the status bit-field, McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit.
3. Set-up gain values for both channels writing desired values inside McBSPi.ST_SGAINCR_REG[31:16] CH1GAIN bit field for the second sidetone channel and McBSPi.ST_SGAINCR_REG[15:0] CH0GAIN bit field for the first sidetone channel.

21.5.2.3 SIDETONE FIR Coefficients Writing

Writing the coefficients is only possible when the SIDETONE is disabled.

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable writing of the FIR coefficients, or write 0, and then write 1 in the COEFFWREN bit to reset the write process.
2. Perform 128 write accesses in 32/16 LSB bit mode on the McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. The first write action following the previous step sets the coefficient index 0.
3. Check that the write is done by reading McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit (it becomes 1 after the 128th coefficient is written).

21.5.2.4 SIDETONE FIR Coefficients Reading

Reading the coefficients is only possible when the SIDETONE is disabled.

- Write 0 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable reading of the FIR coefficients, or write 1, and then write 0 in the COEFFWREN bit to reset the read process.
- Perform 128 read accesses from McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. Each read returns coefficients one by one. The first read following previous step returns coefficient index 0.

21.6 McBSP Register Manual

Table 21-36 shows the base address and address space for the McBSP module instances.

Table 21-36. McBSP Instance Summary

Module Name	Base Address (hex)	Size
McBSP1	0x4807 4000	4K bytes
McBSP5	0x4809 6000	4K bytes
McBSP2	0x4902 2000	4K bytes
McBSP3	0x4902 4000	4K bytes
McBSP4	0x4902 6000	4K bytes
SIDETONE_McBSP2	0x4902 8000	4K bytes
SIDETONE_McBSP3	0x4902 A000	4K bytes

21.6.1 McBSP Register Mapping Summary

CAUTION

The McBSP data registers (that is, DXR_REG for data transmit and DRR_REG for data receive) support 8-, 16-, and 32-bit data accesses. All other McBSP registers are limited to 32-bit data accesses; 16- and 8-bit data accesses are not allowed and can corrupt register contents.

Table 21-37. McBSP1 Registers Mapping Summary

Register Name	Type	Register Width (Bits)	Address Offset	Physical Address

RESERVED																FREE	SOFT	FRST	GRST	XINTM	XSYNCERR	XEMPTY	XRDY	XRST							

Bits	Field Name	Description	Type	Reset
31:10	RESERVED	Read returns 0x0.	R	0x000000
9	FREE	Free Running Mode (When this bit is set, the module ignores the Msuspend input) 0x0: Free running mode is disabled 0x1: Free running mode is enabled	RW	0x0
8	SOFT	Soft Bit 0x0: SOFT Mode is disabled: the McBSP module stops its activity immediately following MSuspend assertion. 0x1: SOFT Mode is enabled: the McBSP module freezes its state after completion of the current operation when MSuspend is asserted.	RW	0x0
7	FRST	Frame-Sync Generator Reset 0x0: Frame-synchronization logic is reset. Frame-sync signal FSG is not generated by the sample-rate generator 0x1: Frame-sync signal FSG is generated after (FPER+1) number of CLKG clocks; i.e., all frame counters are loaded with their programmed values	RW	0x0
6	GRST	Sample-Rate Generator Reset 0x0: SRG is reset 0x1: SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2])	RW	0x0
5:4	XINTM	Transmit Interrupt Mode (legacy) 0x0: Transmit interrupt is driven by XRDY 0x1: Transmit interrupt generated by end-of-frame 0x2: Transmit interrupt generated by a new frame synchronization 0x3: Transmit interrupt generated by XSYNCERR	RW	0x0
3	XSYNCERR	Transmit Synchronization Error (writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0x0
2	XEMPTY	Transmit Shift Register XSR Empty 0x0: XSR is empty 0x1: XSR is not empty	R	0x0
1	XRDY	Transmitter ready 0x0: Transmitter is not ready. 0x1: Transmitter is ready for new data in DXR	R	0x0
0	XRST	Transmitter reset. This resets and enables the transmitter. 0x0: The serial port transmitter is disabled and in reset state. 0x1: The serial port transmitter is enabled.	RW	0x0

Bits	Field Name	Description	Type	Reset
14:13	RJUST	Receive Sign-Extension and Justification Mode 0x0: Right-justify and zero-fill MSBs in DRR 0x1: Right-justify and sign-extend MSBs in DRR 0x2: Left-justify and zero-fill LSBs in DRR 0x3: Reserved	RW	0x0
12:8	RESERVED	Read returns 0x0.	R	0x00
7	DXENA	DX Enabler 0x0: DX enabler is off 0x1: DX enabler is on	RW	0x0
6	RESERVED	Read returns 0x0.	R	0x0
5:4	RINTM	Receive Interrupt Mode (legacy) 0x0: Receive Interrupt driven by RRDY (i.e. end of word) and end of frame in A-bis mode 0x1: Receive Interrupt generated by end-of-block or end-of-frame in multichannel operation 0x2: Receive Interrupt generated by a new frame synchronization 0x3: Receive Interrupt generated by RSYNCERR	RW	0x0
3	RSYNCERR	Receive Synchronization Error (writing 0 to this bit clear the legacy receive interrupt if asserted due to RSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP	RW	0x0
2	RFULL	Receive Shift Register (RSR) Full 0x0: DRR is not read, RB is full and RSR is also full with new word 0x1: RB is not in overrun condition	R	0x0
1	RRDY	Receiver Ready 0x0: Receiver is not ready 0x1: Receiver is ready with data to be read from DRR	R	0x0
0	RRST	Receiver reset. This resets and enables the receiver. 0x0: The serial port receiver is disabled and in reset state. 0x1: The serial port receiver is enabled.	RW	0x0

RESERVED																GSYNC	CLKSP	CLKSM	FSGM	FPER												

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0x0.	R	0x0000
15	GSYNC	Sample Rate Generator Synchronization Only used when the external clock (CLKS) drives the SRG clock (CLKSM=0) 0x0: The SRG clock (CLKG) is free running. 0x1: The SRG clock (CLKG) is running. But CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR). Also, frame period, FPER, is a don't care because the period is dictated by the external frame-sync pulse.	RW	0x0
14	CLKSP	CLKS Polarity Clock Edge Select Only used when the external clock CLKS drives the SRG clock (CLKSM=0). 0x0: Rising edge of CLKG and FSG. 0x1: Falling edge of CLKG and FSG.	RW	0x0
13	CLKSM	McBSP SRG Clock Mode 0x0: SCLKME=0: SRG clock derived from the CLKS pin. SCLKME=1: SRG clock derived from the CLKR input pin. 0x1: SCLKME=0: SRG clock derived from the McBSPi_ICLK clock. SCLKME=1: SRG clock derived from the CLKX input pin.	RW	0x1
12	FSGM	Sample Rate Generator Transmit Frame-Synchronization Mode Used when FSXM=1 in the PCR. 0x0: Transmit frame-sync signal (FSX) is generated when transmit buffer is not empty. When FSGM=0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). 0x1: Transmit frame-sync signal driven by the SRG frame-sync signal, FSG.	RW	0x0
11:0	FPER	Frame Period. This value + 1 determines when the next frame-sync signal becomes active. Range: 1 to 4096 CLKG periods	RW	0x000

Description	McBSP_LP transmit buffer threshold (DMA or IRQ trigger)		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																XTHRESHOLD															

Bits	Field Name	Description	Type	Reset
31:11	RESERVED	Read returns 0x0.	R	0x000000
10:0 ⁽¹⁾	XTHRESHOLD	Transmit buffer threshold value. The DMA request (if enabled) of interrupt assertion (if enabled) is triggered if the number of free locations in the transmit buffer are above or equal to the XTHRESHOLD value + 1. Also, this value (XTHRESHOLD value + 1) indicates the number of words transferred during a transmit data DMA request, if transmit DMA is enabled.	RW	0x00

⁽¹⁾ XTHRESHOLD is an 11-bit field for McBSP2 only. For other McBSPs, XTHRESHOLD is an 8-bit field (bits 7 to 10 are reserved). In other words, the other McBSPs are limited to a FIFO width of 0x7F.

Description	McBSP_LP transmit configuration control register		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																EXTCLKGATE	PPCONNECT	DXENDLY	XFULL_CYCLE	RESERVED						DLB	RESERVED	XDMAEN	RESERVED	XDISABLE	

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Read returns 0x0.	R	0x0000
15	EXTCLKGATE	External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0x0: External clock gating disabled. 0x1: External clock gating enable.	RW	0x0
14	PPCONNECT	Pair to pair connection. When set the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. 0x0: non Pair-to-pair connection. The DX pin will go to high-impedance state when there is no frame to transmit. 0x1: Pair-to-pair connection. When set, the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. This means the DX pin will be driven outside valid frame window. In that case, data sent by McBSP module during inactive channel are not guaranteed.	RW	0x0
13:12	DXENDLY	When McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is set to one, this field selects the added delay as follow: 0x0: 13 ns 0x1: 18 ns (default) 0x2: 24 ns 0x3: 30 ns	RW	0x1
11	XFULL_CYCLE	Transmit full cycle mode select: 0x0: McBSP module operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data) 0x1: McBSP module operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data)	RW	0x0
10:6	RESERVED	Read returns 0x0.	R	0x00
5	DLB	Digital Loop-Back 0x0: No DLB 0x1: DLB	RW	0x0
4	RESERVED	Read returns 0x0.	R	0x0

Bits	Field Name	Description	Type	Reset
3	XDMAEN	Transmit DMA Enable bit. When set to zero this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset. 0x0: When set to zero this bit will gate the external transmit DMA request, 0x1: When set to one this bit will NOT gate the external transmit DMA request,	RW	0x1
2:1	RESERVED	Read returns 0x0.	R	0x0
0	XDISABLE	Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary. 0x0: The transmit process will NOT stop at the next frame boundary. 0x1: The transmit process will stop at the next frame boundary.	RW	0x0

High-Speed USB Host Subsystem and High-Speed USB OTG Controller

This chapter describes the high-speed universal serial bus (USB) host subsystem and the high-speed USB On-The-Go (OTG) controller of the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

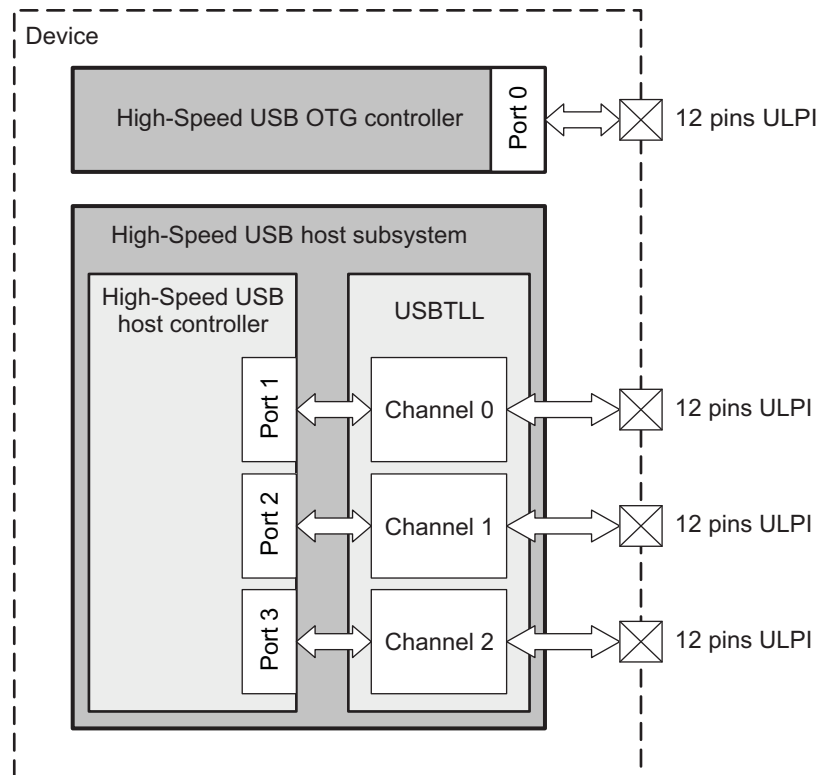

Topic	Page
22.1 High-Speed USB OTG Controller	3223
22.2 High-Speed USB Host Subsystem	3246

Overview

The device contains two USB modules:

- A High-Speed USB OTG Controller (see [Section 22.1, High-Speed USB OTG Controller](#))
- A High-Speed USB Host Subsystem (see [Section 22.2, High-Speed USB Host Subsystem](#))

Figure 22-1. USB Modules Overview

usb-035

22.1 High-Speed USB OTG Controller

NOTE: The High-Speed USB OTG Controller is an instantiation of the MUSBMHDCR from Mentor Graphics Corporation.

This document contains materials that are ©2003-2007 Mentor Graphics Corporation.

Mentor Graphics is a registered trademarks of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

22.1.1 High-Speed USB OTG Controller Overview

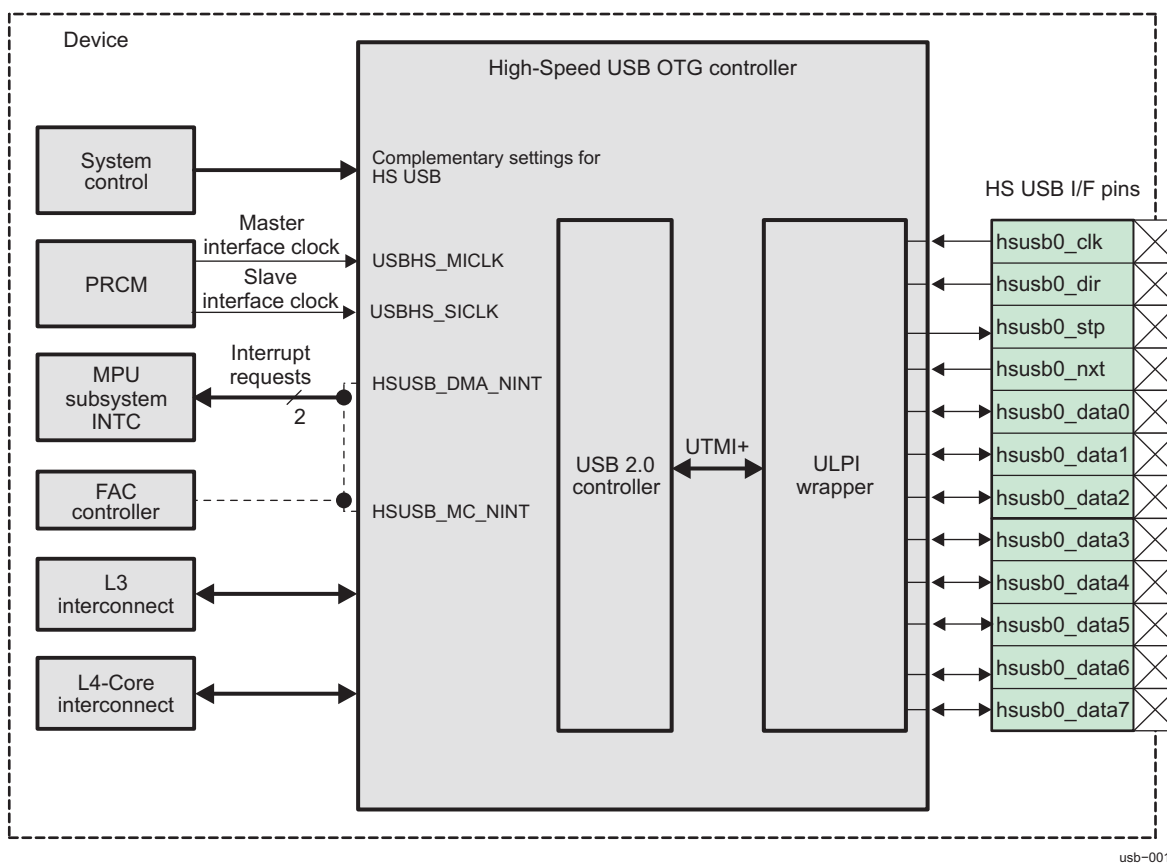

The High-Speed USB OTG dual-role-device (DRD) link controller supports the following modes:

- USB 2.0 peripheral (function controller) in high/full speed (480/12 Mbps, respectively)
- USB 2.0 host in high/full/low speed (480/12/1.5 Mbps respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 2.0 OTG DRD in high/full speed, with HNP and SRP support.

The high-speed USB controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode).

Figure 22-2 highlights the high-speed USB controller.

Figure 22-2. High-Speed USB Controller Highlight

usb-001

22.1.1.1 Main Features

The high-speed USB controller has the following features:

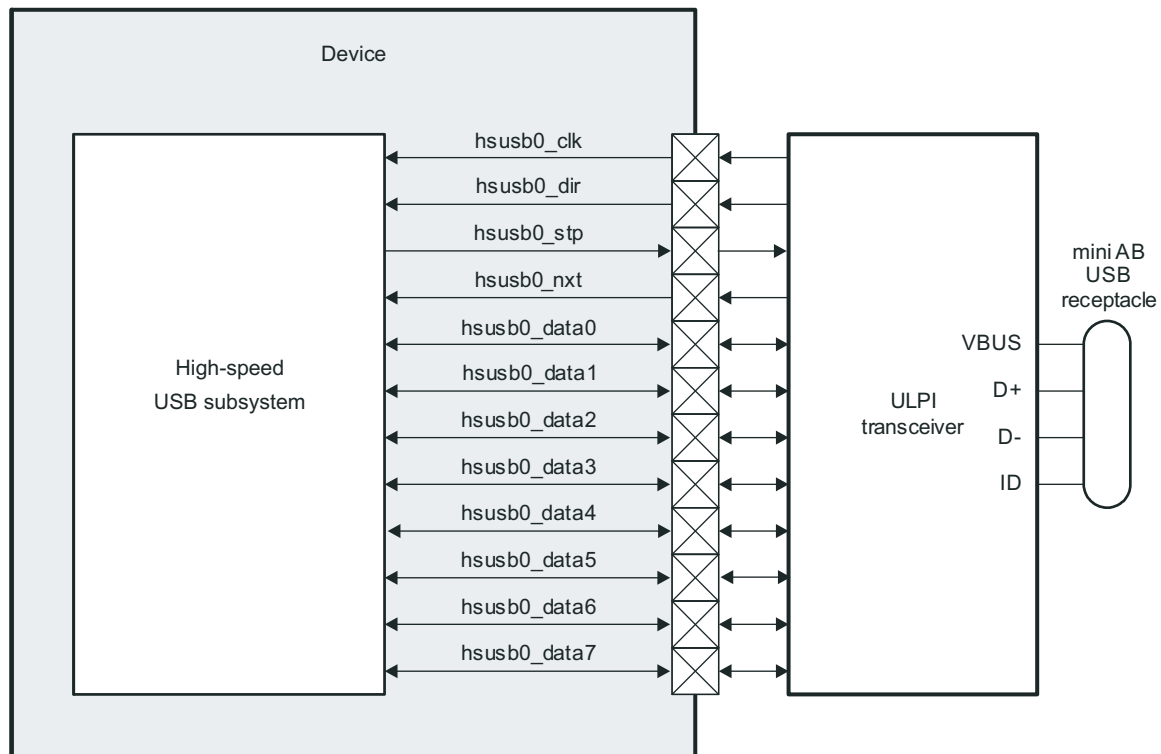

- Operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multipoint communications with other USB functions

- Complies with the USB 2.0 standard for high-speed (480 Mbps) functions and with the OTG supplement (Revision 1.0a)
- Includes all transfer types: Control, bulk, isochronous, interrupt
- Supports SRP and HNP
- Supports suspend/resume and remote wakeup
- Supports high-bandwidth isochronous and interrupt transfers
- Contains one PHY (physical layer) interface: ULPI interface (12/8-pin version)
- 15 transmit endpoints and 15 receive endpoints in addition to control endpoint 0
- Each endpoint has its own FIFO, with the following properties:
 - Implemented within a single, 16K-byte internal RAM
 - Can be dynamically sized by software
 - Can be configured to hold multiple packets (up to 8192 bytes per FIFO)
 - Can be accessed either by direct access or by DMA controller
- Software connect/disconnect option for peripheral
- Performs all transaction scheduling in hardware

22.1.2 High-Speed USB OTG Controller Environment

Figure 22-3 shows a typical application using the high-speed USB controller.

Figure 22-3. High-Speed USB Controller Typical Application System

usb-002

The high-speed USB controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode). A mini A-B external receptacle allows the connection of an external device.

The current implementation of ULPI includes a method for manual, software-controlled generation of PHY-side register accesses supporting the following features:

- Access to vendor-specific or optional PHY-side registers
- Carkit operation (including interrupt, PHY-side registers)
- Access to vendor ID, product ID, scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY clock (SDR mode); the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edge (DDR mode).

The TI high-speed USB controller supports only the 12-pin, 8-bit version ULPI interface.

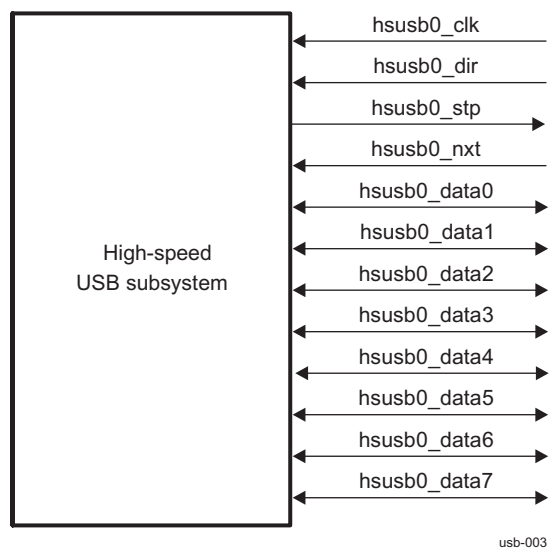

The 12-pin/8-bit data SDR ULPI interface is selected through the `USBOTG.OTG_INTERFSEL[1:0]` PHYSEL field and must be set to 0x1.

22.1.2.1 High-Speed USB Controller Functional Interfaces

22.1.2.1.1 Basic High-Speed USB Controller Pins

Figure 22-4 shows the high-speed USB controller functional interface.

Figure 22-4. High-Speed USB Controller Functional Interface Signals

22.1.2.1.2 High-Speed USB Controller Interface Description

Table 22-1 describes the I/O of the high-speed USB controller interface.

Table 22-1. Input/Output Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value
hsusb0_clk	I	60-MHz clock input from ULPI PHY	N/A
hsusb0_dir	I	Data direction control from ULPI PHY	N/A
hsusb0_stp	O	Stop signal to ULPI PHY	1
hsusb0_nxt	I	Next signal from ULPI PHY	N/A
hsusb0_data0	I/O	Bidirectional DATA0	N/A
hsusb0_data1	I/O	Bidirectional DATA1	N/A
hsusb0_data2	I/O	Bidirectional DATA2	N/A
hsusb0_data3	I/O	Bidirectional DATA3	N/A
hsusb0_data4	I/O	Bidirectional DATA4	N/A
hsusb0_data5	I/O	Bidirectional DATA5	N/A
hsusb0_data6	I/O	Bidirectional DATA6	N/A
hsusb0_data7	I/O	Bidirectional DATA7	N/A

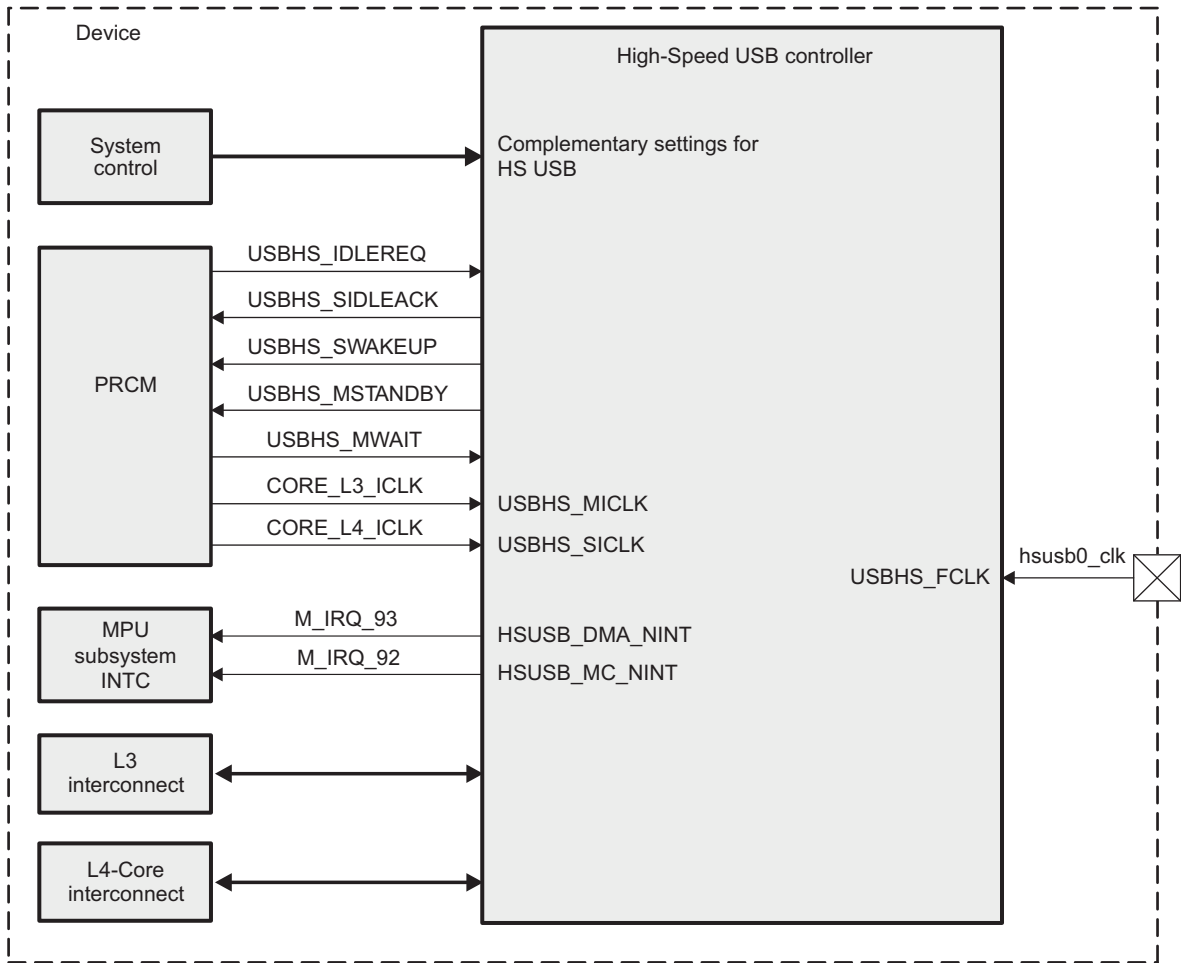

⁽¹⁾ I = Input; O = Output

22.1.3 High-Speed USB OTG Controller Integration

The high-speed USB controller is connected to L3 interconnect master (initiator) and slave (target) interfaces and L4-Core interconnect. The L3 interconnect generates data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Figure 22-5 highlights the high-speed USB controller integration in the device.

Figure 22-5. High-Speed USB Controller Integration

usb-004

22.1.3.1 Clocking, Reset, and Power-Management Scheme

22.1.3.1.1 Clocks

22.1.3.1.1.1 Module Clocks

Three clocks are provided to the high-speed USB controller, as shown in Table 22-2.

Table 22-2. USB Clocks

Attributes	Frequency	Name	Mapping	Comments
Functional clock	60 MHz	USBHS_FCLK	hsub0_clk	Source is external transceiver (ULPI)
Master Interface clock	Depending on PRCM register settings	USBHS_MICLK	CORE_L3_ICLK	Source is PRCM module

Table 22-2. USB Clocks (continued)

Attributes	Frequency	Name	Mapping	Comments
Slave Interface clock	Depending on PRCM register settings	USBHS_SICLK	CORE_L4_ICLK	Source is PRCM module

22.1.3.1.1.2 Master Interface Clock

The master interface clock USBHS_MICLK comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN1_CORE[4]:

0: Disabled
1: Enabled

and PRCM.CM_AUTOIDLE1_CORE[4] (enables/disables automatic control of the interface clock)-see [Table 22-3](#).

Table 22-3. High-Speed USB Interface Clock

PRCM.CM_AUTOIDLE1_CORE[4]	PRCM.CM_ICLKEN1_CORE[4]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

22.1.3.1.1.3 Functional Clock

The functional clock (60MHz), USBHS_FCLK, comes from the external ULPI transceiver through the hsub0_clk input pin.

22.1.3.1.2 Resets

The high-speed USB controller can be reset either by the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in the module.

22.1.3.1.2.1 Hardware Reset

The high-speed USB controller is attached to the CORE power domain: The CORE_RST signal resets the module (see [Chapter 3, Power, Reset, and Clock Management](#)). The hardware reset signal has a global reset action on the high-speed USB controller.

22.1.3.1.2.2 Software Reset

The high-speed USB controller has a software reset through the USBOTG.OTG_SYSCONFIG[1] SOFTRESET bit (0: Normal mode, 1: Module is reset).

This bit controls the software reset. Writing 1 to this bit resets the module. The bit value 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

22.1.3.1.3 Power-Management Scheme

22.1.3.1.3.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB functional clock (60 MHz), USBHS_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

22.1.3.1.3.2 System Power Management

Master Interface Power Management

The high-speed USB controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB controller has a MSTANDBY handshake mechanism with the PRCM module (see [Figure 22-5](#)).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field.

- Smart standby

The high-speed USB controller is configured in smart-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force standby

The high-speed USB controller is configured in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).

- When the high-speed USB controller operates as a host: The USBOTG.POWER[1] SUSPENDMODE bit is set to 1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. The USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit must be set to 1 to assert MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:
 - Remote wakeup causes a RESUME interrupt
 - Set the USBOTG.POWER[3] RESET bit to 1.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.

OR

 - Set the USBOTG.POWER[3] RESET bit to 1.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
- When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a SUSPEND interrupt is generated by the high-speed USB controller. The USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit must be set to 1 to enable the MSTANDBY signal. The high-speed USB controller then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the

following two cases:

- Set the USBOTG.POWER[2] RESUME bit to 1.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
- OR
- RESET interrupt is generated by the high-speed USB controller.
 - Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.

When MSTANDBY is deasserted as a consequence of the previous register access, the module waits for MWAIT deassertion before a DMA transfer is started.

- No standby

The high-speed USB controller is configured in no-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x1). The module never enters standby mode (that is, MSTANDBY is never asserted).

Table 22-4 describes the high-speed USB master interface power management modes.

Table 22-4. High-Speed USB Master Interface Power Management Modes

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE Field
Force-standby	0x0
No-standby	0x1
Smart-standby	0x2
Reserved	0x3

Slave Interface Power Management

The high-speed USB controller can be configured through the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Smart-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock USBHS_ICLK is disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
- L4 interface clock idle transitions:

Configured in smart-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from idle mode if the USBOTG.OTG_SYSCONFIG[2] ENABLEWAKEUP bit is set to 1 (wake-up capability enabled) and the PRCM register bit PRCM.PM_WKEN1_CORE[4] is also set to 1.

- Force-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock USBHS_ICLK is disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
- The L4 interface clock idle transitions:

Configured in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is

totally inhibited.

- No-Idle Mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock(s) USBHS_ICLK are disabled (PRCM register bit PRCM.CM_ICLKEN1_CORE[4] set to 0) or under automatic control (PRCM register bits PRCM.CM_ICLKEN1_CORE[4] and PRCM.CM_AUTOIDLE1_CORE[4] both set to 1)
- L4 interface clock idle transitions

Configured in no-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

Table 22-5 describes the high-speed USB slave interface power management modes.

Table 22-5. High-Speed USB Slave Interface Power Management Modes

Power Management Mode Requested by the PRCM	USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE Field
Force-idle	0x0
No-idle	0x1
Smart-idle	0x2
Reserved	0x3

NOTE: The high-speed USB controller standby status can be checked by the PRCM module register bit CM_IDLEST1_CORE[4].

- 0: High-Speed USB is active.
- 1: High-Speed USB is in standby mode.

The high-speed USB controller wake-up status can be checked by the PRCM module register bit PM_WKST1_CORE[4].

- Read 0: Wakeup has not occurred or was masked.
- Read 1: Wakeup has occurred.
- Write 0: Status bit unchanged.
- Write 1: Status bit is cleared to 0.

22.1.3.1.3.3 Local Power Management

The high-speed USB controller has local power management by internal clock gating features:

- Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

22.1.3.1.4 Power Domain

The high-speed USB controller is attached to the CORE power domain (see [Chapter 3, Power, Reset, and Clock Management](#)).

22.1.3.2 Hardware Requests

22.1.3.2.1 Interrupt Requests

Table 22-6 lists the interrupt lines that are driven out from the high-speed USB controller to the MPU subsystem INTC.

Table 22-6. High-Speed USB Interrupts

Name	Mapping	Comments
HS USB Controller Interrupt		
HSUSB_MC_NINT	M_IRQ_92	Destination is MPU subsystem interrupt controller
HS USB DMA Controller Interrupt		
HSUSB_DMA_NINT	M_IRQ_93	Destination is MPU subsystem interrupt controller

22.1.3.2.2 IDLE Handshake Protocol

The PRCM handles an IDLE handshake protocol for the high-speed USB controller. The IDLE handshake protocol allows the PRCM requiring the high-speed USB controller to enter idle mode. The high-speed USB controller acknowledges when it is ready.

22.1.3.2.3 MSTANDBY Handshake Protocol

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

22.1.3.2.4 Wake-Up Request

The high-speed USB controller generates a wake-up request signal (UBSHS_SWAKEUP) to the PRCM module.

22.1.4 High-Speed USB OTG Controller Functional Description

22.1.4.1 Inventra™ MUSBMHDC

The core functionality of the module is provided by a third-party IP, the Inventra MUSBMHDC from Mentor Graphics Corporation.

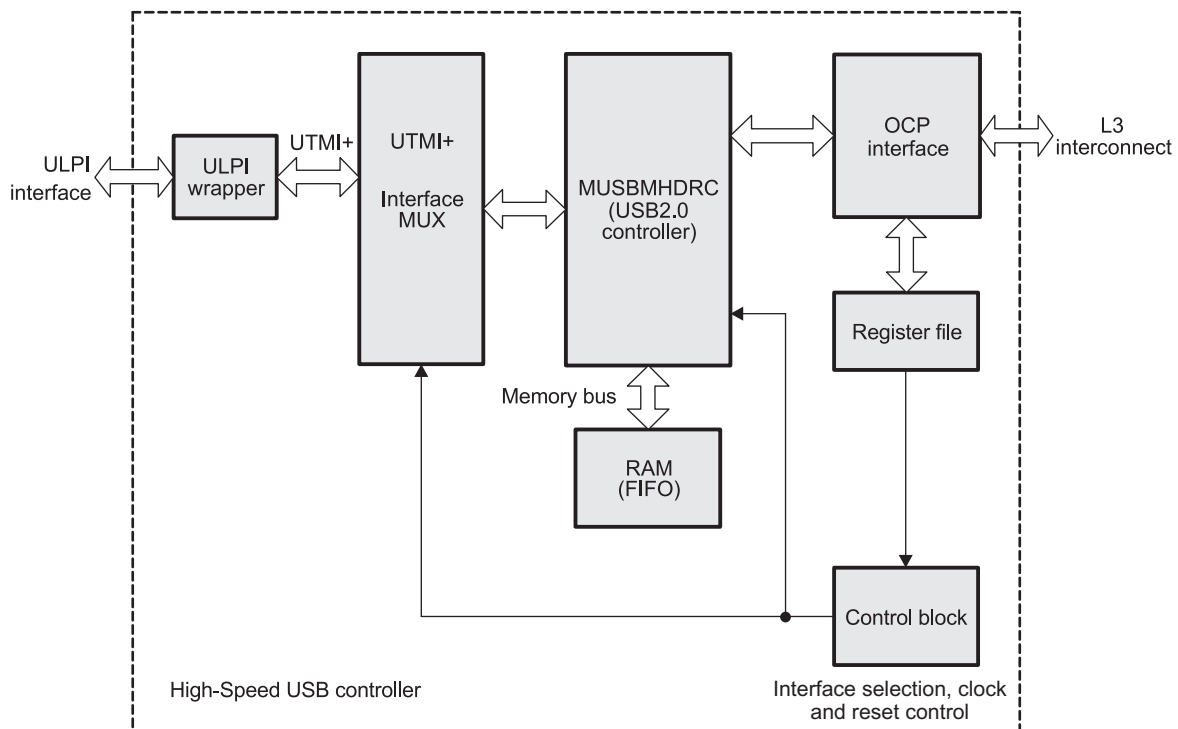

The high-speed USB controller is basically the appropriate adaptation/integration of this IP to comply with TI requirements.

The high-speed USB controller includes the following:

- MUSBMHDC (USB 2.0 controller)
- Master and slave bridges for conversion AHB to L3 interconnect and L3 interconnect to AHB
- Two memories (total of 16Kbytes; available for various endpoints)
- Reset and clock generation

Figure 22-6 shows the high-speed USB controller.

Figure 22-6. High-Speed USB Controller

usb-005

22.1.4.2 Configuration

The Mentor Graphics IP RTL MUSBMHDRC can be configured to generate some customized hardware. Those options are all hard-wired and cannot be reprogrammed in the case of the TI High-Speed USB controller.

The following options are selected:

- 8-bit internal data path processing width (mandated by the use of ULPI)
- 32-bit vcontrol/vstatus support
- External charge pump: Hacked
- Software connect/disconnect supported
- Little-endian and big-endian byte ordering
- Eight DMA channels (with internal DMA initiator implemented)
- Dynamic FIFO sizing enabled
- 16K bytes RAM buffer
- 15 IN/OUT endpoints in addition to control endpoint 0
- IN/OUT bulk packet splitting/combining enabled
- High-bandwidth IN/OUT isochronous support enabled (see *Universal Serial Bus Specification Revision 2.0*)

22.1.4.3 Basic Operation

This section provides an overview of the module basic operation.

To implement the most time-critical functions in hardware, the module provides all of the encoding, decoding, and checking required to send and receive USB packets-interrupting the MPU only when endpoint data is successfully transferred. Generally, the following steps are performed:

22.1.4.3.1 Module Initialization

First, the firmware must do the overall initialization of the module by configuring the interrupts, the DMA controller, and the individual endpoints.

The specific items of a configuration are for each endpoint:

- Direction TX/RX
- Speed: High/full/low
- Special host settings when used in host mode (function address/hub parameters, etc.)
- Transaction protocol: Control/isochronous/bulk/interrupt
- Maximum packet size, that can be transferred through the endpoint
- Whether DMA is required (DMA enable)
- DMA mode
- Start address of the endpoint FIFO within the RAM block
- Maximum packet size allowed
- Whether double-buffering is required. This and the previous option define the amount of space that must be allocated to the FIFO. In the case of double-buffering, the FIFO size is doubled; therefore, the maximum supported size is 8196 bytes for the endpoint FIFOs.

NOTE: On the system level, it must be ensured that the reset and the interface are selected before the 60-MHz functional clock (USBHS_FCLK) is applied to the module. Correct functionality is not ensured if either a reset deassertion or a change in the interface selection occurs when the functional clock USBHS_FCLK is already running.

22.1.4.3.1.1 MSTANDBY Deassertion

MSTANDBY is asserted during reset and continues to be 1 after reset. The high-speed USB controller does not perform master interface transactions until this signal is deasserted. Firmware must follow these steps to begin normal operations on the master interface bus:

- Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit.
- Put the high-speed USB controller into no-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x1) and no-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDLEMODE field = 0x1).

Even though ENABLEFORCE is 0, MSTANDBY remains asserted until the high-speed USB controller core is out of idle state.

22.1.4.3.2 Transaction Handling

Depending on whether the module is in the host or peripheral mode, an RX endpoint is assigned to IN or OUT transactions, respectively. Similarly, a TX endpoint is used for IN transactions in the peripheral mode and for OUT transactions in the host mode. When a transaction is complete, the appropriate endpoint interrupt is generated (if enabled).

When a transaction is handled through an RX endpoint, the received packet is placed in the RX FIFO, and the appropriate RX endpoint interrupt is generated. The packet can then be unloaded from the FIFO either manually (that is, by the MPU) or by the DMA. Although an RX endpoint is always active for a peripheral, in host mode the transaction must first be initiated by setting the appropriate request flag (REQPKT). This indicates to the transaction scheduler that there is an active transaction on this endpoint, which requires an IN token to be sent to the target function.

When a transaction is handled through a TX endpoint, the packet to send is loaded into the TX FIFO either manually (that is, by the MPU) or by the DMA. The transaction then must be initiated by setting the appropriate ready flag (TXPKTRDY) to indicate the availability of the new packet. When the packet is successfully sent (scheduled according to the protocol rules), the appropriate TX interrupt is generated.

22.1.4.4 Optional Features

This section gives a quick overview of the optional features that are available, depending on the endpoint configuration.

22.1.4.4.1 Double Packet Buffering

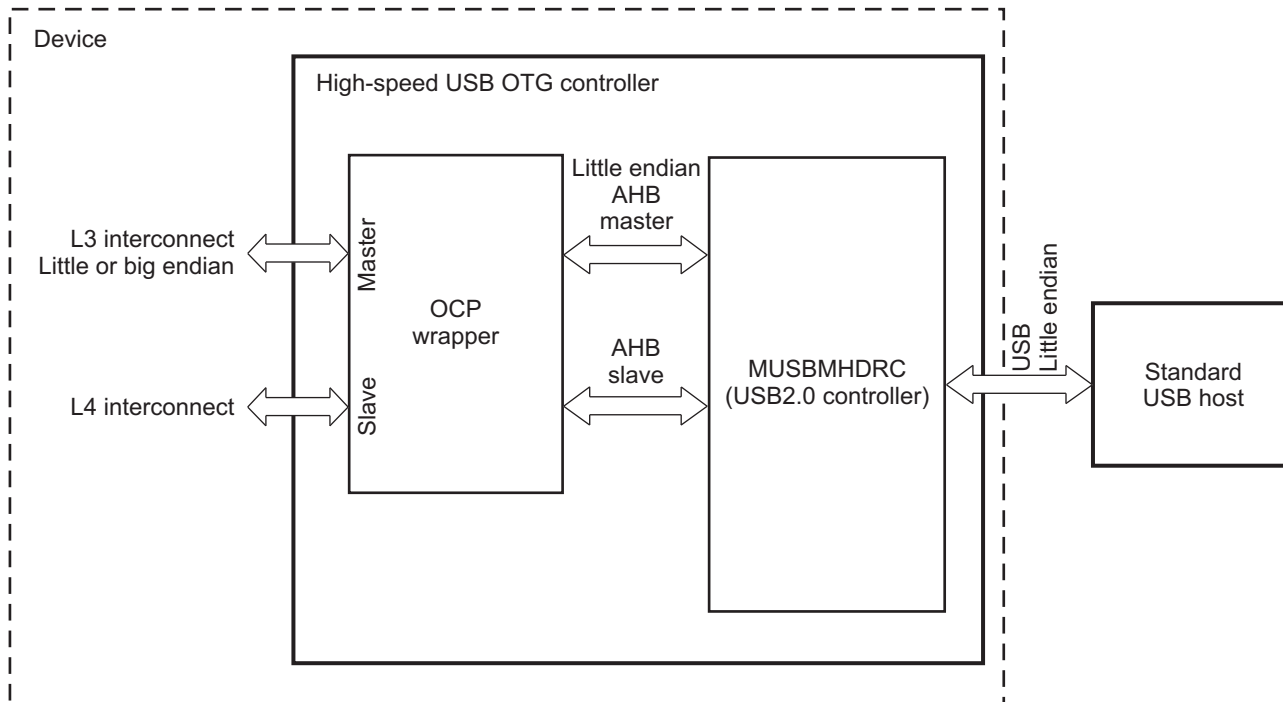

When double packet buffering is enabled (by setting the MSB of the FIFOSZ register two data packets can be stored in the FIFO. This option can be set for both the TX and RX endpoints in both the peripheral and host mode. For a TX endpoint, double-buffering means that up to two packets can be loaded into the FIFO awaiting transmission; for an RX endpoint, one packet can be received while another is being read. Double packet buffering is especially advisable for isochronous transactions to avoid underrun or overrun errors.

The high-speed USB controller provides dynamic FIFO sizing with an overall RAM size of 16K bytes, which can then be allocated to the different endpoints when the module is initialized. The maximum size of an endpoint FIFO is 4096 bytes for single packet buffering and 8192 bytes for double packet buffering. The firmware must ensure that a block of RAM is properly assigned to all TX and RX endpoints, considering the total RAM size and the maximum packet size set for the endpoint.

22.1.4.4.2 High-Speed USB OTG Support for Big Endian

In the example in [Figure 22-7](#), the high-speed USB OTG controller module is configured as a USB device and is connected to a standard USB host. The two interconnect interfaces of the high-speed USB OTG controller connect it to the system bus. The register read/write is performed through the interconnect slave interface (control path). The data transfer to/from system memory takes place through the interconnect master interface (data path).

The data transfer on the USB is always in little-endian mode, but on interconnect it can be in little- or big-endian mode, as shown in [Figure 22-7](#).

Figure 22-7. High-Speed USB OTG Controller Endianness

usb-036

Big-endian support in the high-speed USB OTG controller may or may not require byte-swapping in the data path. Byte-swapping is performed based on the unit size of data. For example, if multiple bytes are packed into one 32-bit word, these bytes must be swapped in a big-endian interconnect. On the other hand, if the data is only a 32-bit word (for example, a 32-bit descriptor pointer in a memory buffer), the bytes in the word must not be swapped in big-endian mode.

In the high-speed USB OTG controller, the unit size of descriptors/descriptor pointers is 32 bits and that of the USB data is 8 bits. Four 8-bit USB data are packed to form a 32-bit word. This 32-bit data requires byte-swapping, whereas the descriptors/descriptor pointers do not require the same.

NOTE: Byte-swapping is not required in the control path (slave interface).

The OCP master interface (a submodule within the OCP wrapper) supports big-endian conversion by setting the OTG_BIGENDIAN[0] BIG_ENDIAN bit to 0x1.

For interconnect write transactions, the data word is swapped as shown in [Table 22-7](#) before its output on the interconnect master interface. In case of an interconnect read transaction, the received data is swapped before its output on the AHB master interface of the MUSBMHDC core. The OCP MByteEn is swapped before the command is issued on the OCP master interface. The OCP MAddr is always aligned to the interconnect data size (32 bits). Therefore, the OCP MAddr is always word-aligned.

Table 22-7. Interconnect Data and MByteEn in Little- and Big-Endian Modes

Unit Size of Data	AHB Size (of Packed/Nonpacked Data)	AHB Start Address Offset (Always in Little-Endian Mode)	OCP MByteEn in Little-Endian Mode	OCP MByteEn in Big-Endian Mode	OCP Data in Little-Endian Mode	OCP Data in Big-Endian Mode
Byte	Byte	0	0001	1000	xxxb0	b0xxx
Byte	Byte	1	0010	0100	xxb0x	xb0xx
Byte	Byte	2	0100	0010	xb0xx	xxb0x
Byte	Byte	3	1000	0001	b0xxx	xxx b0
Byte	Half-word	0	0011	1100	xxb1b0	b0b1xx

Table 22-7. Interconnect Data and MByteEn in Little- and Big-Endian Modes (continued)

Unit Size of Data	AHB Size (of Packed/Nonpacked Data)	AHB Start Address Offset (Always in Little-Endian Mode)	OCP MByteEn in Little-Endian Mode	OCP MByteEn in Big-Endian Mode	OCP Data in Little-Endian Mode	OCP Data in Big-Endian Mode
Byte	Half-word	2	1100	0011	b1b0xx	xxb0b1
Byte	Word	0	1111	1111	b3b2b1b0	b0b1b2b3
Half-word	Half-word ⁽¹⁾	0	0011	1100	xxb1b0	b1b0xx
Half-word	Half-word ⁽¹⁾	2	1100	0011	b1b0xx	xxb1b0
Half-word	Word ⁽¹⁾	0	1111	1111	b3b2b1b0	b1b0b3b2
Word	Word ⁽²⁾	0	1111	1111	b3b2b1b0	b3b2b1b0

⁽¹⁾ Not a likely scenario for high-speed USB OTG controller

⁽²⁾ Corresponds to descriptor and descriptor pointer. No bytes are packed to form a word; therefore, no byte-swapping is done in this case.

22.1.4.4.3 DMA

The high-speed USB controller has an internal DMA controller for efficient loading/unloading of the endpoint FIFOs.

If the DMA is enabled for a TX endpoint, a DMA transfer occurs whenever the endpoint can accept another packet in its FIFO (that is, the DMA controller loads the packets into the FIFO without processor intervention).

If the DMA is enabled for an RX endpoint, a DMA transfer occurs whenever the endpoint has a packet in its FIFO (that is, the DMA CONTROLLER unloads the packets from the FIFO without processor intervention).

The high-speed USB controller supports two DMA request modes, which also affects the generation of endpoint interrupts.

- DMA request mode 0 is especially advisable for isochronous transfers but can also be used for bulk and interrupt transfers.
- DMA request mode 1 is mainly valuable for bulk transfers, where typically a large block of data is split into a series of packets of the maximum size.

22.1.4.4.3.1 DMA Request Mode 0

For RX endpoints, the DMA transfer is initiated when a data packet is available in the endpoint FIFO. The appropriate endpoint interrupt is also generated after the packets are received.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is also generated to prompt the loading of the packets.

22.1.4.4.3.2 DMA Request Mode 1

For RX endpoints the DMA transfer is initiated only when the received packet is the maximum packet size (as set in the RXMAXP register for the corresponding endpoint). The appropriate endpoint interrupt is generated only when the received packet is a short packet (that is, one less than the maximum packet size); otherwise, it is suppressed.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is suppressed.

22.1.4.4.3.3 Internal DMA Controller

The high-speed USB controller has an internal DMA controller to perform DMA transfers acting as host on the L3 interconnect. The DMA controller has eight channels, which can be independently programmed based on the following configuration options:

- DMA enable

- Direction (DMA write/DMA read)
- DMA mode (transfer one or more packets)
- Interrupt enable
- Endpoint number
- L3 interconnect memory address (32 bits)
- Byte count

The DMA controller can issue single accesses (8-, 16-, or 32-bit) and also bursts (4 x 32-bit, 8 x 32-bit, or 16 x 32-bit) on the L3 interconnect. The start address provided to the DMA controller must be 32-bit aligned.

22.1.4.5 Automatic Packet Splitting/Combining for Bulk Transfers

The high-speed USB controller offers the facility for bulk endpoints to store larger amounts of data in their FIFOs than can be transferred in a single USB operation. In other words, the module includes a configuration option that, if selected, allows larger data packets to be written to bulk TX endpoints, which are then split into packets of an appropriate size for transfer across the USB. A similar option exists for bulk RX endpoints, which, if selected, causes the module to combine the packet received across the USB into larger data packets before being read by the application software.

The firmware can enable these options by setting the corresponding bits (MPRXE and MPTXE) in the CONFIGDATA register. The necessary packet size information contains the payload size for one transaction and a multiplier defining the maximum number of USB packets. The payload is required to be either 8, 16, 32, 64, or (in case of high-speed transfers) 512 bytes; the multiplier can be any value up to 32.

22.1.4.6 High-Bandwidth Isochronous Endpoints

In the high-speed mode, isochronous endpoints can transfer up to three USB packets in any microframe with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per microframe (see *Universal Serial Bus Specification Revision 2.0*).

For TX endpoints, the high-speed USB controller supports this by allowing loading data packets of up to 3072 bytes (that is, 3 x 1024 bytes) into the associated endpoint FIFO, which is then automatically split into USB packets of the maximum payload, or smaller to be transmitted in one microframe.

For RX endpoints, the module automatically combines all the USB packets received during a microframe into a single packet of up to 3072 bytes (that is, 3 x 1024 bytes) within the RX FIFO.

The number of USB packets transferred per microframe and the maximum payload in each packet is defined through the appropriate registers (RXMAXP and TXMAXP).

22.1.5 High-Speed USB OTG Controller Basic Programming Model

This section describes only the TI-specific programming model details.

22.1.5.1 High-Speed USB Controller Interface Selection

The TI High-Speed USB controller supports only the 12-pin/8-bit data version ULPI interface (see [Table 22-16](#)).

The 8-pin, 4-bit version ULPI interface and 8-bit UTMI+ Level 3 interface are not supported.

The 12-pin/8-bit data SDR ULPI interface is selected through the USBOTG.OTG_INTERFSEL[1:0] PHYSEL field set to 0x1.

22.1.5.2 Enable Simulation Acceleration Features

The USBOTG.OTG_SIMENABLE register is dedicated solely for simulation (see [Table 22-18](#)) and is used to reduce timer length and, hence, the time taken for the test bench to run.

This special mode can be active only during simulation and must be disabled for normal operation. The firmware must keep TM1 inactive (reset value) during normal operation. An accidental write to this register can cause a malfunction.

22.1.5.3 Enabling MSTANDBY in Force-Standby Mode

The USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit controls MSTANDBY behavior in force-standby mode only (see [Table 22-20](#)). In this mode, only when the internal core is idle (the module has no activity; that is, the USB is in suspend state) and when 1 is written to this bit, MSTANDBY goes high. Similarly, when ENABLEFORCE is 0 and the internal core is also in a non-idle state, MSTANDBY is deasserted. This bit does not influence MSTANDBY behavior in all other modes, such as no-standby and smart-standby.

22.1.5.4 Power Management Basic Programming Model

This section describes the settings for optimal High-Speed USB controller power management, depending on the use of this module in the application.

Two registers are involved in power management: USBOTG.OTG_SYSCONFIG and USBOTG.OTG_FORCESTDBY.

On reset, the high-speed USB controller has the following configuration:

- Master interface power management is in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is disabled (USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit = 0).
- MSTANDBY signal assertion is enabled (USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit = 1).

22.1.5.4.1 High-Speed USB Controller Not Used for Application

In this scenario, the high-speed USB controller is not used by the system software. Default settings must be changed to reduce power consumption. Enabling the internal clock autogating feature cuts off the module internal interface clock as soon as it is no longer required. This is done by setting the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1.

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

- Master interface power management is in force-standby mode (USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field = 0x0).
- Slave interface power management is in force-idle mode (USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field = 0x0).
- Internal clock autogating feature is enabled (USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit = 1).
- MSTANDBY signal assertion enabled (USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit = 1)

22.1.5.4.2 High-Speed USB Controller in Host Mode

When used as a host, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby and smart-idle modes.
2. Set the USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field to 0x2, the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that internal clock

autogating is not enabled while programming smart-idle mode.

3. Set the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

NOTE: The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

22.1.5.4.3 High-Speed USB Controller in Peripheral Mode

When used as a peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field to 0x2, the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 0 to program the smart-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming the smart-idle mode..
3. Set the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

NOTE: The internal clock autogating feature and smart-idle mode must not be programmed simultaneously.

22.1.5.4.4 High-Speed USB Controller in Host/Peripheral Mode

When used as a host/peripheral, the high-speed USB controller must be programmed as follows:

- Master interface power management in smart-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion disabled

See [Section 22.1.5.4.2](#) and [Section 22.1.5.4.3](#) for the programming sequence.

As an application required to disable the master interface, the high-speed USB controller can also be programmed as follows:

- Master interface power management in force-standby mode
- Slave interface power management in smart-idle mode
- Internal clock autogating feature enabled
- MSTANDBY signal assertion enabled

The programming sequence must be as follows:

1. Write 0 to the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to disable the MSTANDBY assertion before programming to smart-standby mode.
2. Set the USBOTG.OTG_SYSCONFIG[13:12] MIDDLEMODE field to 0x0, the USBOTG.OTG_SYSCONFIG[4:3] SIDLEMODE field to 0x2, and the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 0 to program the force-standby and smart-idle modes. Ensure that the internal clock autogating is not enabled while programming smart-idle mode.
3. Set the USBOTG.OTG_FORCESTDBY[0] ENABLEFORCE bit to 1 to enable the MSTANDBY assertion before enabling internal clock autogating feature.
4. Set the USBOTG.OTG_SYSCONFIG[0] AUTOIDLE bit to 1 to cut off the internal clocks to save power.

NOTE: The internal clock the autogating feature and smart-idle mode must not be programmed simultaneously.

22.1.6 High-Speed USB OTG Controller Register Manual

As this chapter describes only the TI-specific details, this section presents only the TI-specific registers of the high-speed USB controller.

Table 22-8 lists the base address and address space for the high-speed USB controller.

Table 22-8. High-Speed USB Controller Instance Summary

Module Name	Base Address	Size
USBHS	0x480A B000	4KB

CAUTION

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

22.2 High-Speed USB Host Subsystem

NOTE: Copyright ©2004,2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

22.2.1 High-Speed USB Host Subsystem Overview

The high-speed universal serial bus (USB) host subsystem is composed of the high-speed multiport USB host controller and the USBTLL module.

The USB controller is a high-speed multiport USB2.0 host controller. It contains two independent, 3-port host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*, is in charge of high-speed traffic (480M bit/s), over the ULPI/UTMI interface
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*, is in charge of full-speed/low-speed traffic (12/1.5M bit/s, respectively), over a serial interface

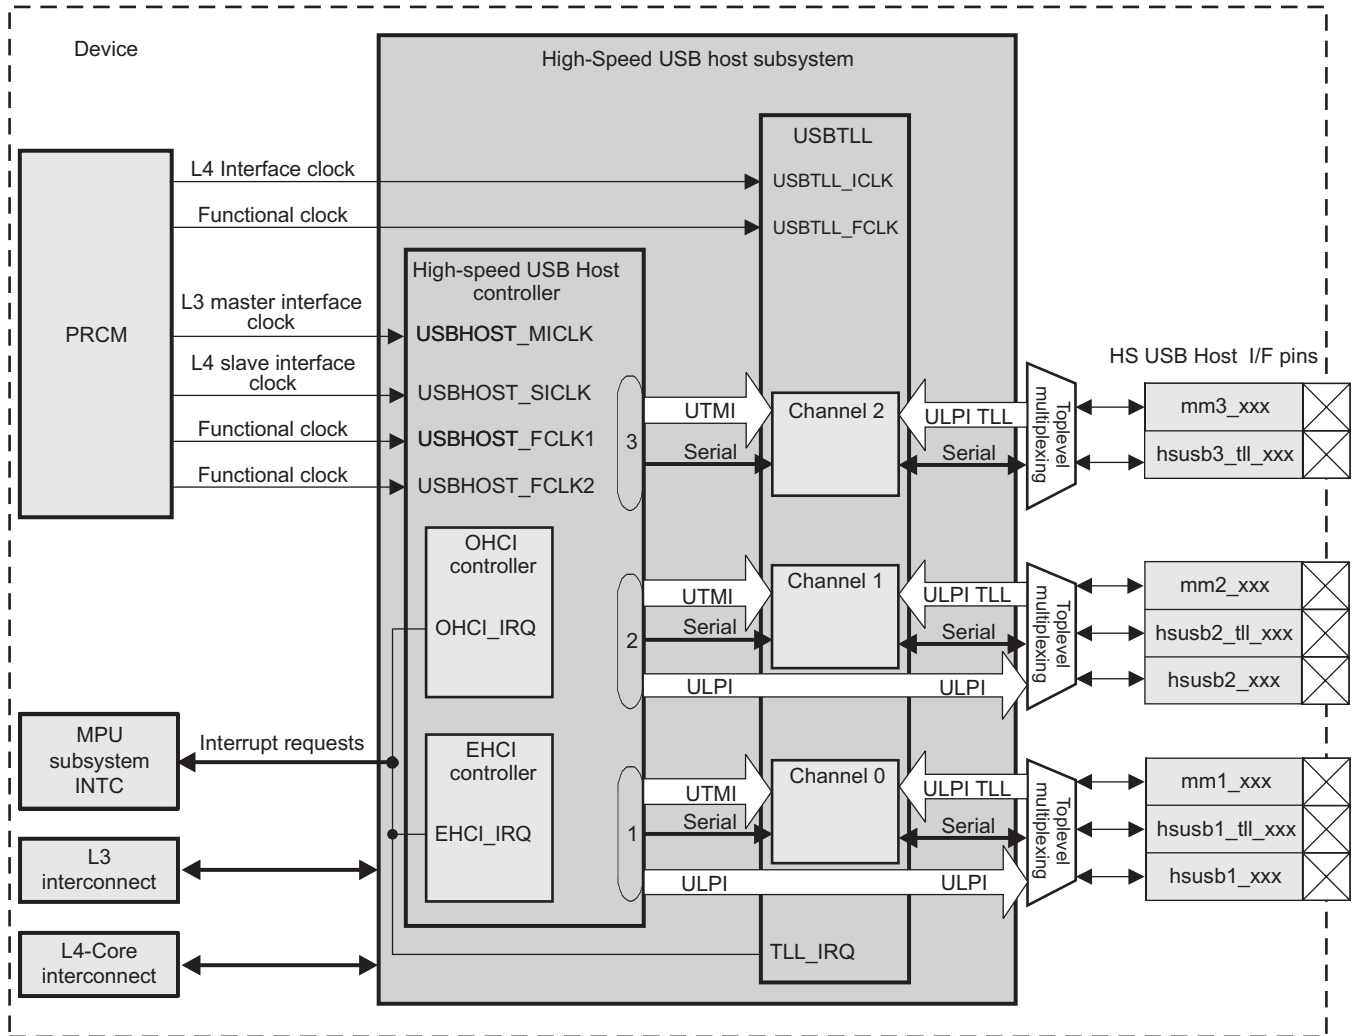

Each of the three device external ports is owned by exactly one and only one of the controllers at any time.

The USBTLL module is a high-speed USB UTMI low-pin interface (ULPI) transceiverless link logic (TLL) adapter. It implements a TLL compatible with a number of USB standard interface protocols. It consists of three channels, defined as independent USB path through the TLL module, which always converts the UTMI+ PHY interface protocol coming from the high-speed USB host controller.

Each USB port (1, 2, and 3) can connect either to an external-to-device chip USB transceiver or directly using a transceiverless link to an external integrated circuit (IC) supporting the same TLL protocol.

[Figure 22-8](#) highlights the high-speed USB host subsystem.

Figure 22-8. High-Speed USB Host Subsystem Highlight

usb-007

22.2.1.1 Main Features

The high-speed USB host subsystem includes the following features:

- Multiport high-speed USB host controller:
 - Complies with the USB 2.0 standard for high-speed (480 Mbps) functions
 - USB 2.0 low-speed (1.5M bit/s), full-speed (12M bit/s), and high-speed (480M bit/s) operations
 - Three downstream ports (3-port root hub)
 - Complies with EHCI (high-speed host controller)
 - Complies with OHCI (low-speed/full-speed host controller)
 - Supports suspend/resume and remote wakeup
 - Interface with USBTLL port A on all ports (UTMI+)
 - 8-bit datapath
 - 60-MHz synchronous (on-chip) interface
 - Interface with ULPI PHYs (transceivers) on all ports (only two mapped)
 - 12-pin/8-bit data single data rate (SDR) mode
 - 60-MHz clock input, provided by the host not the PHY (see TLL module below)

CAUTION

The HS USB host subsystem can only support the external charge pump of PHY (no support of internal charge pump for ULPI PHY)

- Hardware-driven save-and-restore of the suspended host hardware context
- Two interrupt lines
- USBTLL module
 - Three channels
 - Three ports (A, C, and D) by channel
 - Port A: PHY-side UTMI+ port. Connects to the local link controller. The UTMI "local" port is used in all configurations, (that is, the entire channel can be seen as a protocol converted from that port to one of the other, "remote" ports).
 - Compliant with UTMI+ (USB 2.0 Transceiver Macrocell Interface) version 1.0
 - 8-data-bit, 60-MHz UTMI (HS/FS/LS-capable)
 - UTMI+ Level 3 extensions
 - Vcontrol/Vstatus (from UTMI)
 - Serial FS/LS "6-pin" mode
 - Port C: PHY-side ULPI port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
 - SDR and dual data rate (DDR) ULPI capable (resp 8/4-bit data width modes)
 - Supports optional 6-pin/3-pin serial modes
 - Port D: Serial multimode port. Connects to either a serial link controller (TLL modes) or a serial PHY (PHY interface modes).
 - Supports 6-pin unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
 - All modes are supported for TLL or PHY interface configuration.
 - Supports sideband signals (pullup/down control, speed/suspend enable, etc)
 - An interrupt line
- USB port signal pins interface supporting:
 - External USB transceivers
 - ULPI interface: 12-pin/8-bit data SDR version; ULPI clock provided by the device
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
 - TLL mode
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode, (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode) and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Table 22-24. USB Connectivity Modes

USB Connectivity Modes	Port 1	Port 2	Port 3
ULPI interface	√	√	
Serial 6-pin transceiver interfaces	√	√	√
ULPI TLL interfaces	√	√	√
Serial 6-pin TLL interfaces	√	√	√

NOTE: Only FS/LS USB transceivers can be connected to port 3; HS ULPI transceivers are not supported on port 3.

WARNING

The three channels when in ULPI mode are always ULPI clock providers, an input clock is not accepted.

22.2.2 High-Speed USB Host Subsystem Environment

The high-speed USB host controller provides two kinds of interfaces for connection:

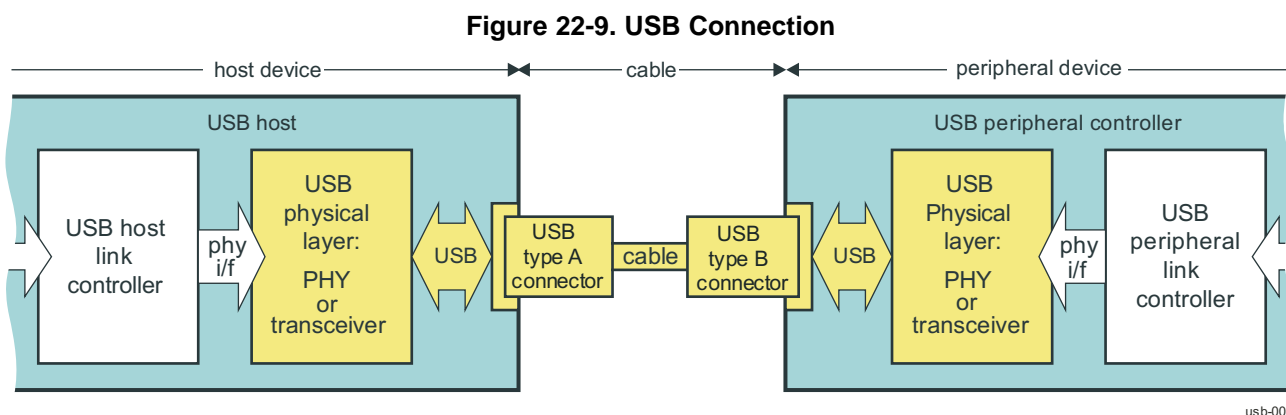

- ULPI interfaces for high-speed data transactions (up to 480M bit/s)
- Serial interfaces (with the use of the USBTLL module) for full- and low-speed data transactions (up to 12M bit/s)

The high-speed USB host controller connects to either controllers (TLL modes) and/or transceivers. It supports the following configurations with the serial interfaces and ULPI interfaces:

- External USB transceiver configurations
 - ULPI interface: 12-pin/8-bit data SDR version
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode) and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL configurations
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

22.2.2.1 Standard USB Implementation: Transceiver Connection

From a logical point of view, a point-to-point USB connection is composed of several blocks, organized in protocol layers, and shown in [Figure 22-9](#).

The host system (USB master) and the peripheral system (USB slave) connected through the USB cable include a link or controller (link layer) and a PHY or transceiver (physical layer). Each system talks to its own controller, which talks to its own transceiver, which is connected to the opposite side (transceiver) through an assembly of connectors, receptacles, and cable.

22.2.2.2 TLL Connection

The TLL feature enables connection of the high-speed USB host subsystem to an external, onboard USB peripheral controller, without using USB transceivers or associated circuitry. When TLL is used, the following components are removed:

- Both USB transceivers
- The series resistors
- Pullup and pulldown resistors
- VBUS switching components
- USB connectors and cables, typically used between a USB host controller and the downstream USB peripheral controller

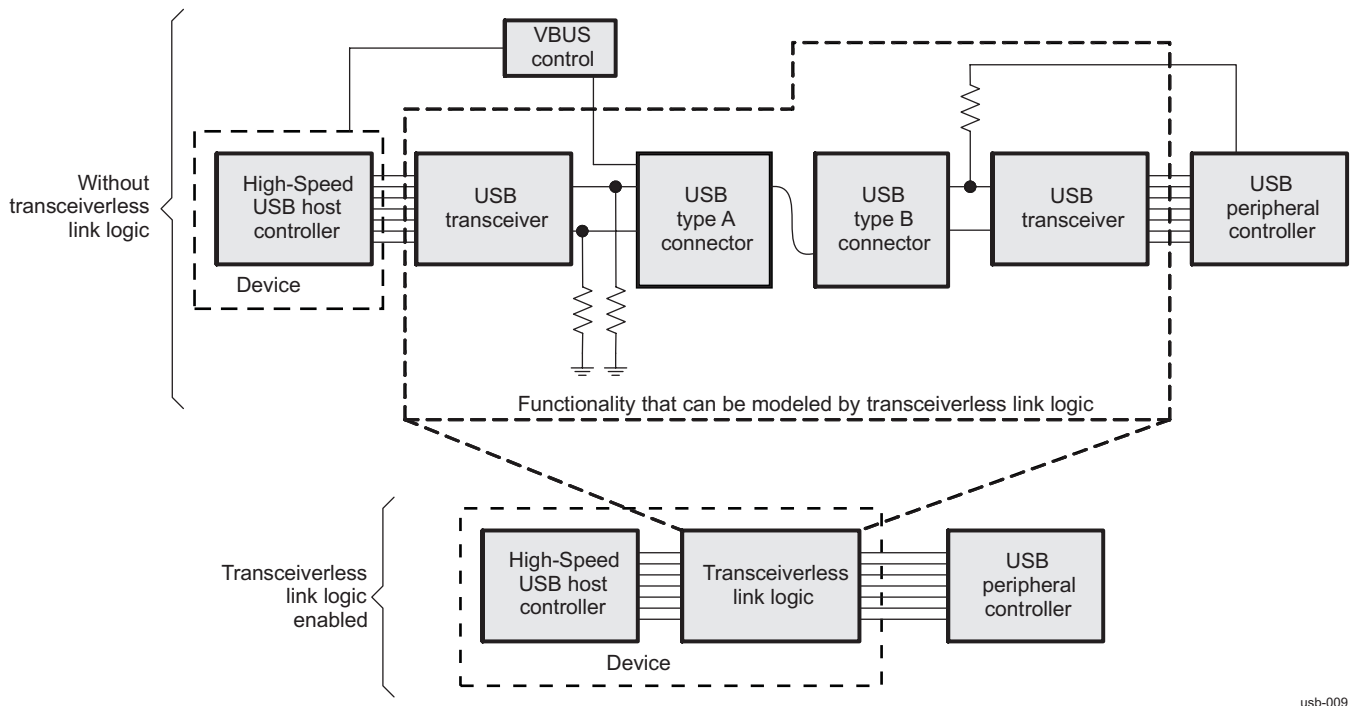

The TLL signaling system is not suitable for use across a cable. It is intended only for use when the device is used with an external USB integrated circuit (IC) that is on the same board.

When using the TLL, signals of the external USB IC pins, which typically connect to a USB transceiver, instead directly connect to the device pins. Signaling on these pins use CMOS levels. TLL logic can be used with external devices that support ULPI TLL interface and serial 6-pin TLL interface connectivity.

The TLL function in the device interprets the transmit control signals from the external USB IC and similar signals from the device USB host controller, and computes the equivalent USB differential-pair state. The computed differential-pair state is interpreted and the appropriate transceiver output signals are provided to the external USB IC and to the device USB host controller.

Figure 22-10 shows the device and how TLL can be compared to a typical USB implementation. The top portion of Figure 22-10 shows the a transceiver-based solution, and the bottom portion shows a transceiverless solution using TLL.

Figure 22-10. High-Speed USB Host Controller Connection-With and Without TLL

usb-009

NOTE: The USB bus lines (D+/D-) no longer appear in subsequent figures: They are emulated by the TLL.

22.2.2.3 ULPI Interfaces

The high-speed USB host subsystem supports the following configurations with the ULPI interfaces:

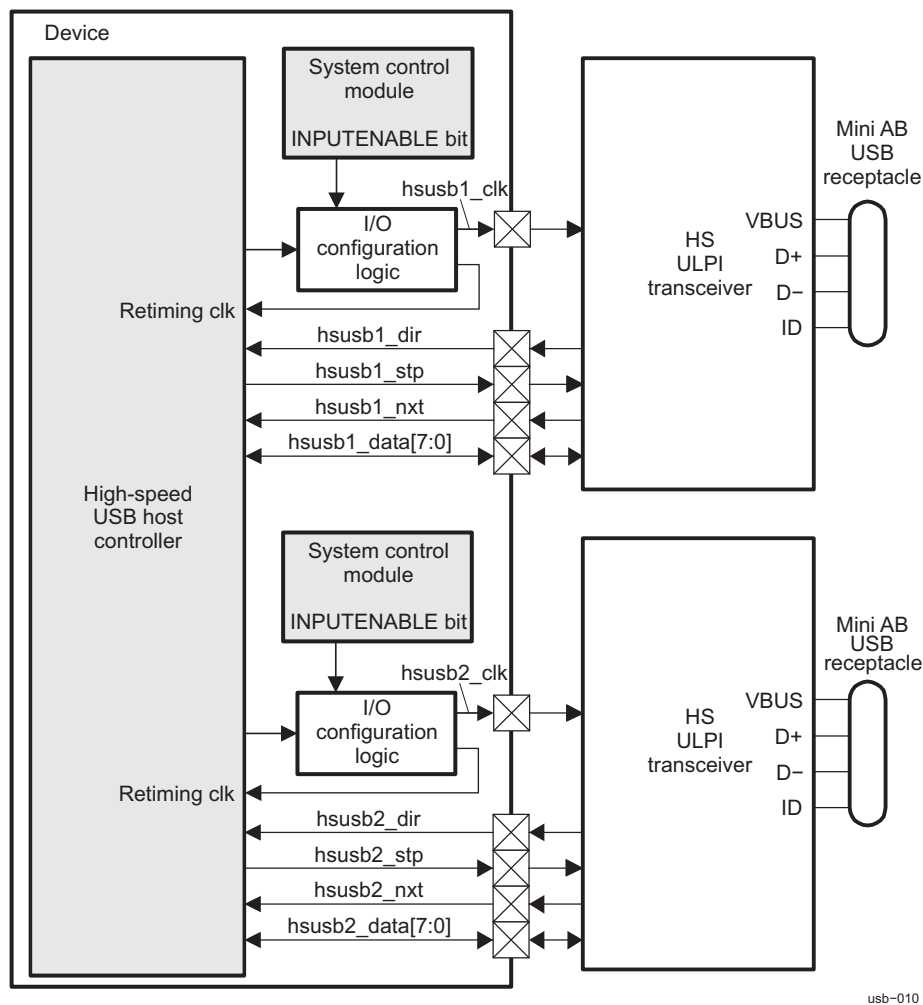

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data SDR version
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions

The high-speed USB host subsystem supports USB ports, which use the ULPI interface mode to connect to an off-chip high-speed ULPI transceiver (12-pin/8-bit data SDR mode) for high- and full-speed data transactions (up to 480M bit/s). Using the ULPI interfaces in 12-pin/8-bit data version, the device and the transceiver achieve the USB function. A mini A-B external receptacle allows the connection of an external device.

The device supports TLL logic interfaces on its ports in the ULPI TLL interface mode. TLL modes enable glueless interconnect to another USB device port without a costly transceiver.

Figure 22-11 and Figure 22-12 show typical applications using the high-speed USB host subsystem with the ULPI, and the ULPI TLL, respectively.

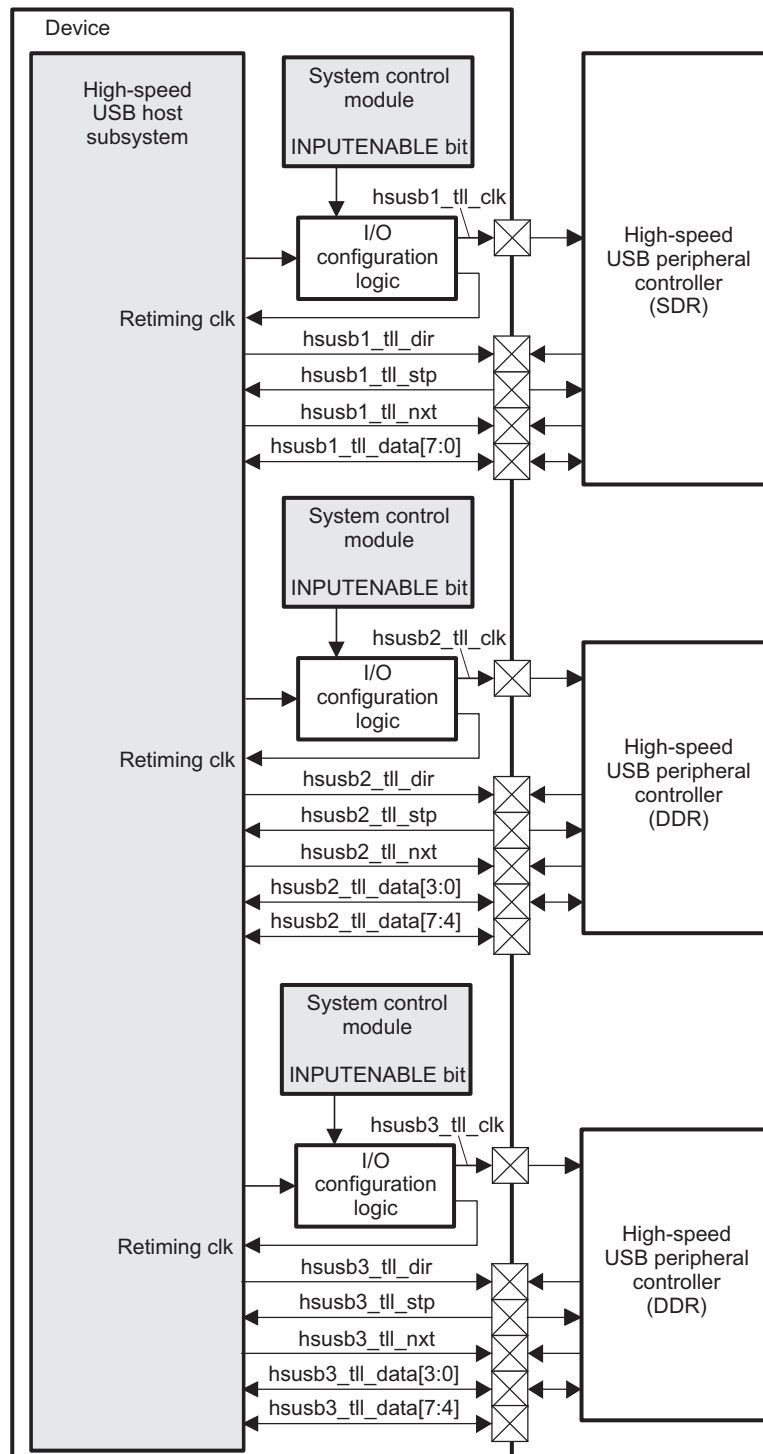

Figure 22-11. High-Speed USB Host Controller Typical Application System - ULPI Interfaces

NOTE: ULPI interfaces: USBTLL is bypassed and high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

usb-010

Figure 22-12. High-Speed USB Host Subsystem Typical Application System - ULPI TLL Interfaces

usb-032

NOTE: ULPI TLL interfaces: The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The current implementation of the ULPI includes a method for manual, software-controlled generation of PHY-side register accesses. This implies support of the following features:

- Access to vendor-specific or optional PHY-side registers
- Access to vendor ID, product ID, and scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode), whereas the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edges (DDR mode).

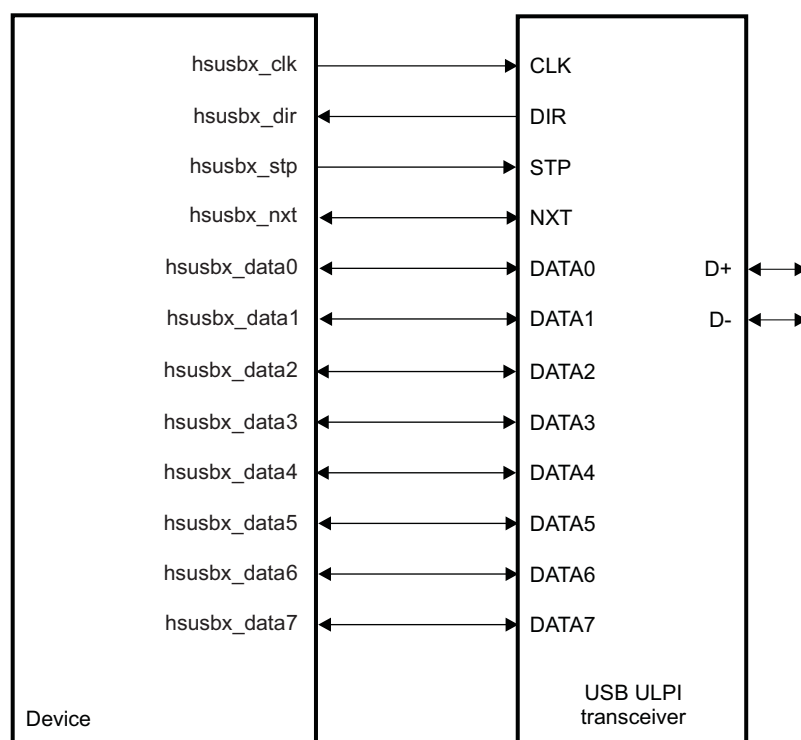

22.2.2.3.1 Transceiver Interface Configurations

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode.

NOTE: In the device, only the ULPI ports 1 and 2 of the high-speed USB host controller are mapped and can be connected directly to external transceivers.

Figure 22-13 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI interface mode.

Figure 22-13. ULPI Interfaces - 12-Pin/8-Bit Data SDR Version

x is the USB port number (1 or 2)

usb-011

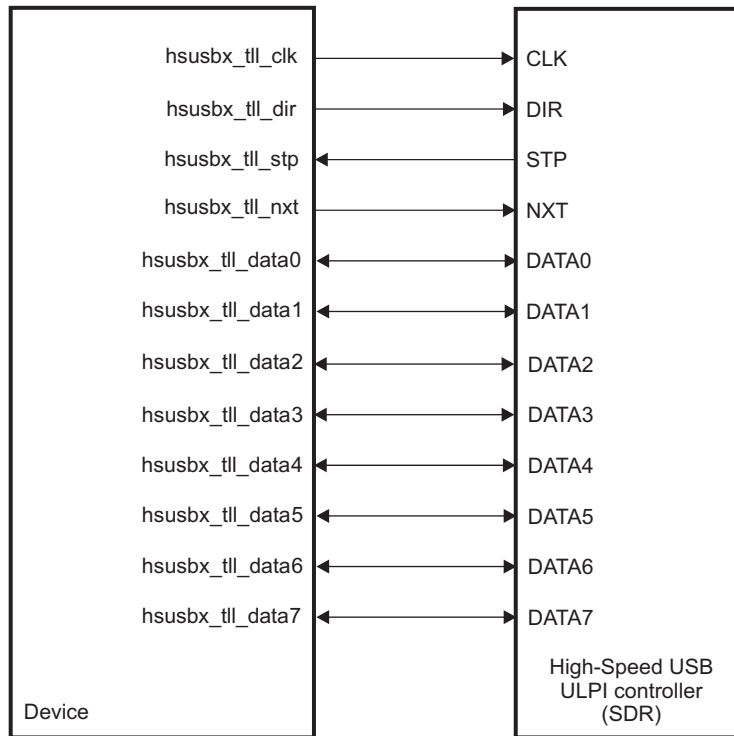

22.2.2.3.2 TLL Configurations

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host subsystem supports the 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions of the ULPI TLL interface mode.

Figure 22-14 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI TLL interface mode.

ULPI (PHY) Interfaces and ULPI TLL Interfaces can not be used together: Either the ULPI (PHY) Interfaces or the ULPI TLL Interfaces are selected.

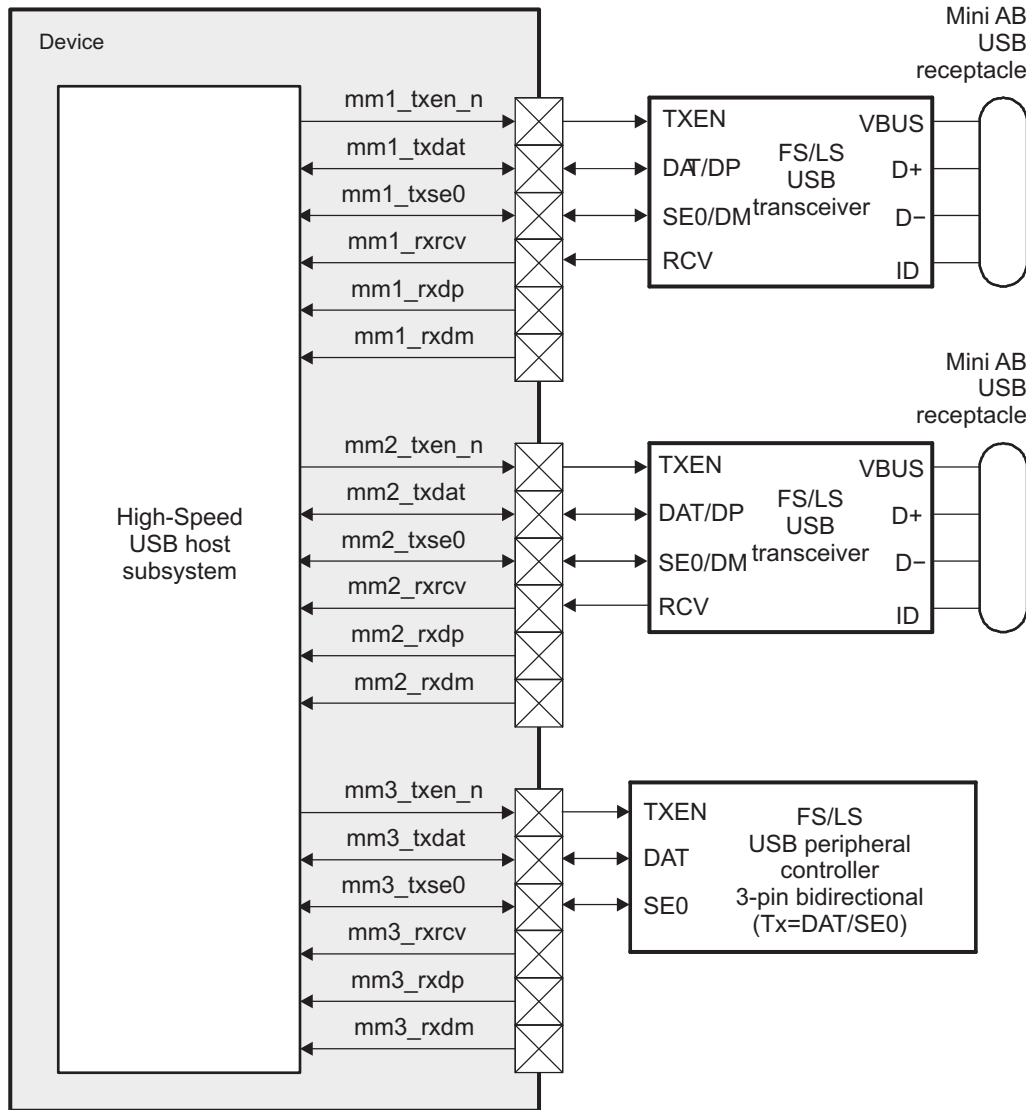

22.2.2.4 Serial Interfaces

The high-speed USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Figure 22-17 shows a typical application using the high-speed USB host subsystem with the serial interfaces.

Figure 22-17. High-Speed USB Host Subsystem Typical Application System

usb-015

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes. The USBTLL module translates the parallel, synchronous UTMI+ (Level 3) protocol to a serial, asynchronous one. The benefit of the conversion is a simplified interface to the transceiver.

CAUTION

Only full- and low-speed data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

CAUTION

It is possible to change the polarity of the TXEN signal for each USB port using the following bits:

- CONTROL. [CONTROL_WKUP_CTRL](#)[2]
M_FSUSB3_TXEN_N_OUT_POLARITY_CTRL
- CONTROL.
[CONTROL_WKUP_CTRL](#)[1]MM_FSUSB3_TXEN_N_OUT_POLARITY_CTRL
- CONTROL. [CONTROL_WKUP_CTRL](#)[0]
M_FSUSB3_TXEN_N_OUT_POLARITY_CTRL

Whether in TLL or transceiver configuration, the serial interface follows the same principles. It is limited to full/low speed, and that high speed requires a parallel interface.

22.2.2.4.1 Encoding in Serial Mode**22.2.2.4.1.1 Unidirectional**

When a USB transceiver is connected to the device and used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 22-26](#) is used.

Table 22-26. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)

22.2.2.4.1.2 Bidirectional

When a USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 22-28](#) is used.

Table 22-28. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description
TXEN	Output	Input	When low, the USB transceiver drives D+ and D–.

Table 22-28. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling (continued)

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description				
DAT and SE0	Output	Input	When TXEN is low/high (depending on the TXEN signal polarity; see the CONTROL. CONTROL_WKUP_CTRL [2, 1 and/or 0] MM_FSUSBi_TXEN_N_OUT_POLARITY_CTR bit), the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0.				
			TXEN	DAT	SE0	D+	D-
				0	0	0	0
	1	0		1	0	0	
	Input	Output	TXEN	D+	D-	DAT	SE0
				0	0	0	1
				0	1	0	0
				1	0	1	0
				1	1	Undefined	0

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

When a USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 22-29](#) is used.

Table 22-29. Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling

Logical Signal Name	Device Pin Direction	Transceiver Pin Direction	Description

RCV	Input	Output	Output from transceiver differential receiver		
			D+	D-	RCV
			0	0	X
			0	1	0
			1	0	1
1	1	X			

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

22.2.2.4.2 Sideband Signals for Serial Modes

Serial interfaces only carry the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D- pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end), etc.
- Sideband signal implementations: Dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I²C, UART, etc.)

Figure 22-18 and Figure 22-19 show system integration for sideband signals for two logically identical USB connections: One in transceiver configuration, and one in TLL configuration. Although the sideband (purple) arrows are all oriented from controller to transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from controller to transceiver [control] but also from transceiver to controller [status]).

Figure 22-18 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- Sideband output signals from the USBTLL module (speed, suspend, puen, etc.)
- The software-driven VBUS reporting procedure is described in Section 22.2.4.2.4.1.1, *VBUS Management in Serial Transceiver Configurations*.

Figure 22-18. Serial Interface Sideband Integration - Transceiver Configuration

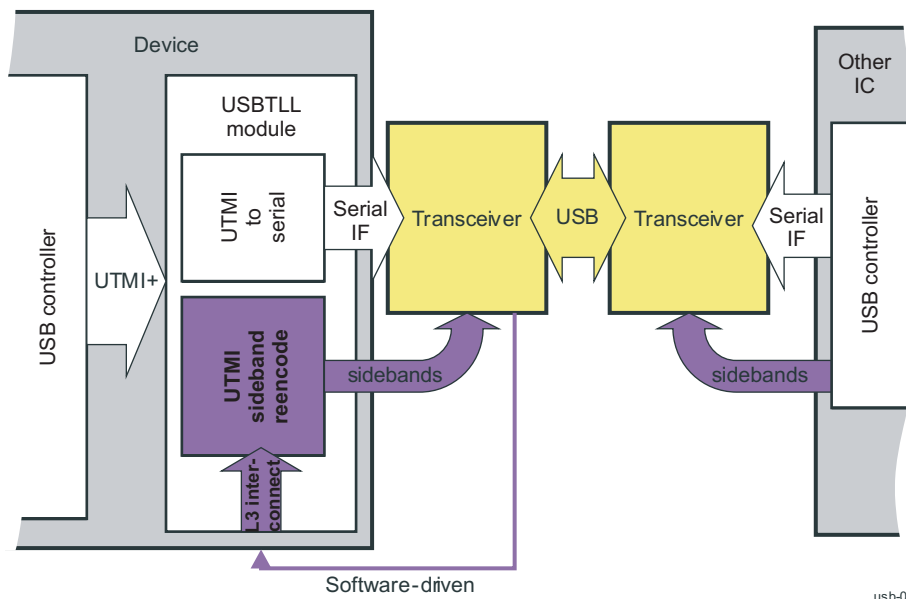

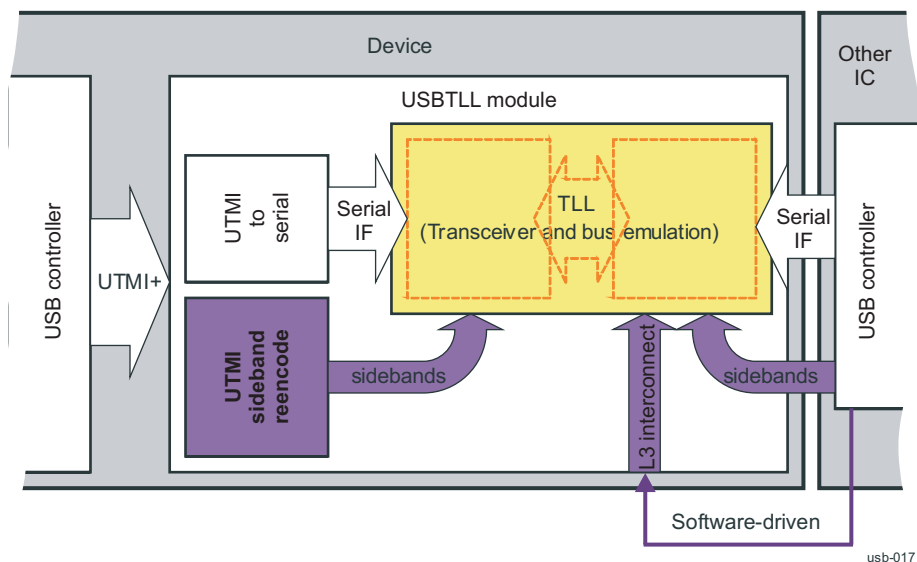

Figure 22-19 shows the TLL configuration, where both transceivers are actually emulated inside the USBTLL module.

- The transceiver of the local controller (left) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right) must communicate with its controller, located on another IC. This is done in two ways:
 - Sideband input signals at the TLL module boundary (tllpuen, tlldrvbus, tllvbusvalid, etc.)

- The software-driven VBUS control procedure is described in [Section 22.2.4.2.4.2.2, VBUS Emulation for TLL Configurations](#)

Figure 22-19. Serial Interface Sideband Integration - TLL Configuration

22.2.2.4.3 Transceiver Interface Configurations

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the high-speed USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the high-speed USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to three external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the high-speed USB subsystem in the serial-interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided either by additional signals or through an I²C link.

The following subsections describe the transceiver interface modes supported by the high-speed USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of which are the actual USB lines (D+/D-).

22.2.2.4.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

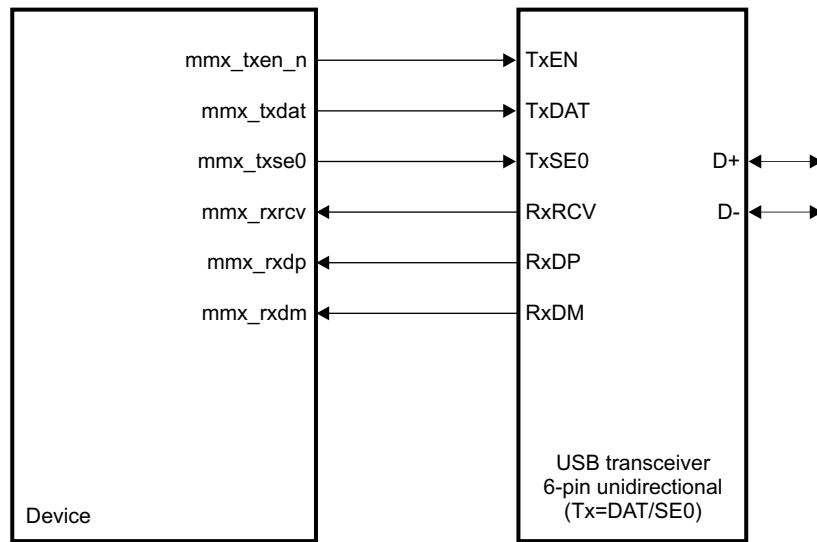

The 6-pin modes are the "natural" transceiver interface modes for the full-speed transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 or DP/DM.

When a USB is connected to the device and used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in [Table 22-26](#) is used.

[Figure 22-20](#) shows a USB port using DAT/SE0 encoding.

Figure 22-20. 6-Pin Unidirectional Using DAT/SE0 Signaling

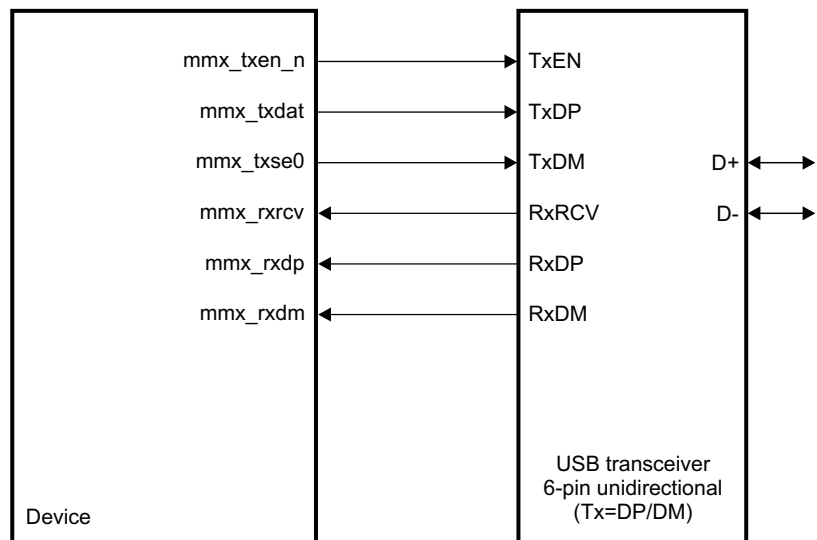

x is the USB port number (1, 2 or 3)

usb-018

When a USB is connected to the device and used in 6-pin unidirectional DP/DM signaling mode, the signaling described in [Table 22-27](#) is used.

[Figure 22-21](#) shows a USB port using DP/DM encoding.

Figure 22-21. 6-Pin Unidirectional Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

usb-019

22.2.2.4.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

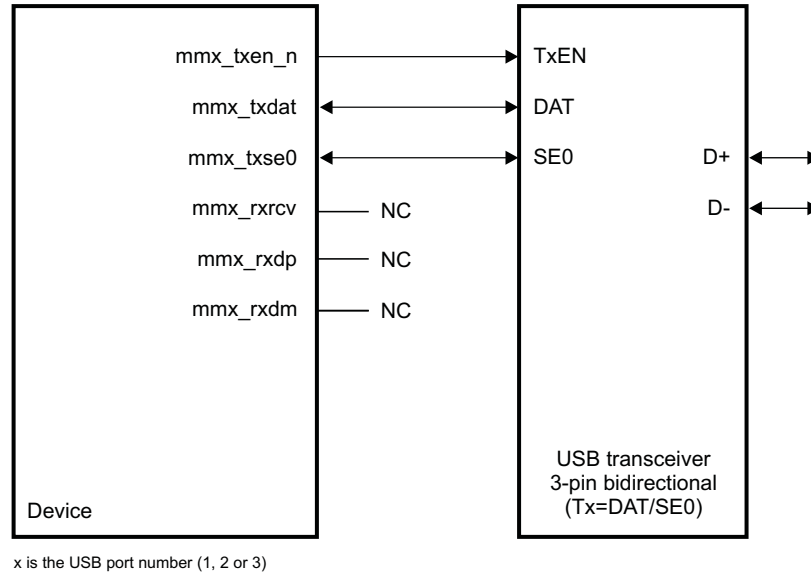

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is either sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling listed in [Table 22-28](#) is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

Figure 22-22 shows a USB port using DAT/SE0 encoding.

Figure 22-22. 3-Pin Bidirectional Using DAT/SE0 Signaling

The signaling listed in Table 22-29 is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

Figure 22-23 shows a USB port using DP/DM encoding.

Figure 22-23. 4-Pin Bidirectional Using DP/DM Signaling

22.2.2.4.4 TLL Configurations

The high-speed USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are full- or low-speed only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

22.2.2.4.4.1 Unidirectional TLL Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 22-24 shows an external device using DAT/SE0 encoding.

Figure 22-24. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

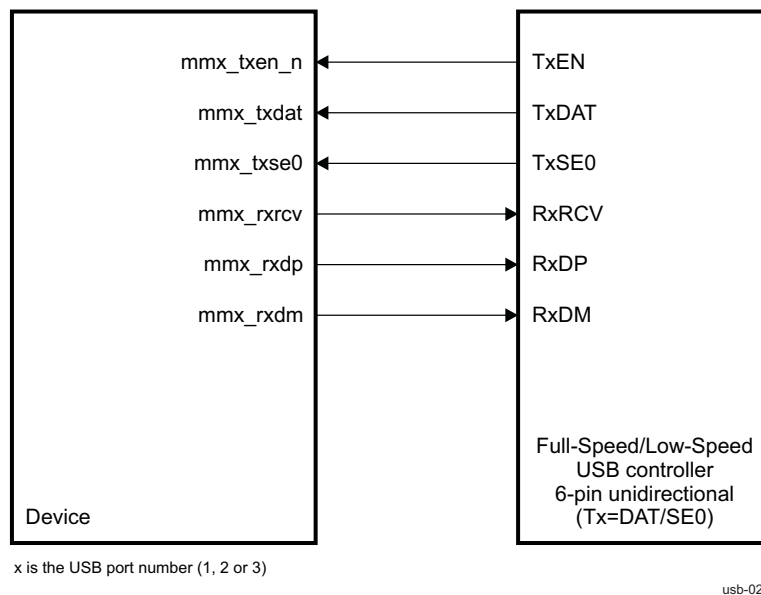

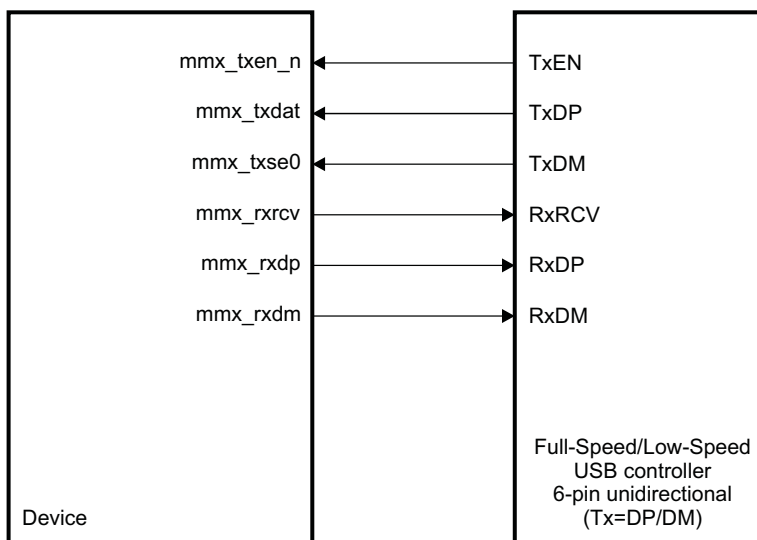

Figure 22-25 shows an external device using DP/DM encoding.

Figure 22-25. 6-Pin Unidirectional TLL Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

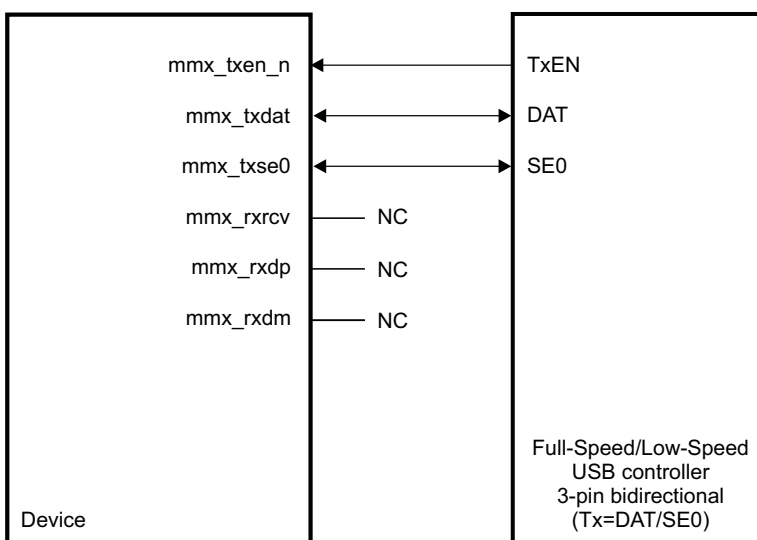

usb-023

22.2.2.4.4.2 Bidirectional TLL Modes

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 22-26 shows an external device using DAT/SE0 encoding.

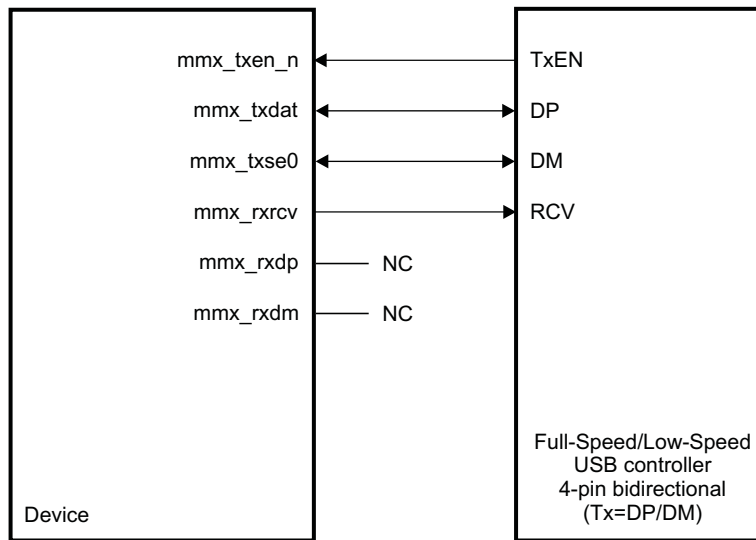

Figure 22-26. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling

x is the USB port number (1, 2 or 3)

usb-024

Figure 22-27 shows an external device using DP/DM encoding.

Figure 22-27. 4-Pin Bidirectional TLL Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

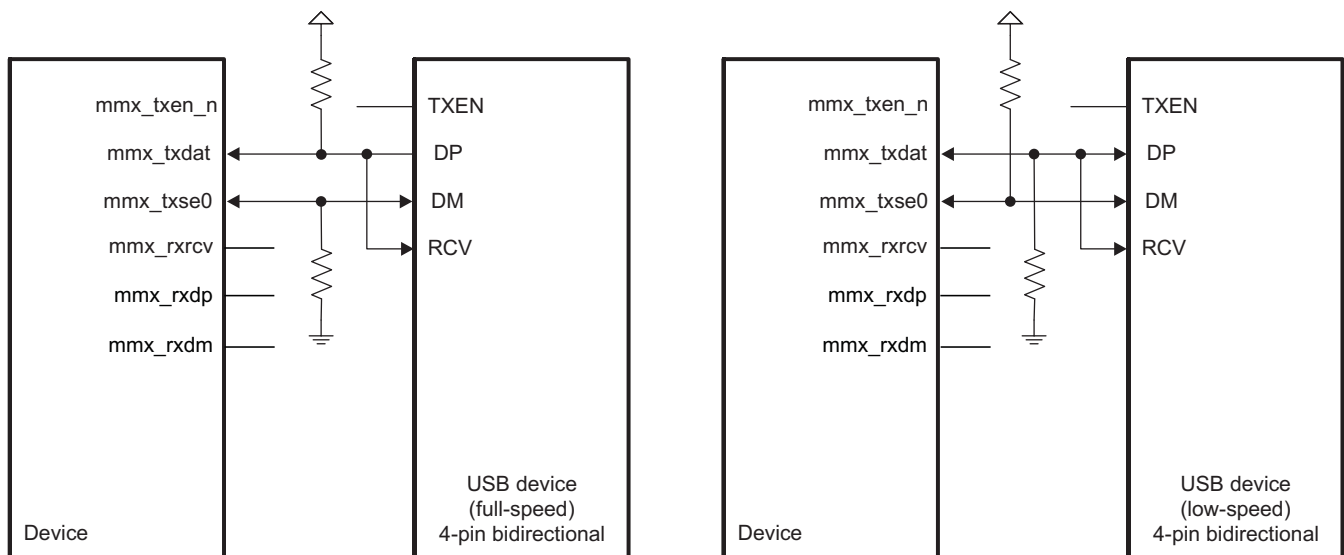

usb-025

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described above. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with either DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 22-28 shows USB port using DP/DM encoding.

Figure 22-28. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device

22.2.3 High-Speed USB Host Subsystem Integration

This section describes the integration of the high-speed USB host subsystem.

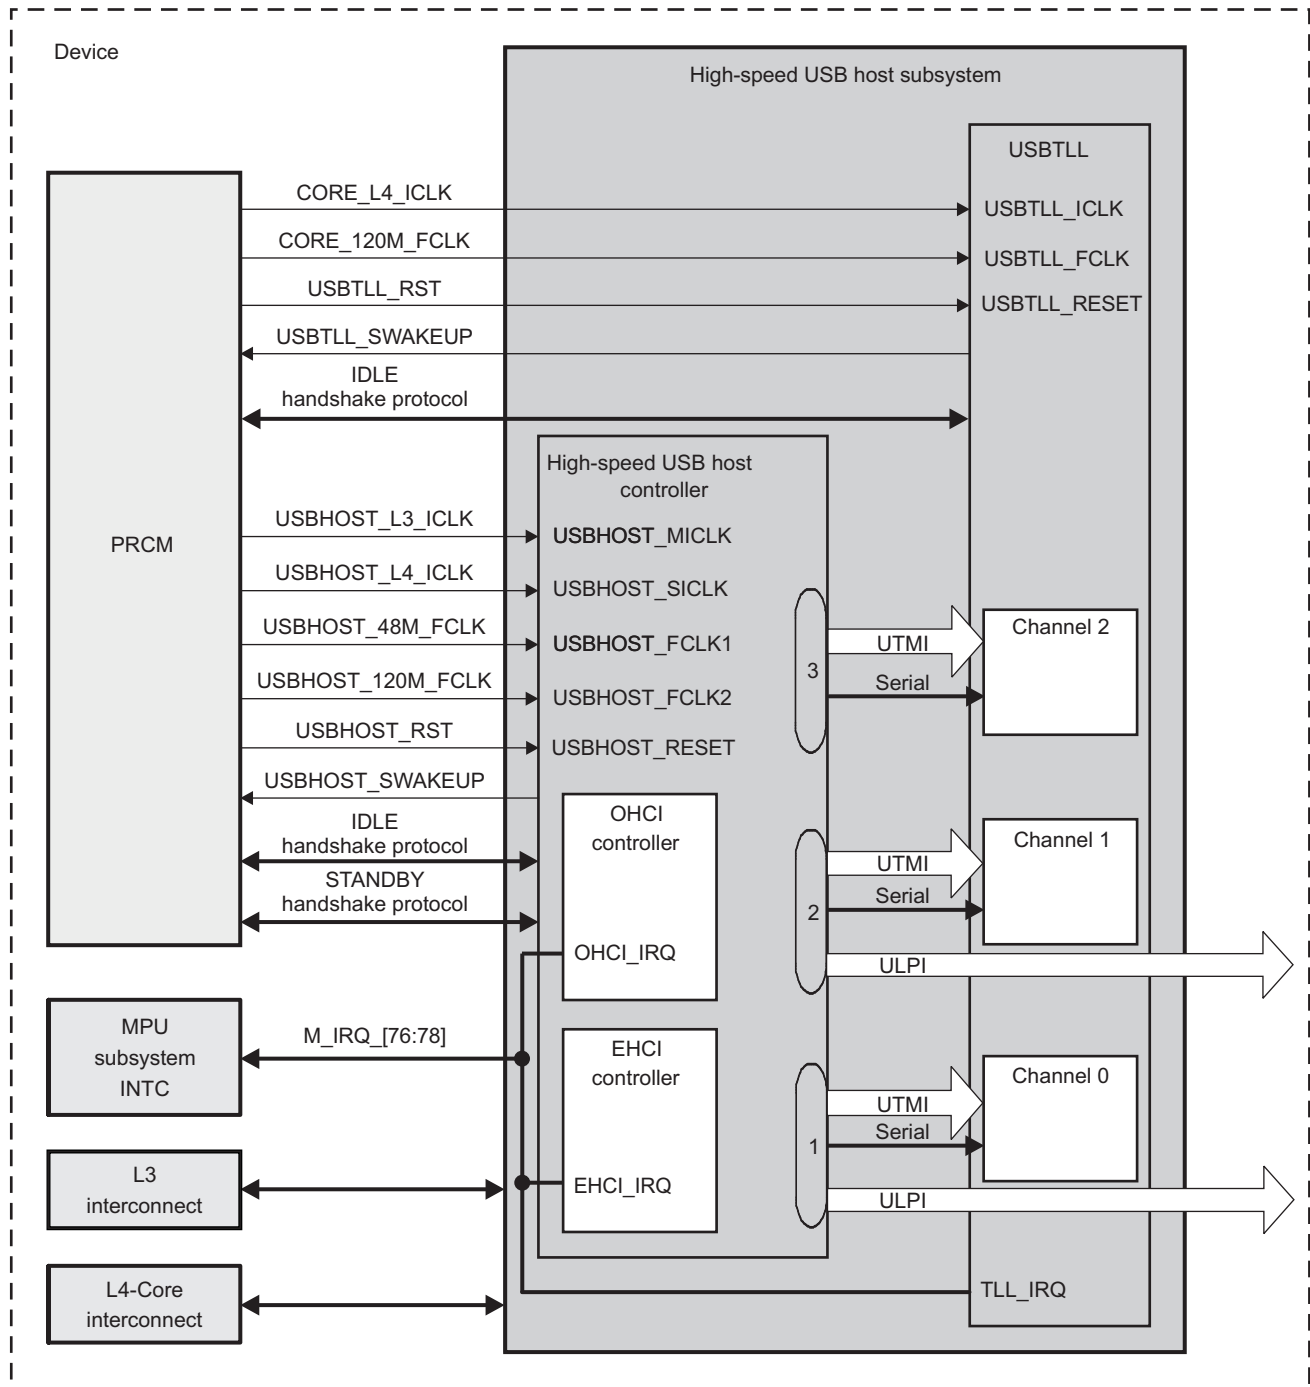

The high-speed USB host controller is connected to the L3 interconnect master (initiator) and L4-Core interconnect slave (target) interfaces. The USBTLL module is connected to the L4-Core interconnect slave (target) interface. The L3 interconnect is used to generate data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Three interrupts, M_IRQ_[78:76], are connected to the system.

The system control module (SCM) offers complementary settings for USB port connectivity modes.

[Figure 22-30](#) highlights the high-speed USB host subsystem integration in the device.

Figure 22-30. High-Speed USB Subsystem Integration

usb-028

22.2.3.1 Reset, Clocking, and Power-Management Scheme

The high-speed USB host controller belongs to the USBHOST power domain. As part of the USBHOST power domain, it is sensible to the USBHOST_RST reset signal issued by the PRCM and to USBHOST power domain-related transitions. For further details about USBHOST power domain implementation and USBHOST_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

The USBTLL module belongs to the CORE power domain. As part of the CORE power domain, it is sensible to the asynchronous USBTLL_RST reset signal issued by the PRCM and to CORE power domain-related transitions. For further details about CORE power domain implementation and USBTLL_RST signal, see [Chapter 3, Power, Reset, and Clock Management](#).

22.2.3.1.1 High-Speed USB Host Subsystem Resets

[Table 22-33](#) lists and describes all the high-speed USB host subsystem resets:

Table 22-33. High-Speed USB Host Subsystem Reset Description

Type	Name	Source	Polarity	Description
Software	USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit	High-speed USB host controller internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Software	USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit	USBTLL module internal software reset	Active high	Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.
Hardware	USBHOST_RESET	PRCM USBHOST_RST signal	Active low	The USBHOST_RST signal resets the module. The hardware reset signal has a global reset action on the high-speed USB host controller (see Chapter 3, Power, Reset, and Clock Management).
Hardware	USBTLL_RESET	PRCM USBTLL_RST signal	Active low	The USBTLL_RST signal resets asynchronously the module. The hardware reset signal has a global reset action on the USBTLL module (see Chapter 3, Power, Reset, and Clock Management).

22.2.3.1.1.1 Hardware Resets

The high-speed USB host controller is attached to the USBHOST power domain: The USBHOST_RST signal resets the module. The USBTLL module is attached to the CORE power domain: The USBTLL_RST signal resets asynchronously the module (see [Chapter 3, Power, Reset, and Clock Management](#)). The hardware reset signal has a global reset action on the modules.

22.2.3.1.1.2 Software Resets

The high-speed USB host controller and the USBTLL module have their own software-reset functionality through the USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit (0: Normal mode; 1: Module is reset) for the high-speed USB host controller, and through the USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit (0: Normal mode; 1: Module is reset) for the USBTLL module.

Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

22.2.3.1.2 High-Speed USB Host Subsystem Clocks

The high-speed USB host controller operates from four clock domains:

- USBHOST_FCLK1 is a high-speed USB host controller functional clock. It is used to clock the OHCI and EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM

USBHOST_48M_FCLK output clock. USBHOST_FCLK1 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit (0: Disabled; 1: Enabled).

- USBHOST_FCLK2 is a high-speed USB host controller functional clock. It is used to clock EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_120M_FCLK output clock. USBHOST_FCLK2 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit (0: Disabled; 1: Enabled).
- USBHOST_MICLK is the high-speed USB host controller L3 master interface clock. It is used to synchronize the high-speed USB host controller L3 port to L3 interconnect. All accesses from the interconnect are synchronous to USBHOST_MICLK. Its source is the PRCM USBHOST_L3_ICLK output clock. USBHOST_MICLK is controlled by the PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit (0: Disabled; 1: Enabled) and the PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit (enables/disables automatic control of the interface clock).
- USBHOST_SICLK is a high-speed USB host controller L4 slave interface clock. It is used to synchronize the high-speed USB host controller L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBHOST_SICLK. Its source is the PRCM USBHOST_L4_ICLK output clock.

The USBTLL module operates from two clock domains:

- USBTLL_FCLK is the USBTLL module functional clock. It is used to clock the USBTLL module internal logic. Its source is the PRCM CORE_120M_FCLK output clock. USBTLL_FCLK is controlled by the PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit (0: Disabled; 1: Enabled).
- USBTLL_ICLK is the USBTLL module interface clock. It is used to synchronize USBTLL module L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBTLL_ICLK. Its source is the PRCM CORE_L4_ICLK output clock. USBTLL_ICLK is controlled by the PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit (0: Disabled; 1: Enabled) and the PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit (enables/disables automatic control of the interface clock).

Table 22-34 summarizes the high-speed USB host subsystem clocks.

Table 22-34. High-Speed USB Host Subsystem Clocks

Attributes	Frequency	Name	Module	Mapping	Comments
Functional clock	48 MHz	USBHOST_FCLK1	High-speed USB Host controller	USBHOST_48M_FCLK	Source is PRCM module
Functional clock	120 MHz	USBHOST_FCLK2	High-speed USB Host controller	USBHOST_120M_FCLK	Source is PRCM module
L3 master interface clock	Depending on PRCM register settings	USBHOST_MICLK	High-speed USB Host controller	USBHOST_L3_ICLK	Source is PRCM module
L4 slave interface clock	Depending on PRCM register settings	USBHOST_SICLK	High-speed USB Host controller	USBHOST_L4_ICLK	Source is PRCM module
Functional clock	120 MHz	USBTLL_FCLK	USBTLL	CORE_120M_FCLK	Source is PRCM module
L4 interface clock	Depending on PRCM register settings	USBTLL_ICLK	USBTLL	CORE_L4_ICLK	Source is PRCM module

22.2.3.1.2.1 L3 Master Interface Clock

The L3 master interface clock (USBHOST_L3_ICLK) is used only by the high-speed USB host controller (USBHOST_MICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN_USBHOST[0]:

0: Disabled
1: Enabled

and PRCM.CM_AUTOIDLE_USBHOST[0] (enables/disables automatic control of the interface clock)-see [Table 22-35](#).

Table 22-35. High-Speed USB Controller L3 Master Interface Clock

PRCM.CM_AUTOIDLE_USBHOST[0]	PRCM.CM_ICLKEN_USBHOST[0]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

CAUTION

The L3 master interface clock should not be below 30 MHz, ULPI clock divided by 2 (this can occur during DPLL3 relocking).

22.2.3.1.2.2 L4 Slave Interface Clock

The L4 slave interface clock (USBHOST_L4_ICLK) is used only by the high-speed USB host controller (USBHOST_SICLK) in the subsystem, and comes from the PRCM module.

22.2.3.1.2.3 L4 Interface Clock

The L4 interface clock (CORE_L4_ICLK) is used only by the USBTLL module (USBTLL_ICLK) in the subsystem, and comes from the PRCM module.

This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN3_CORE[2]:

- 0: Disabled
- 1: Enabled

and PRCM.CM_AUTOIDLE3_CORE[2] (enables/disables automatic control of the interface clock), see [Table 22-36](#).

Table 22-36. USBTLL Module Interface Clock

PRCM.CM_AUTOIDLE3_CORE[2]	PRCM.CM_ICLKEN3_CORE[2]	Interface Clock
0	0	Disabled
0	1	Enabled
1	0	Disabled
1	1	Automatic enabling/disabling

22.2.3.1.2.4 Functional Clocks

Two functional clocks are provided by the PRCM module to the high-speed USB host controller: USBHOST_FLCK1 running at 48 MHz (USBHOST_48M_FCLK) and USBHOST_FLCK2 running at 120 MHz (USBHOST_120M_FCLK).

The USBHOST_FLCK1 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[0]:

- 0: Disabled
- 1: Enabled

The USBHOST_FLCK2 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[1]:

- 0: Disabled
- 1: Enabled

The CORE_120M_FCLK functional clock is used only by the USBTLL module (USBTLL_FCLK) in the subsystem, and comes from the PRCM module.

This clock is controlled by the PRCM register bit PRCM.CM_FCLKEN3_CORE[2]:

- 0: Disabled
- 1: Enabled

22.2.3.1.3 Power-Management Scheme

22.2.3.1.3.1 High-Speed USB Host Controller Power-Management Scheme

22.2.3.1.3.1.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB host controller power management is applied only to the interface clock domain.

The high-speed USB host controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

Table 22-37 details the high-speed USB host controller module PRCM clock control bits.

Table 22-37. High-Speed USB Host Controller PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
USBHOST_FCLK1	USBHOST_48M_FCLK	PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit	N/A
USBHOST_FCLK2	USBHOST_120M_FCLK	PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit	N/A
USBHOST_MICLK	USBHOST_L3_ICLK	PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit	PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit

NOTE:

- The PRCM USBHOST_48M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_120M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_L3_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit is used to link/unlink the high-speed USB host controller from USBHOST_L3_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see [Chapter 3, Power, Reset, and Clock Management](#).

22.2.3.1.3.1.2 L3 Master Interface Power Management

The high-speed USB host controller can go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB host controller has a MSTANDBY/WAIT handshake mechanism with the PRCM module (see [Figure 22-30](#)).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go to standby mode based on the USBHOST.UHH_SYSCONFIG[13:12] MIDLEMODE field.

Table 22-38. High-Speed USB Host Controller MIDLEMODE Settings

MIDLEMODE Value	Selected Mode	Description
0x0	Force-standby	The high-speed USB host controller enters standby mode unconditionally (MSTANDBY is asserted unconditionally).
0x1	No-standby	The high-speed USB host controller never enters standby mode (MSTANDBY is never asserted).
0x2	Smart-standby	The high-speed USB host controller is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

22.2.3.1.3.1.3 L4 Slave Interface Power Management

At PRCM level, when all the conditions to shut off the high-speed USB host controller output clocks are met (see [Chapter 3, Power, Reset, and Clock Management](#) for details), the PRCM module automatically launches a hardware handshake protocol to ensure the high-speed USB host controller is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the high-speed USB host controller. Although this handshake is completely hardware and out of any software control, the way in which the high-speed USB host controller acknowledges the PRCM IDLE request is configurable through the USBHOST.UHH_SYSCONFIG[4:3] SIDLEMODE bit field. [Table 22-39](#) details SIDLEMODE settings and the related acknowledgment modes.

Table 22-39. High-Speed USB Host Controller SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The high-speed USB host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The high-speed USB host controller never acknowledges any IDLE request from the PRCM. This mode is safe from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The high-speed USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the high-speed USB host controller also offers an additional granularity on its interface clock gating. The `USBHOST.UHH_SYSCONFIG[9:8] CLOCKACTIVITY` bit is used to control the interface clock internal gating while module is idle. [Table 22-40](#) details the `CLOCKACTIVITY` settings.

Table 22-40. High-Speed USB Host Controller CLOCKACTIVITY Settings

CLOCKACTIVITY Value	Interface Clock Effect	Description
0	OFF	Interface clock is considered for generating the acknowledgment. This setting also means the interface clock is shut down upon PRCM IDLE request.
1	ON	Interface clock is not shut down upon PRCM IDLE request. The high-speed USB host controller can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read `CLOCKACTIVITY` settings. Software ensures a consistent programming between the high-speed USB host controller `CLOCKACTIVITY` and PRCM interface clock control bit. Indeed, if the `USBTLL` module is disabled in the `PRCM.CM_ICLKEN_USBHOST` register while `CLOCKACTIVITY` is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the `USBTLL` module interface clock. This may lead to unpredictable behaviors.

22.2.3.1.3.2 USBTLL Module Device Power-Management Scheme

From a global system power-management perspective, when one or both of the `USBTLL` module clocks are no longer required, the `USBTLL` module can be deactivated at PRCM level in the corresponding registers.

[Table 22-41](#) details the `USBTLL` module PRCM clock control bits.

Table 22-41. USBTLL Module PRCM Clock Control Bits

Module Clock	Associated PRCM Clock Output	Enabled Bit	Autoidle Bit
<code>USBTLL_FCLK</code>	<code>CORE_120M_FCLK</code>	<code>PRCM.CM_FCLKEN3_CORE[2] EN_USBTTLL</code> bit	N/A
<code>USBTLL_ICLK</code>	<code>CORE_L4_ICLK</code>	<code>PRCM.CM_ICLKEN3_CORE[2] EN_USBTTLL</code> bit	<code>PRCM.CM_AUTOIDLE3_CORE [2] AUTO_USBTTLL</code> bit

NOTE:

- The PRCM CORE_120M_CLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM CORE_L4_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit is used to link/unlink the USBTLL module from CORE_L4_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see [Chapter 3, Power, Reset, and Clock Management](#).

At PRCM level, when all the conditions to shut off the USBTLL_FCLK or USBTLL_ICLK output clocks are met (see [Chapter 3, Power, Reset, and Clock Management](#) for details), the PRCM module automatically launches a hardware handshake protocol to ensure the USBTLL module is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the USBTLL module. Although this handshake is completely hardware and out of any software control, the way in which the USBTLL module acknowledges the PRCM IDLE request is configurable through the USBHOST.USBTLL_SYSCONFIG[4:3] SIDLEMODE bit field. [Table 22-42](#) details SIDLEMODE settings and the related acknowledgment modes.

Table 22-42. USBTLL Module SIDLEMODE Settings

SIDLEMODE Value	Selected Mode	Description
0x0	Force-idle	The USBTLL module acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully.
0x1	No-idle	The USBTLL module never acknowledges any IDLE request from the PRCM. This mode is safe from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
0x2	Smart-idle	The USBTLL module acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the USBTLL module also offers an additional granularity on USBTLL_ICLK gating. The USBHOST.USBTLL_SYSCONFIG[9:8] CLOCKACTIVITY bit is used to control the USBTLL_ICLK clock internal gating while the module is idle. [Table 22-43](#) details the CLOCKACTIVITY settings.

Table 22-43. USBTLL Module CLOCKACTIVITY Settings

CLOCKACTIVITY Value	USBTLL_ICLK Effect	Description
0	OFF	USBTLL_ICLK is considered for generating the acknowledgment. This setting also means USBTLL_ICLK is shut down upon PRCM IDLE request.
1	ON	USBTLL_ICLK is not shut down upon PRCM IDLE request. The USBTLL module can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock.

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the USBTLL module CLOCKACTIVITY and PRCM USBTLL_ICLK control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN3_CORE register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

22.2.3.2 Hardware Requests**22.2.3.2.1 Interrupt Requests**

Table 22-44 lists the interrupt lines that are driven out from the high-speed USB host controller to the microprocessor unit (MPU) subsystem interrupt controller (INTC).

Table 22-44. High-Speed USB Host Subsystem Interrupts

Name	Mapping	Comments
HS USB OHCI Host Controller Interrupt		
OHCI_IRQ	M_IRQ_76	Destination is MPU subsystem interrupt controller
HS USB EHCI Host Controller Interrupt		
EHCI_IRQ	M_IRQ_77	Destination is MPU subsystem interrupt controller
USBTLL Module Interrupt		
TLL_IRQ	M_IRQ_78	Destination is MPU subsystem interrupt controller

22.2.3.2.2 IDLE Handshake Protocol

The PRCM handles an IDLE handshake protocol for the high-speed USB host controller and the USBTLL module. The IDLE handshake protocol allows the PRCM requiring the high-speed USB host controller to enter idle mode. The module acknowledges when it is ready.

22.2.3.2.3 MSTANDBY Handshake Protocol

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB host controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

22.2.3.2.4 Wake-Up Request

Wake-up request signal USBHOST_SWAKEUP is generated by the high-speed USB host controller to the PRCM module. Wake-up request signal USBTLL_SWAKEUP is generated by the USBTLL module to the PRCM module.

22.2.4 High-Speed USB Host Subsystem Functional Description

This section describes the functionality of the high-speed USB host subsystem by describing the high-speed USB host controller and the USBTLL module.

22.2.4.1 High-Speed USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following public specifications:

- *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*

22.2.4.1.1 High-Speed USB Host Controller Architecture

[Figure 22-31](#) shows an overview of the high-speed USB host controller internal architecture: It contains two independent, 3-port host controllers that operate in parallel: EHCI and OHCI. Each of the three external ports is owned by exactly one of the controllers at any point in time. Each port can work in several modes:

- When the port is owned by the OHCI (full-speed) host controller, the serial 6-pin interface mode is used.
- When the port is owned by the EHCI (high-speed) host controller, either the ULPI or the UTMI modes are used.

The L4-Core interconnect is used to configure the two controllers, as well as a general, TI-specific register bank. The L3 interconnect merges and arbitrates between the transactions generated by the controller respective DMA engines.

Figure 22-31. High-Speed USB Host Controller Architecture

usb-029

22.2.4.1.2 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the high-speed USB host controller, are described below, and are reflected in the register descriptions (see [Section 22.2.6.4.3, OHCI Registers](#)). For all standard features, see the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*.

- `USBHOST.HCFMINTERVAL[30:16]` FSMPs field (FullSpeedMaxPacketSize) = 0x0000: Host will stop scheduling new packets 0 bit times before the end of the frame (that is, there is no scheduling overrun protection by default). To be updated by the software driver.
- `USBHOST.HCRHDESCRIPTORA[7:0]` NDP field (NumberDownstreamPorts) = 0x03 = 3 ports.
- `USBHOST.HCRHDESCRIPTORA[9]` NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.
- `USBHOST.HCRHDESCRIPTORA[8]` PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally (default must be = OCPM).
- `USBHOST.HCRHDESCRIPTORA[31:24]` POTPG field (PowerOnToPowerGood) = 0x0A = 10: Power

rampup time is $10 \times 2 \text{ ms} = 20 \text{ ms}$.

- USBHOST.HCRHDESCRIPTORB[15:0] DR field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.
- USBHOST.HCRHDESCRIPTORB[31:16] PPCM field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

22.2.4.1.3 UTMI Ports

The high-speed USB host controller supports N "downstream" ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an "upstream" port, and because the host is on "top" of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see each port configuration with the USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS, USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS, and USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bits).

In UTMI mode (see *USB 2.0 Transceiver Macrocell Interface specification Release 1.05*), all ports are in UTMI mode (that is, each port has its UTMI signal set broadcast the "outgoing" packets - from the host to the peripherals) and gather the "incoming" ones (that is, from the addressed peripheral to the host). ULPI signal sets are undefined/don't care on all ports.

In the device, the UTMI ports connect to the USBTLL module. The UTMI ports between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible.

22.2.4.1.4 ULPI Ports

The high-speed USB host controller supports N "downstream" ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an "upstream" port, and because the host is on "top" of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see each port configuration with the USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS, USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS, and USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bits).

In ULPI mode, all ports are in ULPI mode (that is, each port has its ULPI signal set broadcast the "outgoing" packets - from the host to the peripherals) and gather the "incoming" ones (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don't care on all ports.

When in ULPI mode, the high-speed USB host controller is in charge of generating the (nominally 60-MHz) clock to the transceiver on the ULPI interface. This is called ULPI "input" clocking mode, because the ULPI protocol is transceiver-centric. The opposite mode, "output mode" (that is, the host receives the ULPI clock from the transceiver), is not supported and there is consequently no ULPI clock input.

In the device, the ULPI ports can only be connected directly to external transceivers. The USBTLL module is bypassed. USB traffic can be monitored directly on the USB lines.

22.2.4.1.5 Port Status

The USB port status is given through the USBHOST.UHH_HOSTCONFIG[10:8] bit field. The default value of the following bits is 1:

- USBHOST.UHH_HOSTCONFIG[8] P1_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[9] P2_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[10] P3_CONNECT_STATUS

CAUTION

These bits show the port status as connected after power on even though no USB device is connected. The USB host controller has operational status registers (for example, USBHOST.HCRHPORTSTATUS_1 for OHCI port 1) that indicate the correct port connect status. The USB driver software must read these status bits and check whether or not a port is connected. If the port is not connected, the USB driver software must reprogram the USBHOST.UHH_HOSTCONFIG bits to indicate the correct port connect status.

22.2.4.1.6 Save and Restore

The save-and-restore (SAR) mechanism can extract the hardware context of the high-speed USB host controller (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the "buried" flip-flops and memories (not accessible by software) like finite state-machine (FSM) states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_USBHOSTE[4] SAVEANDRESTORE bit enables the SAR mechanism for the high-speed USB host controller (see [Chapter 3, Power, Reset, and Clock Management](#)). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

22.2.4.1.7 L3 Burst Control

To avoid buffer underflow, bursts must be enabled by writing 0x7 in the USBHOST.UHH_HOSTCONFIG[4:2] bit field and by setting the USBHOST.UHH_HOSTCONFIG[5] ENA_INCR_ALIGN bit to 1.

22.2.4.2 USBTLL Module Functionality

The USBTLL module implements a TLL compatible with a number of USB standard interface protocols. Once the interface protocol has been selected during an initial configuration phase, USB operation should take place seamlessly (that is, as if actual transceivers were present). To ensure maximum compatibility, as many features as possible have been included, as described in the rest of this document. The basic principle is that all the software "handles" should be available and behave in a proper way, even if there is no actual functionality underneath.

The USBTLL module is integrated with the high-speed USB host controller in the device. The transceiver interfaces (UTMI ports) between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible. The other transceiver interfaces go off-chip, where they can be connected to the other controllers (for example, peripherals) on another IC.

22.2.4.2.1 Channels and Ports

Following the same convention than UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL), and not with respect to the link controller: An "input" goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module. Reciprocally, an "output" goes from TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the high-speed USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the high-speed USB host controller in the device). The number of channels of the USBTLL module is three in the device.

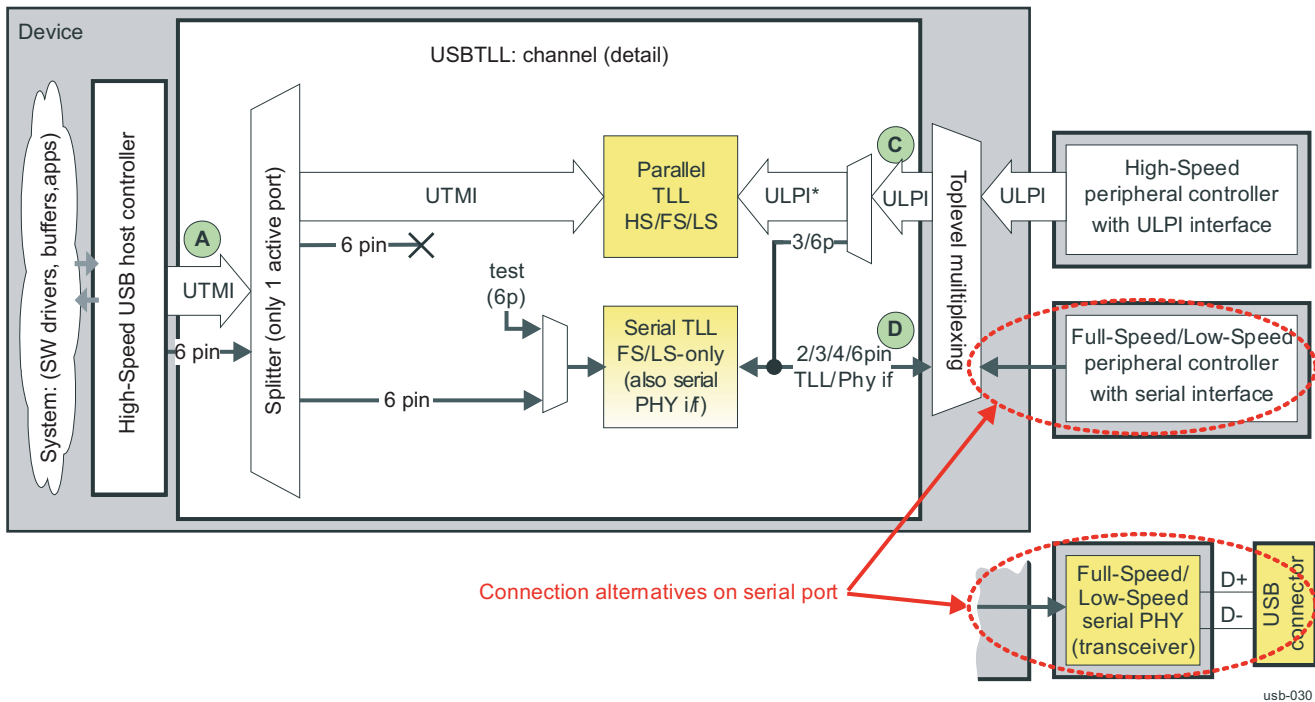

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at a time, depending on the channel configuration. The mode remains static throughout USB operation. Table 22-45 summarizes the ports features.

22.2.4.2.2 Channel Architecture

Figure 22-32 shows the architecture of a single channel (of three) of the USBTLL module, and its integration in a USB system. The ports are indicated by the circled letters (A, C, and D). See the following descriptions:

- Full arrows represent parallel, synchronous, high-speed-capable interfaces.
- Line arrows represent serial, combinatorial, full-speed/low-speed-only interfaces.
- Arrows always point toward the PHY layer (actual transceiver or TLL, in yellow), away from the link controller.
- The arrow marked ULPI* represents the entire ULPI protocol (synchronous or not) except the 3-/6-pin serial TLL modes which are reoriented toward the serial TLL block.
- The USBTLL module cannot interface with a ULPI transceiver. This functionality is provided by the high-speed USB host controller.
- Top-level multiplexing is shown only for information. It is static and does not add functionality. The figure shows ULPI and serial ports implemented on different I/O pads for clarity, but a real implementation would typically reuse the same pads, because the interfaces cannot be active simultaneously

Figure 22-32. USBTLL Channel

usb-030

Table 22-45 summarizes the properties of each port.

Table 22-45. USBTLL Channel USB Ports

USBTLL Port	Port Description	Connect to Controller	Connect to Transceiver	Serial (Full-Speed/Low-Speed only)	Parallel (High-Speed/Full-Speed/Low-Speed)
A	PHY-side UTMI+	UTMI+ (L3)	No	6-pin	60-MHz UTMI
C	PHY-side ULPI	ULPI TLL	No	6-pin	60-MHz UTMI
D	Multimode Serial	6-/4-/3-/2-pin TLL	6-/4-/3-/2-pin	6-/4-/3-/2-pin TLL	No

22.2.4.2.2.1 Port A: PHY-side UTMI+ Port

Connects to the high-speed USB host controller in the device. The UTMI "local" port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the remote ports C or D).

- Compliant with UTMI+ version 1.0
- 8-data-bit, 60 MHz UTMI (HS/FS/LS-capable)
- UTMI+ Level 3 extensions
- Vcontrol/Vstatus (from UTMI)
- Serial FS/LS "6-pin" mode

22.2.4.2.2.2 Port C: PHY-Side ULPI Port

Connects to a remote (off-chip) ULPI controller through I/O pads.

- Compliant with ULPI version 1.1
- SDR and DDR ULPI capable (respectively, 8-bit/4-bit data width modes)
- Supports optional 6-pin/3-pin serial modes

22.2.4.2.2.3 Port D: Serial Multimode Port

Connects to either a serial controller (TLL modes) or a serial transceiver (transceiver interface modes).

- Supports 6-pin (TX: DAT/SE0 or TX: DP/DM) unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
- All modes are supported for TLL or transceiver interface configuration.
- Supports sideband signals (pullup/down control, speed/suspend enable, etc.)

22.2.4.2.3 Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 22-46](#), lists the modes.

All configurations connect the PHY UTMI port (attached to the high-speed USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pads side).

[Table 22-46](#) describes the available modes and the software settings required for each. Channel *i* has the following settings:

- CHANMODE: USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field
- FLSMODE: USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field
- FLS SERIALMODE_3PIN/6PIN: Either the ULPI PHY-side USBHOST.ULPI_INTERFACE_CTRL_i[1] FLS SERIALMODE_3PIN bit or the USBHOST.ULPI_INTERFACE_CTRL_i[0] FLS SERIALMODE_6PIN bit (only one can be set to 1 at a time)

Table 22-46. USBTLL Channel Configuration

Configuration	Mode	CHAN MODE	FLSMODE	Other Settings	Ports	Speed	Remote Port Connection
2	ULPI synchronous TLL	0	N/A	FLS SERIALMODE_3PIN/6PIN = 0	A-C	HFL	ULPI link (peripheral controller)
4	Serial UTMI to serial ULPI TLL	0	N/A	FLS SERIALMODE_3PIN/6PIN = 1	A-C	FL	ULPI link (peripheral controller) supporting 3-/6-pin mode
6	Serial UTMI to serial TLL	1	0x4 to 0x7; 0xA to 0xB	-	A-D	FL	Serial link (2-/3-/4-/6-pin)

Table 22-46. USBTLL Channel Configuration (continued)

Configuration	Mode	CHAN MODE	FSLSMODE	Other Settings	Ports	Speed	Remote Port Connection
6	Serial UTMI to serial PHY	1	0x0 to 0x3	-	A-D	FL	Serial transceiver (2-/3-/4- /6-pin)

Figure 22-33. Per-Configuration Datapath Through USBTLL

22.2.4.2.4 VBUS Management and Emulations

In transceiver configurations, an actual USB cable is present, including an actual 5 V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power saving compared to simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see [Figure 22-18](#) and [Figure 22-19](#) and the related explanations.

22.2.4.2.4.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to/from the actual VBUS manager IC (typically the transceiver itself).

Only serial transceiver configurations are concerned in the case of the high-speed USB host subsystem in the device.

22.2.4.2.4.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described below. See also [Figure 22-18](#).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup "charge", VBUS pulldown "discharge") is assumed to be taken care of separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver itself, especially in OTG cases).
- VBUS status must be sampled by the appropriate hardware (again, most of the time the transceiver itself) and reported by software to the USBTLL module, using the `USBHOST.TLL_CHANNEL_CONF_i` `DRVVBUS` and `CHRGVBUS` bits, as indicated in [Table 22-47](#).

[Table 22-47](#) lists the values to write to the `USBHOST.TLL_CHANNEL_CONF_i` register depending on the VBUS status observed by the transceiver on the actual VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations the fields' actual signification is:

- `DRVVBUS`: Set to 1 to report a VBUS level greater than *VBUS valid*.
- `CHRGVBUS`: Set to 1 to report a VBUS level greater than *Session valid*

Table 22-47. VBUS Level Software Reporting for Serial Transceiver Configuration

VBUS Status	USBHOST.TLL_CHANNEL_CONF_i[16] DRVVBUS Bit	USBHOST.TLL_CHANNEL_CONF_i[15] CHRGVBUS Bit
VBUS valid	1	1
Session valid (A/B)	0	1
Session not valid	0	0
Session end	0	0

22.2.4.2.4.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line, obtains a voltage level, reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas a real VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.

- The Charge feature is used for VBUS-pulsing SRP, and is enabled long enough to go over the Session valid threshold, but without reaching VBUS valid. In the TLL the transition to Session valid is immediate, and VBUS valid is never reached even if the Charge is intentionally kept active.
- The Discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS towards the session-end level. For TLL, this is therefore useless (although the UTMI input/ULPI register bit do exist, for compatibility), and always a "don't care"

22.2.4.2.4.2.1 VBUS Emulation in ULPI TLL Modes

Table 22-48 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

Table 22-48. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode

VBUS Controls (Actions)			VBUS Level	VBUS Status		
USBHOST.ULPI_OTG_CTRL[5] DRVVBUS Bit	USBHOST.ULPI_OTG_CTRL[4] CHRGVBUS Bit	USBHOST.ULPI_OTG_CTRL[3] DISCHRGVBUS Bit		USBHOST.ULPI_USB_INT_STATUS[1] VBUSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[2] SESSVALID Bit	USBHOST.ULPI_USB_INT_STATUS[3] SESEND Bit
1	X	X	VBUS valid	1	1	0
0	1	X	VBUS valid	0	1	0
0	0	X	Session end	0	0	1

22.2.4.2.4.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad-hoc sideband signals. See Figure 22-19.

VBUS control can be done in software, by writing to the following fields of the USBHOST.TLL_CHANNEL_CONF_i register:

- DRVVBUS: Set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: Set to 1 to pullup VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (DRVVBUS register bit and input signal are actually ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at top level, a software alternative is to use the voltage status reported on the local controller (the high-speed USB host controller in the device) interface (through the standard UTMI+ sideband signals) and to pass it to the remote controller (a peripheral controller), by means of an ad hoc software-controller interface other than the USB itself. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

22.2.4.2.5 Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are full-speed/low-speed only (that is, high-speed is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output enable signal associated to it on the USBTLL entity.

Table 22-49 shows the functionality of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

Table 22-49. Serial Mode Description, Signal Functionality

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL (Alt) Mode	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
USBHOST.TLL_CHANNE_CONF_i[27:24] FLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DAT/SE0	DP/DM
Pin usage	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Pin count	6	6	3	4	6 or 5 ⁽¹⁾	6 or 5 ⁽¹⁾	3	4 or 3 ⁽²⁾	2	2
I/O Pad Function Per Mode										
TXEN	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	TX Enable	N/C	N/C
TXDAT	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX SE Plus Data	TX Diff Data	TX SE Plus Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX Diff Data	TX/RX SE Plus Data
TXSE0	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX SE Minus Data	TX force SE0	TX SE Minus Data	TX/RX force SE0	TX/RX force SE0	TX/RX force SE0	TX/RX SE Minus Data
RXRCV	RX Diff Data	RX Diff Data	N/C	RX Diff Data	RX Diff Data	RX Diff Data	N/C	RX Diff Data	N/C	N/C
RXDM	RX SE Plus Data	RX SE Plus Data	N/C	N/C	RX SE Plus Data	RX SE Plus Data	N/C	N/C	N/C	N/C
RXDM	RX SE Minus Data	RX SE Minus Data	N/C	N/C	RX SE Minus Data	RX SE Minus Data	N/C	N/C	N/C	N/C

⁽¹⁾ RXRCV and RXDM carry the same info: RXDM can drive both inputs of the remote controller and RXRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RXRCV: TXDAT only is enough

22.2.4.2.6 Attach/Connect Emulation for Serial TLL Modes

This section applies to all serial TLL modes:

- In UTMI-to-serial mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1) for all TLL values of USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field (0x4 to 0x7; 0xA to 0xB)
- In UTMI-to-ULPI TLL mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x0) when the ULPI bus is switched to 6-pin serial or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic, and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one was implemented:

- USBHOST.TLL_CHANNEL_CONF_i[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable.
 - When this bit is cleared, the local controller RX path only shows the local controller (the high-speed USB host controller) actions on the bus: TX driving, pullups, pulldowns (see below). The same thing applies for the remote controller RX path (except that test override is not available).
 - As soon as the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- USBHOST.TLL_CHANNEL_CONF_i[5] TLLCONNECT bit emulates the USB electrical connect (that is,

the pullup by the USB peripheral of one of the two USB lines [by a 1.5kOhm resistor]), which causes the linestate to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal - the connect control can be software (L4-Core interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit below.

- USBHOST.TLL_CHANNEL_CONF_i[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as defined above) results in the pulling-up of either D+ (1 = full speed) or D- (0 = low speed): See [Table 22-50](#).
- The 15kOhm pulldowns are implicit: Because they are supposed to be turned on at least on the host side of the bus, they do not require an additional control.

NOTE: Sideband control and status actions like pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require any custom additions.

Table 22-50. Pullup Enable Emulation in Serial TLL Modes

USBHOST.TLL_CHANNEL_CONF_i Fields		Input Signal	Resulting TLL Pullup Emulation	
TLLFULLSPEED	TLLCONNECT	USB State	D+ Pullup	D- Pullup
1	0	Full-speed unconnected	Off	Off
1	1	Full-speed connected	on	Off
0	0	Low-speed unconnected	Off	Off
0	1	Low-speed connected	Off	On

22.2.4.2.7 Save and Restore

The SAR mechanism can extract the hardware context of the USBTLL module (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the buried flip-flops and memories (not accessible by software) like FSM states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit enables the SAR mechanism for the USBTLL module (see [Chapter 3, Power, Reset, and Clock Management](#)). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

[Table 22-51](#) lists the USBTLL registers impacted by the SAR context.

NOTE: Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

Table 22-51. USBTLL Registers Impacted by the SAR Context

Register Name	Comments on SAR Policy
USBTLL_SYSCONFIG	Except the SOFTRESET bit (write-only)

22.2.5 High-Speed USB Host Subsystem Basic Programming Model

22.2.5.1 Selecting and Configuring USB Connectivity

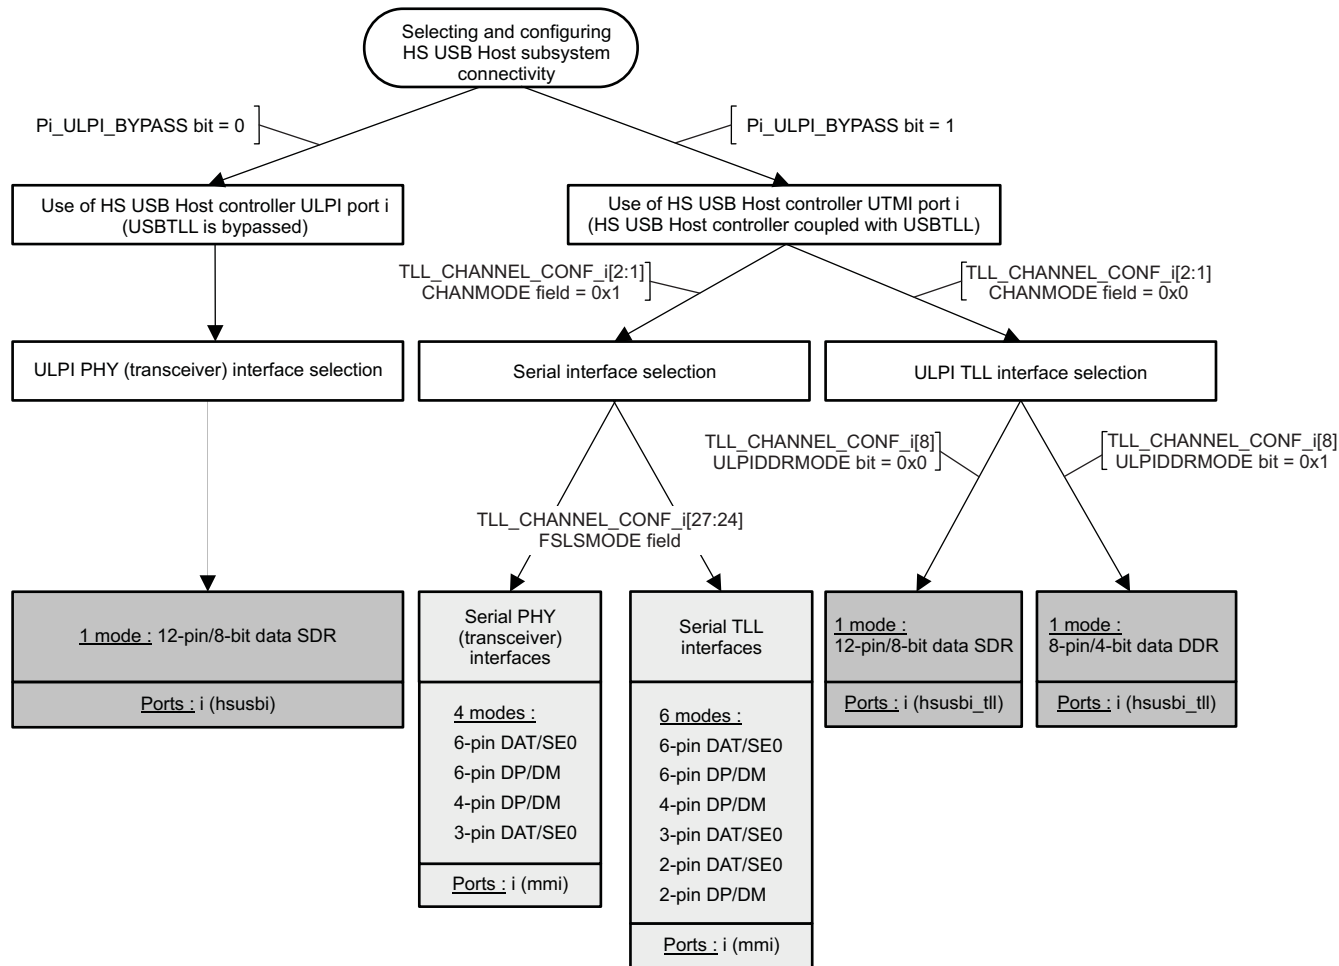

Perform the following steps to select the desired USB connectivity and configure the device accordingly.

The high-speed USB host subsystem provides three kinds of interfaces for connection:

- ULPI PHY interfaces for high-speed data transactions (up to 480 Mbps)
- Serial interfaces for full- and low-speed data transactions (up to 12 Mbps)
- ULPI TLL interfaces for high-speed data transactions (up to 480 Mbps)

[Figure 22-34](#) shows how to select and configure the high-speed USB host subsystem connectivity.

Table 22-53. Subprocess Call Summary for Selecting and Configuring High-Speed USB Host Subsystem Connectivity

Subprocess Name	Cross reference
UHH_HOSTCONFIG[12] Pi_ULPI_BYPASS	Section 22.2.4.1.3, UTMI Ports
TLL_CHANNEL_CONF_i[2:1] CHANMODE	Section 22.2.4.2.3, Channel Configurations
TLL_CHANNEL_CONF_i[27:24] FLSMODE	Section 22.2.4.2.6, Attach/Connect Emulation for Serial TLL Modes
TLL_CHANNEL_CONF_i[8] ULPIDDRMODE	Section 22.2.5.1.1, ULPI Interface Selection

NOTE:

- When the USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS bit is 0 (the port 3 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 3.
- When the USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS bit is 0, (the port 2 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 2.
- When the USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit is 0 (the port 1 ULPI transceiver interface selection), only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported for port 1.
- When the USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS bit is 1, (the ULPI TLL interface selection and serial interface selection), there is no restriction and port 3 can be configured in any ULPI TLL or serial mode.
- When the USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS bit is 1 (the ULPI TLL interface selection and serial interface selection), there is no restriction and port 2 can be configured in any ULPI TLL or serial mode.
- When the USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit is 1 (ULPI TLL interface selection and serial interface selection), there is no restriction and port 1 can be configured in any ULPI TLL or serial mode.

22.2.5.1.1 ULPI Interface Selection

The high-speed USB host subsystem supports the following modes with the ULPI interfaces:

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data version
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data version or 8-pin/4-bit data version

22.2.5.1.1.1 Transceiver Interfaces

The USBTLL module is bypassed and the high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode. The high-speed USB host controller uses its ULPI ports (UTMI ports cannot be used). The USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS, USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS, or USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit must be cleared to 0, depending on the port used in ULPI mode.

22.2.5.1.1.2 TLL

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports). The USBHOST.UHH_HOSTCONFIG[12] P3_ULPI_BYPASS, USBHOST.UHH_HOSTCONFIG[11] P2_ULPI_BYPASS, or USBHOST.UHH_HOSTCONFIG[0] P1_ULPI_BYPASS bit must be set to 1, depending on the port used in UTMI mode.

At the USBTLL module level, a channel configuration for ULPI TLL interfaces must be set (see [Section 22.2.4.2.3, Channel Configurations](#)).

Two configurations are supported for ULPI TLL interfaces in the device:

- Configuration 2: ULPI synchronous TLL mode
- Configuration 4: Serial UTMI to serial ULPI TLL mode

In both configurations, the USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field must be cleared to 0x0 (UTMI-to-ULPI TLL mode).

The selection of the ULPI TLL interface version, 12-pin/8-bit data version (SDR mode) or 8-pin/4-bit data version (DDR mode) is done through the `USBHOST.TLL_CHANNEL_CONF_i[8]` ULPIDDRMODE bit (0: SDR mode; 1: DDR mode).

22.2.5.1.2 Serial Interface Selection

The high-speed USB host subsystem supports the following modes with the serial interfaces:

- External USB transceiver configurations
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional and 3-pin bidirectional modes
- TLL configurations
 - Serial 6-pin TLL interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional, 3-pin bidirectional, and 2-pin bidirectional modes

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports). The `USBHOST.UHH_HOSTCONFIG[12]` P3_ULPI_BYPASS, `USBHOST.UHH_HOSTCONFIG[11]` P2_ULPI_BYPASS, or `USBHOST.UHH_HOSTCONFIG[0]` P1_ULPI_BYPASS bit must be set to 1, depending on the port. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for serial interfaces must be set (see [Section 22.2.4.2.3, Channel Configurations](#)).

One configuration is supported for serial interfaces in the device, the Configuration 6 including two modes:

- Serial UTMI to serial TLL
- Serial UTMI to serial PHY

The multimode-mode serial interface mode selection is done through the `USBHOST.TLL_CHANNEL_CONF_i[27:24]` FLSMODE field only when the main channel mode is serial (`USBHOST.TLL_CHANNEL_CONF_i[2:1]` CHANMODE field = 0x1 = UTMI-to-serial mode).

Table 22-54. USB Connectivity Mode Description

Usual Name	6-Pin Mode	6-Pin Mode (Alt)	3-Pin Mode	4-Pin Mode	6-Pin TLL Mode	6-Pin TLL Mode (Alt)	3-Pin TLL Mode	4-Pin TLL Mode	2-Pin TLL Mode	2-Pin TLL (Alt) Mode
<code>USBHOST.TLL_CHANNEL_CONF_i[27:24]</code> FLSMODE field	0x0	0x1	0x2	0x3	0x4	0x5	0x6	0x7	0xA	0xB
TX encoding	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM	DAT/SE0	DP/DM
RX encoding	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DP/DM/R CV	DP/DM/R CV	DAT/SE0	DP/DM/R CV	DAT/SE0	DP/DM
Pin usage	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Unidirectional	Unidirectional	Bidirectional	Bidirectional	Bidirectional	Bidirectional
Pin count	6	6	3	4	6 or 5 ⁽¹⁾	6 or 5 ⁽¹⁾	3	4 or 3 ⁽²⁾	2	2

⁽¹⁾ RxRCV and RxDP carry the same info: RxDP can drive both inputs of the remote controller and RxRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RxRCV: TXDAT only is enough

22.2.5.2 USBTLL Registers

The USBTLL module contains two types of software-programmable registers.

22.2.5.2.1 TLL Control and Status Registers

These 32-bit registers configure the various channels. These registers are accessed by the MPU through the L4-Core interconnect. They are used mostly before the actual USB activity starts. These registers are:

- Standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

22.2.5.2.2 ULPI PHY-side Registers

Each TLL channel emulates a ULPI transceiver and accordingly contains this set of 8-bit PHY-side registers, per ULPI specification. Those registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in ULPI specification

Those registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

Those registers are accessible by the L4-Core interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4-Core interconnect address space, where they can be accessed through byte accesses. In case of conflict between the two access modes, the access over ULPI will have priority, but both accesses will eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4-Core interconnect accesses could compromise proper USB operation. The L4-Core interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. Upon resume, the ULPI register contents have been lost and can be restored over L4-Core interconnect before USB operations restarts, provided they have been saved elsewhere beforehand.

22.2.6 High-Speed USB Host Subsystem Register Manual

22.2.6.1 USBTLL ULPI PHY-Side Register Space

Each ULPI port emulates a separate ULPI transceiver and as such gives access to a single set of ULPI PHY-side registers, mapped in a separate ULPI register space as specified in the ULPI specification. The ULPI protocol defines two register access methods: Immediate and extended.

- The immediate space maps ULPI PHY-side registers in a 0x40- (64-) byte space (address is 6 bits wide). All ULPI PHY-side registers implemented in the USBTLL implementation are in the immediate space.
- The extended register space maps all ULPI PHY-side registers in a 0x100- (256-) byte space (address is 8 bits wide). The immediate space is remapped at the bottom of the extended space (that is, the extended access method can be used to access any ULPI register).

An access is recognized as extended by first pointing to a reserved dummy address 0x2F (EXTENDED_SET_ACCESS in [Table 22-56](#)). Immediate-mode accesses to this address over the ULPI interface are forbidden by the protocol and the USBTLL behavior is then undefined. Extended accesses to this address have no effect.

Some physical registers are accessible at more than one address, where write accesses perform different actions on the register value: (over-)write, set, clear. A read to any of the addresses returns the register value. The names of the set and clear registers are the write name postfixed with respectively `_SET` and `_CLR`. The register fields are described only once, at the write address (see [Section 22.2.6.4.1, USBTLL Registers](#)).

NOTE: Some ULPI registers are cleared upon read.

22.2.6.2 L4-Core Interconnect Register Space

[Table 22-55](#) lists the base address and address space for the high-speed USB host subsystem.

Table 22-55. High-Speed USB Host Subsystem Instance Summary

Module Name	Base Address (hex)	Size
USBTLL	0x4806 2000	4096 bytes
UHH_config	0x4806 4000	1024 bytes
OHCI	0x4806 4400	1024 bytes
EHCI	0x4806 4800	1024 bytes

22.2.6.3 High-Speed USB Host Subsystem Register Summary

The USBTLL single L4-Core interconnect gives access to both the TLL control and status registers, and the ULPI PHY-side registers.

[Table 22-56](#) lists all the USBTLL registers mapped by the L4-Core interconnect, for the maximum 8-channel configuration.

CAUTION

On ULPI PHY-side register access over L4-Core interconnect:

ULPI registers are byte-sized, and can only be accessed in this size. Attempts to access them over L4-Core interconnect using any other data size (16- or 32-bit) will complete without error (or any other warning), but will result in undefined behaviors.

The following cases can cause problems:

- If the ULPI register contents are defined as static (nonvolatile) by the software, a cache update may result in a burst of 32-bit access, with unwanted consequences.
- Some registers have adjacent overwrite, set, and clear addresses. An oversized write access could clear and set the same bit, which can have several results.
- Some registers are cleared on read: Oversized read accesses to adjacent memory locations could cause unwanted clears.

Table 22-70. TLL_SHARED_CONF

Address Offset	0x0000 0030	Instance	USBTLL
Physical Address	0x4806 2030		
Description	Common control register for all TLL channels		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
RESERVED																												USB_90D_DDR_EN	USB_180D_SDR_EN	USB_DIVRATIO	FCLK_REQ	FCLK_IS_ON

Bits	Field Name	Description	Type	Reset
31:7	RESERVED	Reserved	R	0x0000000
6	USB_90D_DDR_EN	Software enable/disable of the 90-degree phase shift scheme on output DDR data, when implemented. Read-only, always-0 when HDL generic ULPI_90DEG4DDR = 0. 0x0: ULPI DDR output DATA aligned with CLK 0x1: ULPI DDR output DATA delayed by 90 degree wrt CLK	RW	0x1
5	USB_180D_SDR_EN	Software enable/disable of the 180-degree phase shift scheme on output SDR data, when implemented. Read-only, always-0 when HDL generic ULPI_180DEG4SDR = 0 0x0: ULPI SDR output DATA aligned with CLK 0x1: ULPI SDR output DATA delayed by 180 degree wrt CLK	RW	0x1
4:2	USB_DIVRATIO	(Log2 of) division ratio from functional clock to USB (UTMI/ULPI) clock 0x0: Div ratio is 2**0 = 1 : Bypass 0x1: Div ratio is 2**1 = 2 0x2: Div ratio is 2**2 = 4 0x3: Div ratio is 2**3 = 8 0x4: Div ratio is 2**4 = 16 0x5: Div ratio is 2**5 = 32 0x6: Div ratio is 2**6 = 64 0x7: Div ratio is 2**7 = 128	RW	0x0
1	FCLK_REQ	Functional clock request, ORed from all channels depending on their respective USB bus state. Combined with the Fclk_is_on status to generate fclk_start/end IRQs. 0x0: Func clock input is not requested by TLL 0x1: Func clock input is requested by TLL	R	0x0
0	FCLK_IS_ON	Status of the functional clock input, provided by the system to the TLL module. The TLL module will only use that clock if the current status indicated that it is ready. Combined with the Fclk_request to generate fclk_start/end IRQs. 0x0: Functional clock input is not guaranteed ON (can actually be ON, OFF, or unstable) 0x1: Functional clock input is guaranteed ON and stable	RW	0x0

Bits	Field Name	Description	Type	Reset
31:30	RESERVED	Reserved	R	0x0
29:28	FSLSLINESTATE	Line state for Full/Low speed serial modes Bit1 = D- / Bit0 = D+ 0x0: Single-ended 0 0x1: Full-Speed J = differential 1 0x2: Full-Speed K = differential 0 0x3: Single-ended 1 (illegal in USB)	R	0x0
27:24	FSLSMODE	Multiple-mode serial interface's mode select. Only when main channel mode is serial. No effect in other main modes. 0x0: "6pin" unidirectional PHY i/f mode. TX encoding is Dat/Se0 (default) 0x1: "6-pin" unidirectional PHY i/f mode. TX encoding is Dp/Dm 0x2: "3-pin" bidirectional PHY i/f mode. 0x3: "4-pin" bidirectional PHY i/f mode. 0x4: "6pin" unidirectional TLL mode. TX encoding is Dat/Se0 0x5: "6pin" unidirectional TLL mode. TX encoding is Dp/Dm 0x6: "3-pin" bidirectional TLL mode. 0x7: "4-pin" bidirectional TLL mode. 0xA: "2-pin" bidirectional TLL mode. Encoding is Dat/Se0 0xB: "2-pin" bidirectional TLL mode. Encoding is Dp/Dm	RW	0x0
23:21	RESERVED	Reserved	R	0x0
20	TESTTXSE0	Force-Se0 transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) 0x0: Drive differential value on TX according to TestTXDat 0x1: Drive SE0 on TX	RW	0x0
19	TESTTXDAT	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) or TestSe0 = 1 (tx = se0) 0x0: Drive full-speed K = differential 0 0x1: Drive full-speed J = differential 1	RW	0x0

Bits	Field Name	Description	Type	Reset
18	TESTTXEN	Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive TX according to TestTXDat/Se0 0x1: Drive TX Hiz (no drive: Pullups determine line state)	RW	0x0
17	TESTEN	Enable manual test override for serial mode TX path (from local controller's UTMI port) 0x0: No override. TX is from local link controller 0x1: Override enabled	RW	0x0
16	DRVVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5V	RW	0x0
15	CHRGVBUS	VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge/pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid	RW	0x0
14:12	RESERVED	Reserved	R	0x0
11	ULPINOBITSTUFF	Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (non-standard)	RW	0x0
10	ULPIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes	RW	0x1
9	UTMIAUTOIDLE	For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMI goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend	RW	0x1
8	ULPIDDRMODE	Select single/double data rate (SDR/DDR) mode for ULPI TLL Reset value depends on hardware generics ULPI_SDR/DDR_MODE. 0x0: SDR mode (8 data bit/12 pin) 0x1: DDR mode (4 data bit/8 pin)	RW	0x0
7	ULPIOUTCLKMODE	ULPI clocking mode select for ULPI TLL ChanMode 0x0: ULPI clock provided by LINK (that is, off-chip). ULPI clock is input 0x1: ULPI clock provided by PHY side (that is, TLL, from functional clock). ULPI clock is output	RW	0x1
6	TLLFULLSPEED	Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: Input m(N)_tlpuen, register field TllConnect. 0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup	RW	0x1

Bits	Field Name	Description	Type	Reset
5	TLLCONNECT	Emulation of Full/Low-Speed connect (that is, D+ resp D– pullup) for serial TLL modes. Speed is determined by field TllSpeed. 0x0: Unconnected 0x1: Connected	RW	0x0
4	TLLATTACH	Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: Cable detach emulated on serial TLL 0x1: Cable attach emulated on serial TLL	RW	0x1
3	UTMIISADEV	Select the cable end "seen" by UTMI side of TLL, that is, the emulated USB cable's orientation. Note that host must always be on A side, Peripheral on B side. Reset value depends on generic DEFUTMIISHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral	RW	0x1
2:1	CHANMODE	Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): To ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: To serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: To UTMI PHY 0x3: No mode selected	RW	0x0
0	CHANEN	Active-high channel enable. A disabled channel is unlocked and kept under reset. 0x0: Channel #N disabled 0x1: Channel #N enabled	RW	0x0

19	RESERVED	Reserved	RW	0
18	PSSC	Port 3 suspend status change. This bit is set when the Port 3 port suspend status has changed. Write 0x0: No effect. Write 0x1: Clears this bit.	RW	0
17	PESC	Port 3 enable status change. This bit is set when the Port 3 port enable status has changed. Write 0x0: No effect. Write 0x1: Clears this bit.	RW	0

Bits	Field Name	Description	Type	Reset
16	CSC	Port 3 connect status change. This bit is set when the Port 3 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect. Write 0x1: Clears this bit. Note: If the DR bit HCRHDESCRIPTORB[1] is set, this bit is set only after a root hub reset to inform the system that the device is attached.	RW	0
15:10	RESERVED	Reserved	R	0x00
9	LSDA_CPP	Port 3 low-speed device attached/clear port power. This bit is valid only when port 3 current connect status is 1. Read 0x0: A full-speed device is attached to port 3. Read 0x1: A low-speed device is attached to port 3. Write 0x0: No effect. Write 0x1: Clears the port 3 port power status.	RW	0
8	PPS_SPP	Port 3 power status/set port power. Read 0x0: Port 3 power is enabled. Read 0x1: Port 3 power is not enabled. Write 0x0: No effect. Write 0x1: Sets the port 3 port power status bit.	RW	0
7:5	RESERVED	Reserved	R	0x0
4	PRS_SPR	Port 3 reset status/set port reset. Read 0x0: USB reset is not being sent to port 3. Read 0x1: Port 3 is signaling the USB reset. Write 0x0: No effect. Write 0x1: Sets the port 3 port reset status bit and causes the USB host controller to begin signaling USB reset to port 3.	RW	0
3	RESERVED	Reserved	RW	0
2	PSS_SPS	Port 3 port suspend status/set port suspend. This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect. Read 0x0: Port 3 is not in the USB suspend state. Read 0x1: Port 3 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 3 current connect status is 1, sets the port 3 port suspend status bit and places port 3 in USB suspend state. If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port.	RW	0
1	PES_SPE	Port 3 enable status/set port enable. This bit is automatically set at completion of port 3 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 3 is not enabled. Read 0x1: Port 3 is enabled. Write 0x0: No effect. Write 0x1: When port 3 current connect status is 1 sets the port 3 port enable status bit. When port 3 current status is 0 has no effect.	RW	0
0	CCS_CPE	Port 3 current connection status/clear port enable. Read 0x0: No USB device is attached to port 3. Read 0x1: Port 3 currently has a USB device attached. Write 0x0: No effect. Write 0x1: Clears the port 3 port enable bit. Note: This bit is set to 1 if the DR bit HCRHDESCRIPTORB[1] is set to indicate a non-removable device on port 3.	RW	0

Bits	Field Name	Description	Type	Reset
31:16	RESERVED	Reserved	R	0x0000
15	ASS	<p>Asynchronous Schedule Status</p> <p>The bit reports the current real status of the asynchronous schedule.</p> <p>0x0: The status of the asynchronous schedule is disabled.</p> <p>0x1: The status of the asynchronous schedule is enabled.</p>	R	0
14	PSS	<p>Periodic Schedule Status</p> <p>The bit reports the current real status of the periodic schedule.</p>	R	0

Bits	Field Name	Description	Type	Reset
		0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled.		
13	REC	Reclamation It is used to detect an empty asynchronous schedule.	R	0
12	HCH	Host Controller Halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware.	R	1
11:6	RESERVED	Reserved	R	0x00
5	IAA	Interrupt on Async Advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 in the USBHOST.USBCMD[6] IAAD bit. This status bit indicates the assertion of that interrupt source.	RW	0
4	HSE	Host System Error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module.	RW	0
3	FLR	Frame List Rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size.	RW	0
2	PCD	Port Change Detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_i[13] PO bit is set to 0 has a change bit transition from a 0 to a 1 or a USBHOST.PORTSC_i[6] FPR bit transition from a 0 to a 1. This bit is also set as a result of the USBHOST.PORTSC_i[1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by writing a 1 to a USBHOST.PORTSC_i[13] PO bit.	RW	0
1	USBEI	USB Error Interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition.	RW	0
0	USBI	USB Interrupt The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).	RW	0

13	PO	Port Owner This bit unconditionally goes to a 0x0 when the USBHOST.CONFIGFLAG[0] CF bit makes a 0 to 1 transition. This bit unconditionally goes to 0 whenever the USBHOST.CONFIGFLAG[0] CF bit is 0. 0x1: A companion host controller owns and controls the port.	RW	1						
12	PP	Port Power The function of this bit depends on the value of the USBHOST.HCSPARAMS[4] PPC bit. The behavior is as follows: <table border="1"> <thead> <tr> <th>PPC</th> <th>PP</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>0x1</td> <td>Host controller does not have port power. control switches. Each port is hard-wired to power.</td> </tr> </tbody> </table>	PPC	PP	Operation	0x0	0x1	Host controller does not have port power. control switches. Each port is hard-wired to power.	RW	0
PPC	PP	Operation								
0x0	0x1	Host controller does not have port power. control switches. Each port is hard-wired to power.								

High-Speed USB Host Subsystem

www.ti.com

Bits	Field Name	Description	Type	Reset															
		0x1 N/A Host controller has port power control switches. This bit represents the current setting of the switch (0 = Off, 1 = On). When an overcurrent condition is detected on a powered port and the USBHOST.HCSPARAMS[4] PPC bit is a 1, the PP bit in each affected port may be transitioned by the host controller from 1 to 0.																	
11:10	LS	Line Status These bits reflect the current logical levels of the D+ (bit 11) and D– (bit 10) signal lines. This field is valid only when the port enable bit is 0 and the current connect status bit is set to 1. The encoding of the bits is: <table border="1"> <thead> <tr> <th>Bits[11:10]</th> <th>USB State</th> <th>Interpretation</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>SE0</td> <td>Not low-speed device, perform EHCI reset.</td> </tr> <tr> <td>0x2</td> <td>J-state</td> <td>Not low-speed device, perform EHCI reset.</td> </tr> <tr> <td>0x1</td> <td>K-state</td> <td>Low-speed device, release ownership of port.</td> </tr> <tr> <td>0x3</td> <td>Undefined</td> <td>Not low-speed device, perform EHCI reset.</td> </tr> </tbody> </table>	Bits[11:10]	USB State	Interpretation	0x0	SE0	Not low-speed device, perform EHCI reset.	0x2	J-state	Not low-speed device, perform EHCI reset.	0x1	K-state	Low-speed device, release ownership of port.	0x3	Undefined	Not low-speed device, perform EHCI reset.	R	0x0
Bits[11:10]	USB State	Interpretation																	
0x0	SE0	Not low-speed device, perform EHCI reset.																	
0x2	J-state	Not low-speed device, perform EHCI reset.																	
0x1	K-state	Low-speed device, release ownership of port.																	
0x3	Undefined	Not low-speed device, perform EHCI reset.																	
9	RESERVED	Reserved	R	0															
8	PR	Port Reset This field is 0 if the PP bit is 0. 0x0: Port is not in reset. 0x1: Port is in reset. Write 0x0: Terminate the bus reset sequence. Write 0x1 when at 0x0: The bus reset sequence is started.	RW	0															
7	SUS	Suspend This field is 0 if the PP bit is 0. 0x0 when PED = 0x1: Port enabled 0x1 when PED = 0x1: Port in suspend state When PED = 0x0: Port disabled	RW	0															
6	FPR	Force Port Resume This field is 0 if the PP bit is 0. 0x0: No resume (K-state) detected/driven on port 0x1: Resume detected/driven on port	RW	0															
5:4	RESERVED	Reserved	RW	0															
3	PEDC	Port Enabled/Disabled Change This field is 0 if the PP bit is 0. Read 0x0: No change. Read 0x1: Port enabled/disabled status has changed. Write 0x1: Clears this bit to 0.	RW	0															
2	PED	Port Enabled/Disabled Software cannot enable a port by writing a 1 to this field. The host controller only sets this to 1 when the reset sequence determines that the attached device is a high-speed device. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by host software. This field is 0 if the PP bit is 0. 0x0: Disable 0x1: Enable	RW	0															
1	CSC	Connect Status Change Indicates a change has occurred in the port CCS bit. This field is 0 if the PP bit is 0. Read 0x0: No change	RW	0															

Bits	Field Name	Description	Type	Reset
		Read 0x1: Change in current connect status Write 0x1: Clears this bit to 0		
0	CCS	Current Connect Status This value reflects the current state of the port, and may not correspond directly to the event that caused the CSC bit to be set. This field is 0 if the PP bit is 0. 0x0: No device is present. 0x1: Device is present on port.	R	0

Memory Stick PRO Host Controller

This chapter presents an overview of the Memory Stick PRO™ host controller in the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
23.1 Memory Stick PRO Host Controller Overview	3376

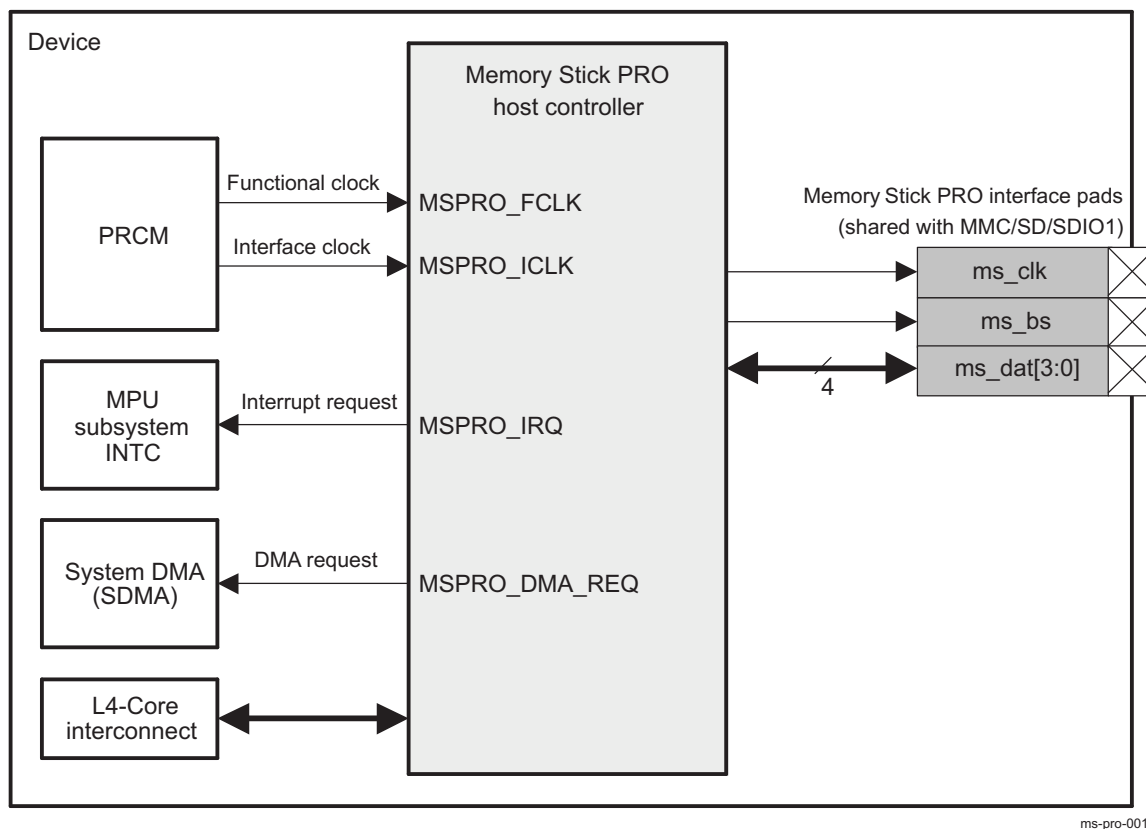

23.1 Memory Stick PRO Host Controller Overview

The Memory Stick PRO host controller provides the device with an interface between a microprocessor unit (MPU) local host (LH) and either a Memory Stick® or a Memory Stick PRO card.

The Memory Stick PRO host controller is connected to the L4-Core interconnect.

Figure 23-1 shows an overview of the Memory Stick PRO host controller.

Figure 23-1. Memory Stick PRO Host Controller Overview

23.1.1 Main Features

The Memory Stick PRO host controller includes the following main features:

- Supports Memory Stick v1.x and Memory Stick PRO
- Data transmit/receive internal first-in first-out (FIFO) (64 bits x 4)
- Cyclic redundancy check (CRC) circuit
- Memory Stick serial clock (Memory Stick v1.x: 19.2 MHz; Memory Stick PRO: 32 MHz with 96-MHz functional clock source)
- Direct memory access (DMA) supported
- Lower 16-/32-bit access possible
- Little endian (internally big endian)
- L4 interconnect support

NOTE: Other information about Memory Stick PRO host controller are not available in the public domain.

MMC/SD/SDIO Card Interface

This chapter describes the features and functions of the multimedia card/SD/SD I/O (MMC/SDIO) card interface.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

24.6 MMC/SD/SDIO Use Cases and Tips	3426
24.7 MMC/SD/SDIO Register Manual	3438

24.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SD I/O (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are three MMC/SD/SDIO host controllers inside the device: [Figure 24-1](#) gives an overview of the MMC/SD/SDIO controller instances 1 and 3, and [Figure 24-2](#) gives an overview of the MMC/SD/SDIO2 controller instance.

Figure 24-1. MMC/SD/SDIO1 and 3 Overview

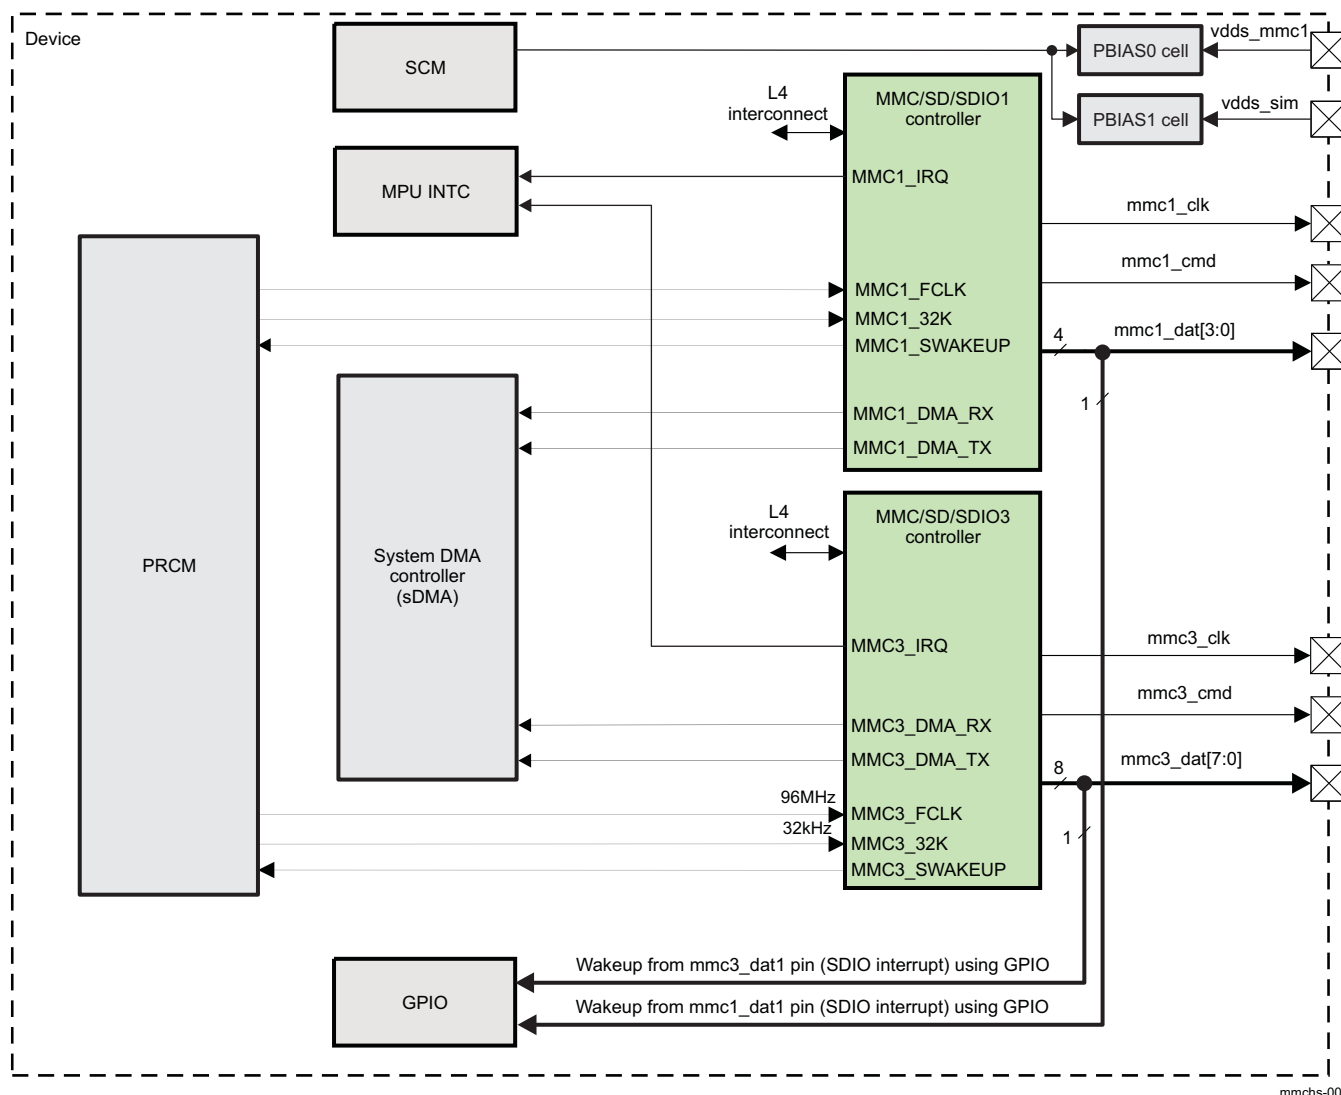

Figure 24-2. MMC/SD/SDIO2 Overview

24.1.1 MMC/SD/SDIO Features

The main features of the MMC/SD/SDIO host controller are:

- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification*, v4.2 including high-capacity (size > 2GB) cards HC MMC.
- Full compliance with SD command/response sets as defined in the *SD Memory Card Specifications*, v2.0 including high-capacity SDHC cards up to 32GB.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.2
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Flexible architecture allowing support for new command structure
- Support:
 - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
 - 1-bit, 4-bit, or 8-bit transfer mode specifications for MMC cards (1-bit and 4-bit only available for instance 1)
- Built-in 1024-byte buffer for read or write
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for multiple interrupt source events
- Two slave DMA channels (1 for TX, 1 for RX)

- Designed for low power
- Programmable clock generation
- Support SDIO Read Wait and Suspend/Resume functions
- Support Stop at block gap
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

The known limitations are as follows:

- No built-in hardware support for error correction codes (ECC). See the *Multimedia Card System Specification*, v4.2, and the *SD Memory Card Specifications*, v2.0, for details about ECC.
- The maximum block size defined in the *SD Memory Card Specifications*, v2.0, that the host driver can read and write to the buffer in the host controller is 2048 bytes. MMC supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in MMC is considered as a double buffering with ping-pong management; half of the buffer can be written while the other part is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

NOTE: MMC/e.MMC compliancy versus the *Multimedia Card System Specification*, v4.3 (or v4.4):

Full compliance with the MMC command/response sets and MMC bus testing procedure, as defined in the *Multimedia Card System Specification*, v4.2, does not prevent the use of e.MMC version 4.3 (or 4.4) devices with the OMAP36xx, because e.MMC devices are backward compatible. Only the e.MMC version 4.3 (or 4.4) boot operation is not supported in the OMAP36xx. Boot operation in the OMAP36xx follows the TI booting scheme, ID booting from standard memory array.

The differences between the MMC/SD/SDIO host controllers and a standard SD host controller are defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, as follows:

- The MMC/SD/SDIO host controllers support MMC cards.
- The MMC/SD/SDIO host controller is defined as a DMA slave device. A standard SD host controller is defined as a DMA master controller that can start and stop a DMA transfer. MMC/SD/SDIO host controllers support DMA transfers through slave DMA requests.
- The clock divider in MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v2.0. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy time-out.

24.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

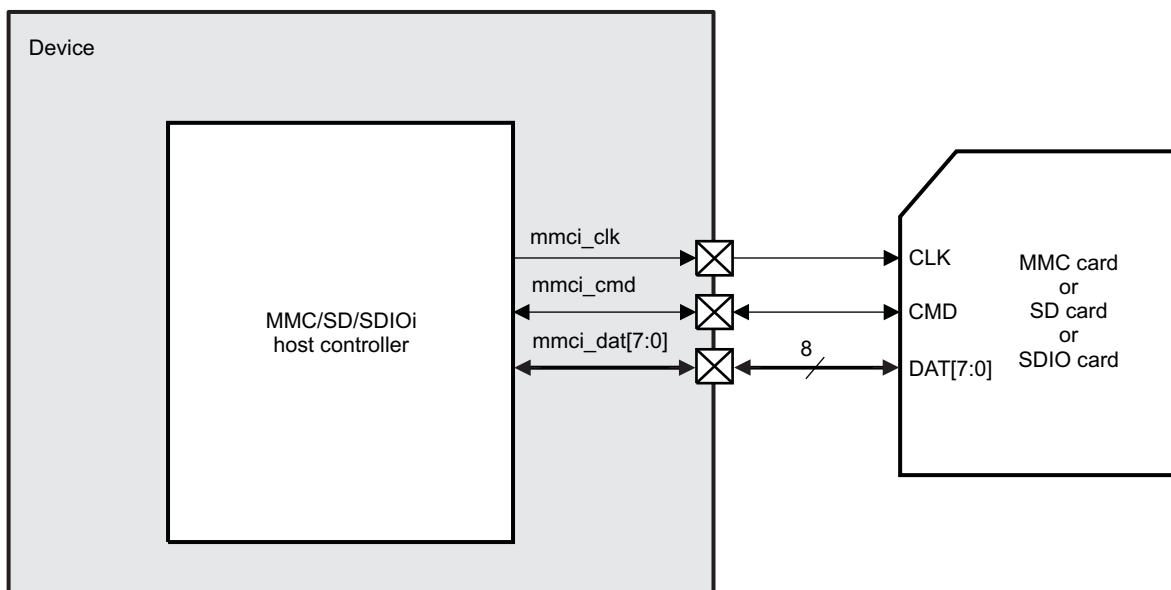

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The first controller (MMC/SD/SDIO1) integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 and 3V), without external transceiver. It supports 1-bit and 4-bit data transfer modes.
- The second controller (MMC/SD/SDIO2) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (WLAN device for example). The second instance also supports an external transceiver and provides direction signals for data and command. It supports 1-bit, 4-bit and 8-bit data transfer modes. Using an external transceiver device precludes 8-bit transfer mode.
- The third controller (MMC/SD/SDIO3) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (Wireless USB card for example). This interface is used without external transceiver. It supports 1-bit, 4-bit and 8-bit data transfer modes.

24.2.1 MMC/SD/SDIO Connected to MMC, SD, or SDIO Card

Figure 24-3 shows MMC/SD/SDIO_i host controller, instance 1, 2 or 3, connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 24-3. MMC/SD/SDIO Connected to MMC, SD, or SDIO Card Without External Transceiver

mmchs-002

24.2.2 MMC/SD/SDIO Connected to MMC, SD, or SDIO Card Through an External Transceiver Device

This connection is supported only by the MMC/SD/SDIO2 host controller. Figure 24-4 shows the MMC/SD/SDIO2 host controller connected to an MMC, an SD, or an SDIO card through an external transceiver device.

Figure 24-4. MMC/SD/SDIO2 Connected to MMC, SD, SDIO Card with External Transceiver

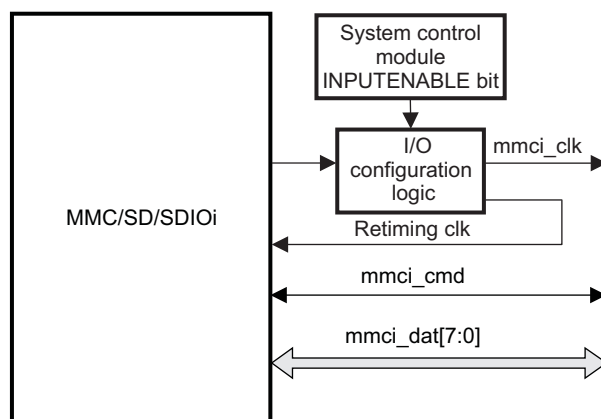

mmchs-003

24.2.3 MMC/SD/SDIO Functional Interfaces

24.2.3.1 Basic MMC/SD/SDIOi Pins Without External Transceiver

Figure 24-5 shows the MMC/SD/SDIOi host controller interface signals (instance 1, 2 or 3).

Figure 24-5. MMC/SD/SDIOi Interface Signals

mmchs-004

Table 24-1 describes the MMC/SD/SDIOi inputs/outputs.

Table 24-1. MMC/SD/SDIOi I/O Description

Signal Name	I/O ⁽¹⁾	Description	Reset Value
mmci_clk	O	External clock for MMC/SD/SDIO card ⁽²⁾	0
mmci_cmd	I/O	Command signal	0
mmci_dat[3:0]	I/O	Data signals	0

⁽¹⁾ I = Input; O = Output

⁽²⁾ This output signal is also used as retiming input (the CONTROL_PADCONF_x.INPUTENABLE bit must be set to 1).

Table 24-1. MMC/SD/SDIOi I/O Description (continued)

Signal Name	I/O ⁽¹⁾	Description	Reset Value
mmci_dat[7:4]	I/O	Data signals (only for instance 2 and 3)	0

24.2.3.2 Basic MMC/SD/SDIO2 Pins With External Transceiver

Figure 24-6 shows the MMC/SD/SDIO2 host controller interface signals.

Figure 24-6. MMC/SD/SDIO2 Interface Signals

Table 24-2 describes the MMC/SD/SDIO2 inputs/outputs.

Table 24-2. MMC/SD/SDIO2 I/O Description

Signal Name	I/O	Description	Reset Value
mmc2_clk	O	External clock for MMC/SD/SDIO card	0
mmc2_clkin	I	Input clock from MMC/SD/SDIO card	0
mmc2_cmd	I/O	Command signal	0
mmc2_dir_cmd	O	Direction control for mmc2_cmd signal case an external transceiver is used (high when transmit, low when receive)	0
mmc2_dat[3:0]	I/O	Data signals	0
mmc2_dir_dat0	O	Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat1	O	Direction control for mmc2_dat1 and mmc2_dat3 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat2	O	Direction control for mmc2_dat2 signal when an external transceiver is used (high when transmit, low when receive)	0
mmc2_dir_dat3	O	Direction control for mmc2_dat[7:4] signal when an external transceiver is used (high when transmit, low when receive). Unusable on the device because mmci_dat[7:4] are muxed with other direction control signals. See Chapter 13, System Control Module for further details on the pin multiplexing.	0

24.2.3.3 MMC/SD/SDIO Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

Command: a command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the mmci_cmd line.

Response: a response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmci_cmd line.

Data: data are transferred from the MMC/SD/SDIO host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: the mmci_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the mmci_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmci_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmci_dat0 and starts the data programming procedure.

24.2.3.3.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

See the *Multimedia Card System Specification, v4.2*, the *SD Memory Card Specifications, v2.0*, and the *SDIO Card Specification, Part E1*, August 2004, for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

Figure 24-7 and Figure 24-8 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

CAUTION
Stream commands are supported only by MMC cards.

Figure 24-7. Sequential Read Operation (MMC Cards Only)

Figure 24-8. Sequential Write Operation (MMC Cards Only)

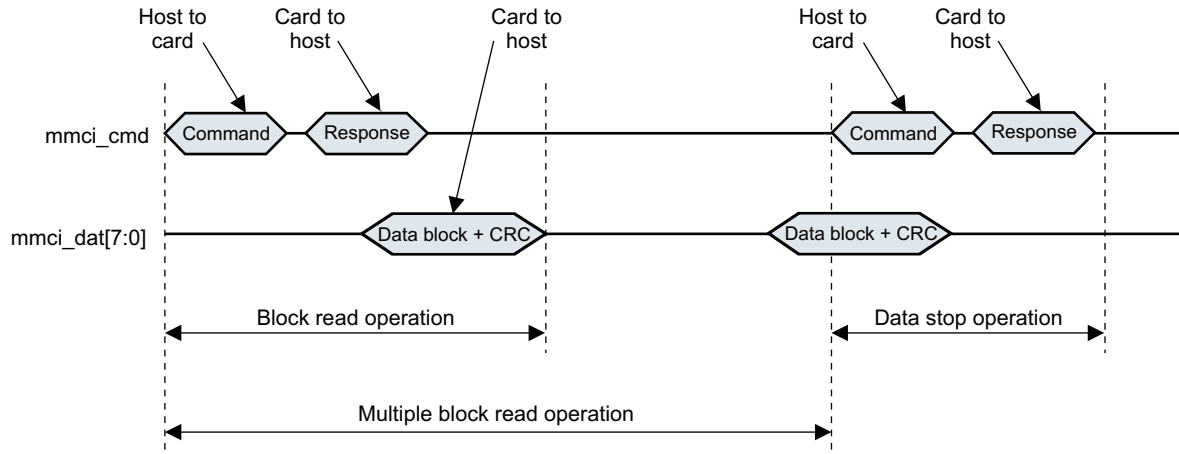

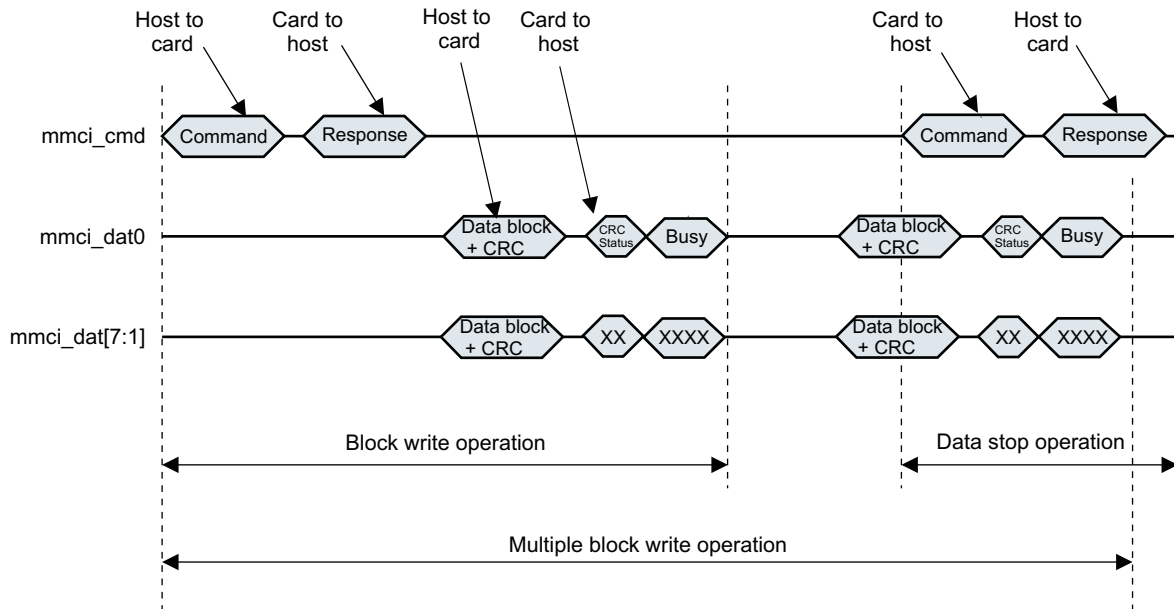

Figure 24-9 and Figure 24-10 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

Figure 24-9. Multiple Block Read Operation

mmchs-008

Figure 24-10. Multiple Block Write Operation with Card Busy Signal

mmchs-009

NOTE:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is software responsibility to do a software reset (set MMCI_MMCHS_SYSCTL[26] SRD bit to 0x1) after data timeout to ensure mmci_clk is stopped
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a CMD23 before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

24.2.3.3.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 24-11](#)).

Figure 24-11. Command Token Format

Coding Scheme for Response Token

Response tokens always start with 0 and end with a 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5 R6 [for SDIO]) and the content is protected by 7-bit CRC checksum (see [Figure 24-12](#) and [Figure 24-13](#)). Depending on the type of commands sent to the card, the `MMCHS_CMD` register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 24-3](#)). For more details about response types, see the *Multimedia Card System Specification, v4.2*, the *SD Memory Card Specifications, v2.0*, or the *SDIO Card Specification, Part E1, v1.10*.

Figure 24-12. Response Token Format (R1, R3, R4, R5, R6)

Figure 24-13. Response Token Format (R2)

Table 24-3. Relation Between Configuration and Name of Response Type⁽¹⁾

Response Type MMCI.MMCHS_CMD[17:16] RSP_TYPE	Index Check Enable MMCI.MMCHS_CMD[20] CICE	CRC Check Enable MMCI.MMCHS_CMD[19] CCCE	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3 (R4 for SD cards)
10	1	1	R1, R6, R5
11	1	1	R1b, R5b

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 24-14, Figure 24-15, and Figure 24-16).

24.3 MMC/SD/SDIO Integration

Figure 24-17 shows the internal connections between the three instances of the MMC/SD/SDIO host controller and the other modules

Figure 24-17. MMC/SD/SDIO1 Integration

mmchs-016

24.3.1 Clocking, Reset, and Power-Management Scheme

24.3.1.1 Clocks

24.3.1.1.1 Module Clocks

The MMC/SD/SDIO receives three clocks:

- A fixed functional clock of 96 MHz (the MMCi_FCLK) independent of the device external clock frequency
- An interface clock (the MMCi_ICLK) for interfacing with L4 interconnects (register accesses)
- A debounce clock, the MMCi_32K for reset process only

All these clocks are generated and controlled by the power, reset, and clock manager (PRCM) module (see [Chapter 3, Power, Reset, and Clock Management](#) for more information).

24.3.1.1.2 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (1 = 1 for MMC/SD/SDIO1, 2 for MMC/SD/SDIO2 and 3 for MMC/SD/SDIO3 instances).
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state (MMCI_ICLK clock autogated) even if MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCI_ICLK and MMCI_FCLK clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCI_ICLK and MMCI_FCLK clocks may be switched off whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY field.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

During normal to idle mode transition, any access to the registers of the MMC/SD/SDIOi host controller generates an error as long as the MMCI_ICLK clock is alive. The PRCM.CM_IDLEST1_CORE[25] ST_MMC2 and (respectively the PRCM.CM_IDLEST1_CORE[24] ST_MMC1 bit) is set to 0x0 when the MMC/SD/SDIO2 module (respectively the MMC/SD/SDIO1 module) can be accessed.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on mmci_dat[1] signal.

As long as the MMC/SD/SDIOi controller do not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM, the module does not assert any new interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- MMCI.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1
- MMCI.MMCHS_HCTL[24] IWE bit is set to 0x1
- MMCI.MMCHS_IE[8] CIRQ_ENABLE bit is set to 0x1

The wakeup is generated only in smart-idle mode only, when module is in idle mode.

Table 24-4 lists the supported cases in smart-idle mode.

Table 24-4. Smart Idle Mode and Wake-Up Capabilities

Mode	MMCI_ICLK clock	MMCI_FCLK clock	Wake-up Event
Card interrupt	May be switched off ⁽¹⁾	May be switched off ⁽¹⁾	The module sends an asynchronous wake-up request on detection of a card interrupt on mmci_dat[1] signal

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Transition From Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCI.MMCHS_STAT register. The MMC/SD/SDIOi host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the MMCI.MMCHS_ISE register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the MMCI.MMCHS_HCTL and MMCI.MMCHS_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCI.MMCHS_STAT is updated with the event that caused the wake-up in the CIRQ bit when the MMCI.MMCHS_IE[8] CIRQ_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCI.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode where the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCI.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCI_ICLK and MMCI_FCLK can be switched off.

CAUTION

In force-idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result.

When the module is idle, any access to the module generates an error as long as the MMCI_ICLK clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

24.3.1.2 Resets

24.3.1.2.1 Hardware Reset

The module is reinitialized by the hardware when the active-low reset signal (CORE_RST), synchronous to the MMCI_ICLK clock is asserted on the input pin MMCI_RESET (see [Chapter 3, Power, Reset, and Clock Management](#) for more information).

A global status bit RESETDONE is provided in the status register MMCI.MMCHS_SYSSTATUS[0]. This bit is set to 1 when all the different clock domain resets (interface domain, functional domain, and 32K domain) have been released.

The MMCI.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

NOTE: Functional clock MMCI_FCLK, interface clock MMCI_ICLK, and debounce clock MMCI_32K must be provided to the module to allow the RESETDONE status bit to be set.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

24.3.1.2.2 Software Reset

The module is reinitialized by software through the MMCI.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware MMCI_RESET signal except for:

- Debounce logic
- MMCI.MMCHS_PSTATE, MMCI.MMCHS_CAPA, and MMCI.MMCHS_CUR_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCI.MMCHS_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The MMCI.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCI.MMCHS_SYSCTL[26] SRD bit
- MMCI.MMCHS_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCI.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines and status management that

handle data transfers on both the interface and functional side.

- The MMCI.MMCHS_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

24.3.1.3 Power Domain

MMC/SD/SDIOi power is supplied by the CORE power domain (see [Chapter 3, Power Reset and Clock Management](#) for more information).

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor mmci_dat[1] input pin state via a different GPIO line for each MMC/SD/SDIO interface (see [Chapter 25, General-Purpose Interface](#), for more information).

24.3.2 Hardware Requests

24.3.2.1 DMA Requests

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification, Part A2, SD Host Controller Standard Specification, v1.00*.

The DMA request is issued if the three following conditions are met:

- The MMCI.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the mmci_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

DMA request lines are connected on the system DMA (sDMA) inputs:

- S_DMA_60 (MMC1_DMA_TX)
- S_DMA_61 (MMC1_DMA_RX)
- S_DMA_46 (MMC2_DMA_TX)
- S_DMA_47 (MMC2_DMA_RX)
- S_DMA_76 (MMC3_DMA_TX)
- S_DMA_77 (MMC3_DMA_RX)

24.3.2.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCI_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCI.MMCHS_BLK[10:0] BLEN field.

The MMCI_DMA_RX signal is deasserted to its inactive level when the sDMA has read one single word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

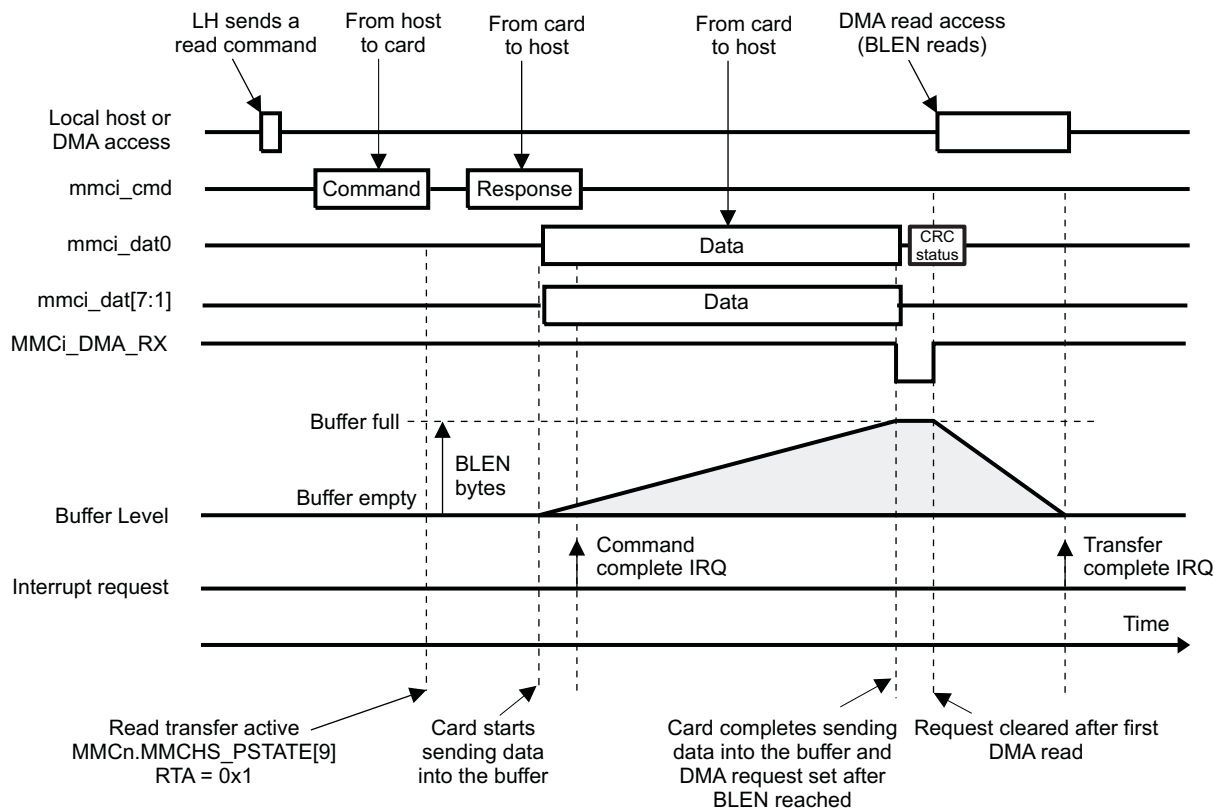

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the mmci_clk clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Summary (see [Figure 24-18](#)):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst

- One DMA request per block

Figure 24-18. DMA Receive Mode

mmchs-018

24.3.2.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal `MMCi_DMA_TX` is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` BLEN field.

The `MMCi_DMA_TX` signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

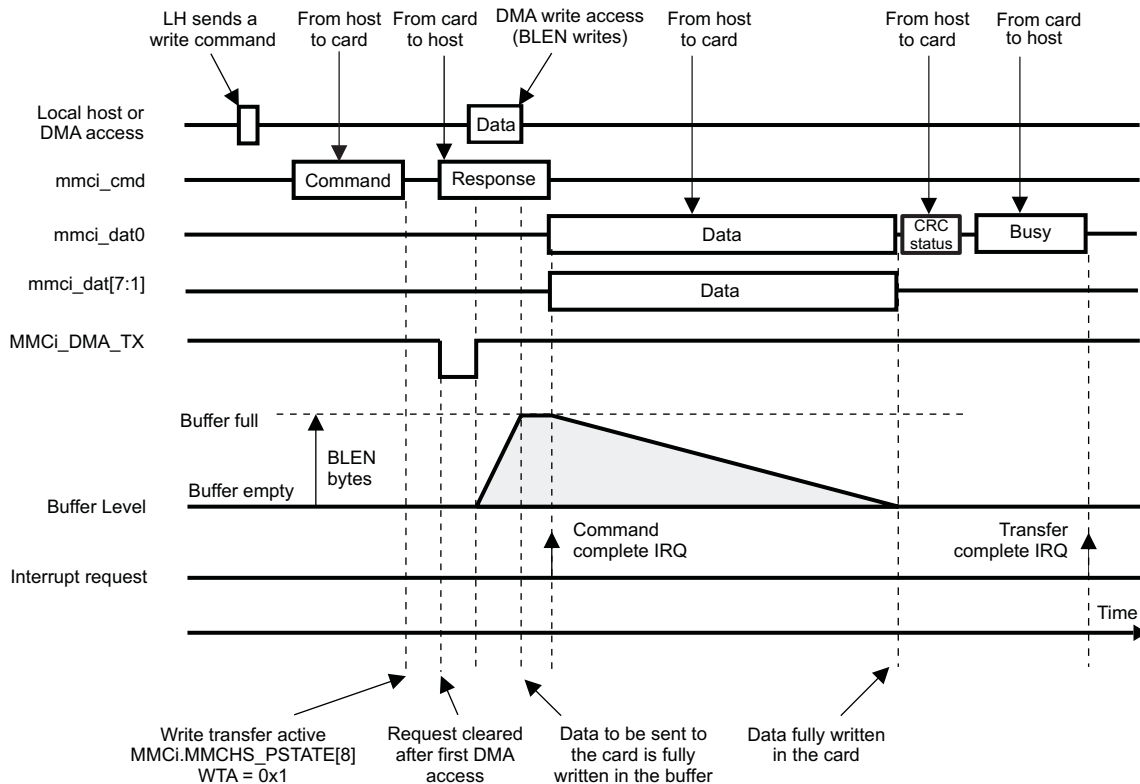

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$) and if there is not enough memory space to write a complete block in the buffer.

Summary (see [Figure 24-19](#)):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 24-19. DMA Transmit Mode

mmchs-019

24.3.2.2 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the MMCi.MMCHS_STAT register; it indicates which service is required.
- The interrupt status enable bits of the MMCi.MMCHS_IE register enable/disable the automatic update of the MMCi.MMCHS_STAT register on an event-by-event basis.
- The interrupt signal enable bits of the MMCi.MMCHS_ISE register enable/disable the transmission of an interrupt request on the interrupt line MMCi_IRQ (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the MMCi.MMCHS_IE register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the MMCi.MMCHS_ISE register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the MMCi.MMCHS_STAT register. If later a mask is applied on the interrupt in the MMCi.MMCHS_ISE register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the MMCi.MMCHS_STAT register and the corresponding mask is removed from the MMCi.MMCHS_ISE register, the interrupt status is not asserted again in the MMCi.MMCHS_STAT register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the MMCI.MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status MMCI.MMCHS_STAT or transmitting an interrupt request.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

There are one interrupt line for each instance of the MMC/SD/SDIOi host controller:

- MMC1_IRQ is connected to M_IRQ_83 for MMC/SD/SDIO1 instance.
- MMC2_IRQ is connected to M_IRQ_86 for MMC/SD/SDIO2 instance.
- MMC3_IRQ is connected to M_IRQ_94 for MMC/SD/SDIO3 instance.

24.3.2.2.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCI.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the MMCI.MMCHS_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the MMCI.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the MMCI.MMCHS_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.
The MMCI.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCI.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR). See [Chapter 9, Interconnect](#) for more information.
The MMCI.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in MMCI.MMCHS_STAT[31:16] are cleared.

24.3.2.2.2 Polling

When the interrupt capability of an event is disabled in the MMCI.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCI.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCI.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: See the previous note concerning CIRQ and ERRI bits clearing.

24.4 MMC/SD/SDIO Functional Description

24.4.1 Description

MMC/SD/SDIOi host controller is partitioned into two clock domains:

- The interface L4 clock domain
- The functional clock domain

Any two domains are considered asynchronous to each other, and exchanges between the two domains are synchronized through a synchronization stage and an asynchronous buffer. Data are transferred from one domain to other through the buffer (2*512 RAM).

[Figure 24-20](#) shows a block diagram of the MMC/SD/SDIO host controller.

Figure 24-20. MMC/SD/SDIO Diagram

mmchs-020

In the L4 clock domain, the user can:

- Control the transfer (configure parameters for the transfer)
- Control clock activities and reset
- Manage interrupts and hardware requests
- Consult different status:
 - Bus
 - Buffer
 - Interrupts
 - Errors
- Transmit and receive data through the buffer

In the functional clock domain, the internal mechanisms perform the transfers of data and commands.

For more detail see the command response registers (MMCi.MMCHS_RSPn registers: [Table 24-53](#), [Table 24-55](#), [Table 24-57](#), and [Table 24-59](#)).

CAUTION

Read access to the command response registers is allowed only when the command process is completed.

24.4.2 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes: MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, and the *SDIO Card Specification, Part E1*, v1.10, for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

24.4.3 Buffer Management

24.4.3.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer divided into two 512-byte portions that are 32 bits wide by 128 words deep. This buffer transfers data from one data bus (Interconnect) to another data bus (SD SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer for the two portions, the prefetch buffer and the post-write buffer, is the 32-bit register MMCI.MMCHS_DATA. A write access to the MMCI.MMCHS_DATA register followed by a read access from the MMCI.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCI.MMCHS_DATA register and the data of the read access to the MMCI.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCI.MMCHS_DATA register that are needed to read (or write) a data block with a size of MMCI.MMCHS_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is 1024 bytes. This value is hard-coded in the register MMCI.MMCHS_CAPA[17:16] MBL field and cannot be changed.

A read access to the MMCI.MMCHS_DATA register is allowed only when the buffer read enable status is set to 1 (MMCI.MMCHS_PSTATE[11] BRE); otherwise, a bad access (MMCI.MMCHS_STAT[29] BADA) is signaled.

A write access to the MMCI.MMCHS_DATA register is allowed only when the buffer write enable status is set to 1 (MMCI.MMCHS_PSTATE[10] BWE); otherwise, a bad access (MMCI.MMCHS_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to 512 bytes, meaning the value written in BLEN is less than or equal to 0x200, two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than, or equal to 0x200 (that is, less than, or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits x BLEN div by 4). Do not use a size greater than 2 times this value.

CAUTION

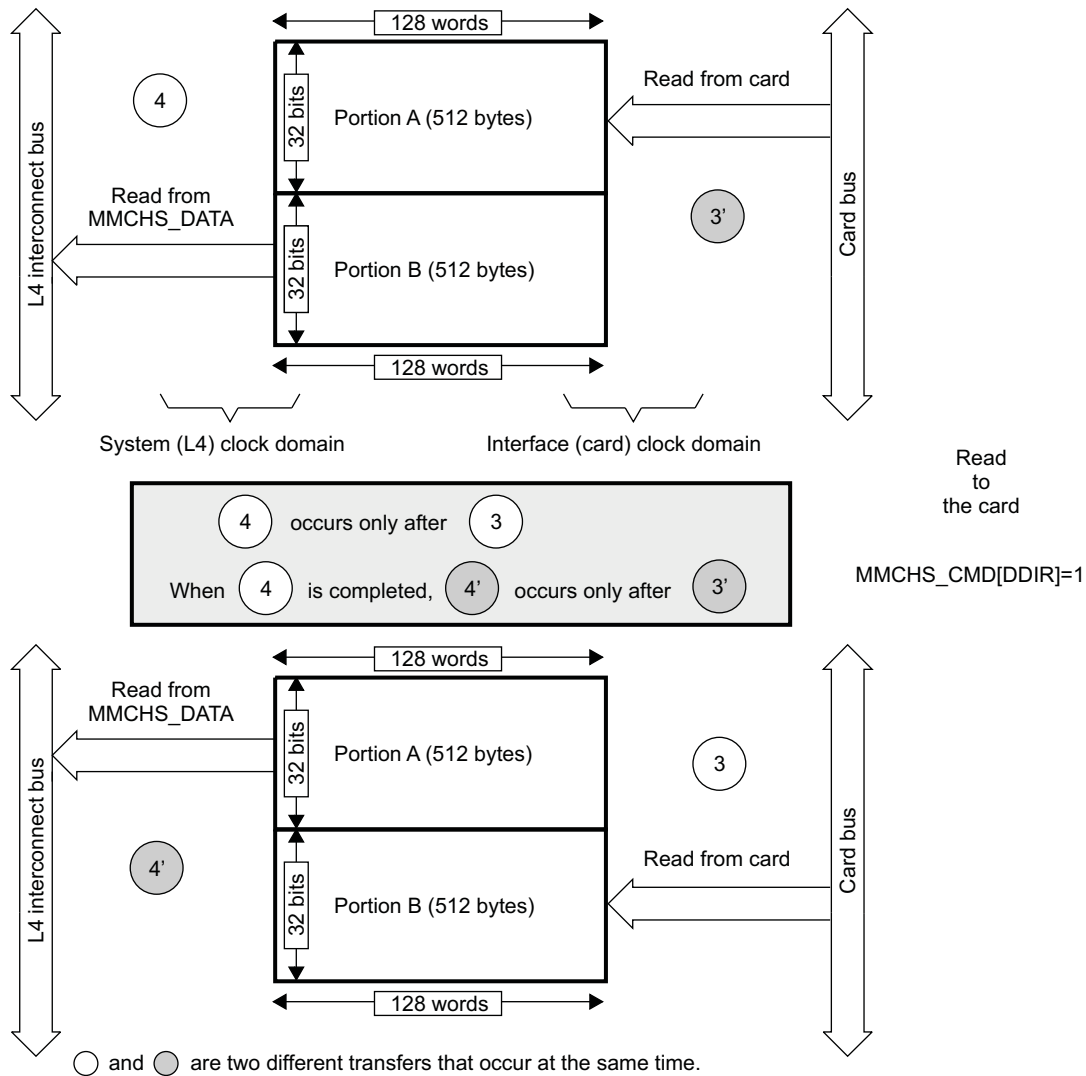

The MMCI.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 24-21 and Figure 24-22 show the buffer management for a write and for a read, respectively.

Figure 24-21. Buffer Management for a Write

mmchs-047

Figure 24-22. Buffer Management for a Read

- When the size of the data block to transfer is larger than 512 bytes, meaning the value written in BLEN is 0x201 or larger, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIOi host controller uses the entire data buffer as a single 1024-byte portion. In this mode, a bad access (MMCi.MMCHS_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

24.4.3.1.1 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see Table 24-69):
 - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
 - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
 - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers (see Table 24-63):
 - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
 - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

24.4.4 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

24.4.4.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

24.4.4.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

Table 24-5 shows how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 24-5. MMC, SD, SDIO responses in the MMCHS_RSPxx registers

Kind of Response	Response Field	Response Register
R1, R1b (normal response), R3, R4, R5, R5b, R6	RESP[39:8] ⁽¹⁾	MMCHS_RSP10[31:0]
R1b (Auto CMD12 response)	RESP[39:8] ⁽¹⁾	MMCHS_RSP76[31:0]
R2	RESP[127:0] ⁽¹⁾	MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0]

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in MMCHS_RSP10 register and vice versa.

24.4.5 Transfer or Command Status and Error Reporting

Flags in the MMC/SD/SDIOi host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 24-6 and register description for more details.

Table 24-6. CC and TC Values Upon Error Detected

Error hold in the MMCi.MMCHS_STAT register	CC	TC	Comments
29 BADA			No dependency with CC nor TC BADA is related to MMCHS_DATA register accesses. Its assertion is not dependent of the ongoing transfer.
28 CERR	1		CC is set upon CERR.
22 DEB		1	TC is set upon DEB.
21 DCRC		1	TC is set upon DCRC.
20 DTO			DTO and TC are mutually exclusive DCRC and DEB cannot occur with DTO.
19 CIE	1		CC is set upon CIE.

Table 24-6. CC and TC Values Upon Error Detected (continued)

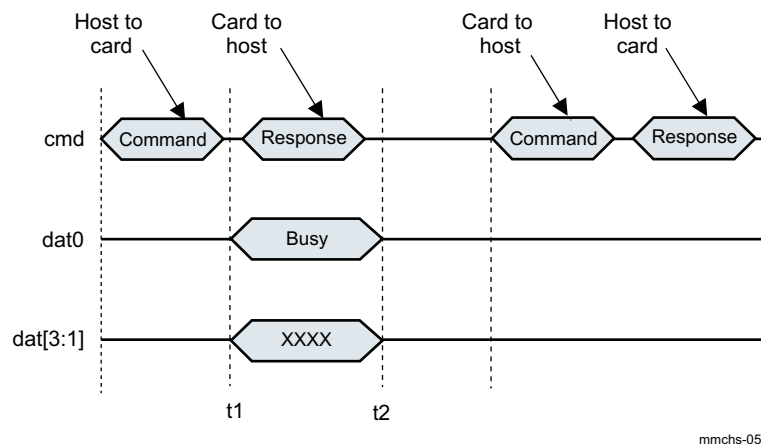

Error hold in the MMCi.MMCHS_STAT register	CC	TC	Comments
18 CEB	1		CC is set upon CEB.
17 CCRC	1		CC can be set upon CCRC - See CTO comment
16 CTO			CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: it indicates a command abort due to a contention on CMD line. In this case no CC appears.

MMCHS_STAT[21] DCRC event can be asserted in the following conditions:

- busy timeout for R1b, R5b response type
- busy timeout after write CRC status
- write CRC status timeout
- read data timeout
- boot acknowledge timeout

24.4.5.1 Busy Timeout For R1b, R5b Response Type

Figure 24-23 shows DCRC event condition asserted when there is busy timeout for Rb1, R5b response.

Figure 24-23. Busy Timout for R1b, R5b Response Type

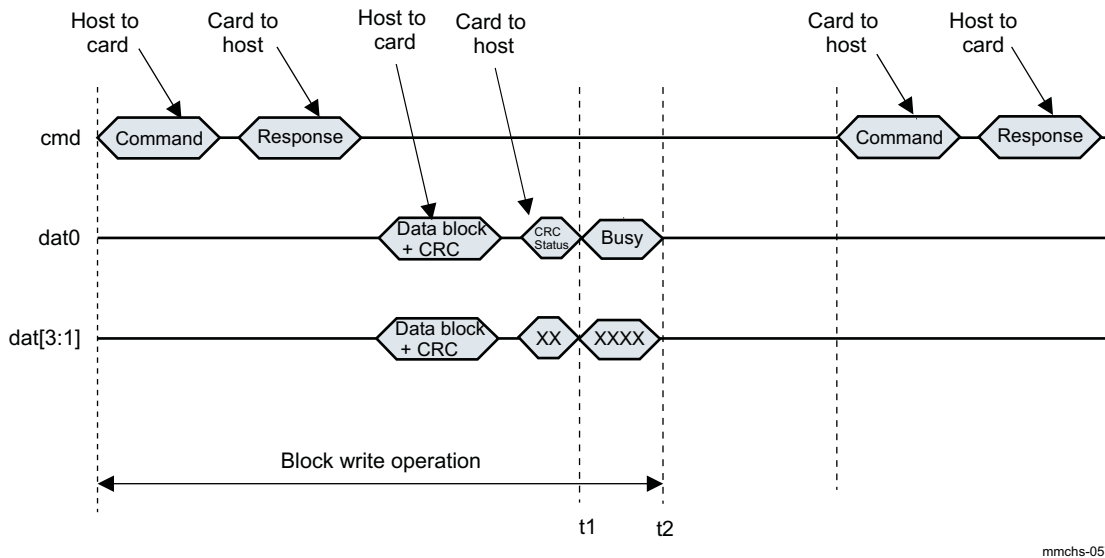

t1 - Data timeout counter is loaded and starts after R1b, R5b response type

t2 - Data timeout counter stops and if it is 0, MMCHS_STAT[21] DCRC is generated.

24.4.5.2 Busy Timeout After Write CRC Status

Figure 24-24 shows DCRC event condition asserted when there is busy timeout after write CRC status.

Figure 24-24. Busy Timeout After Write CRC Status

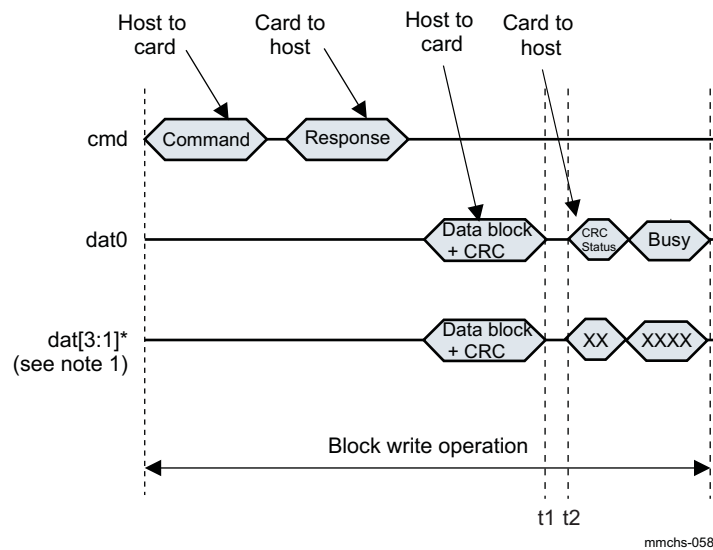

t1 - Data timeout counter is loaded and starts after CRC Status

t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

24.4.5.3 Write CRC Status Timeout

Figure 24-25 shows DCRC event condition asserted when there is write CRC status timeout.

Figure 24-25. Write CRC Status Timeout

t1 - Data timeout counter is loaded and starts after Data block + CRC

t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

24.4.5.4 Read Data Timeout

Figure 24-26 shows DCRC event condition asserted when there is read data timeout.

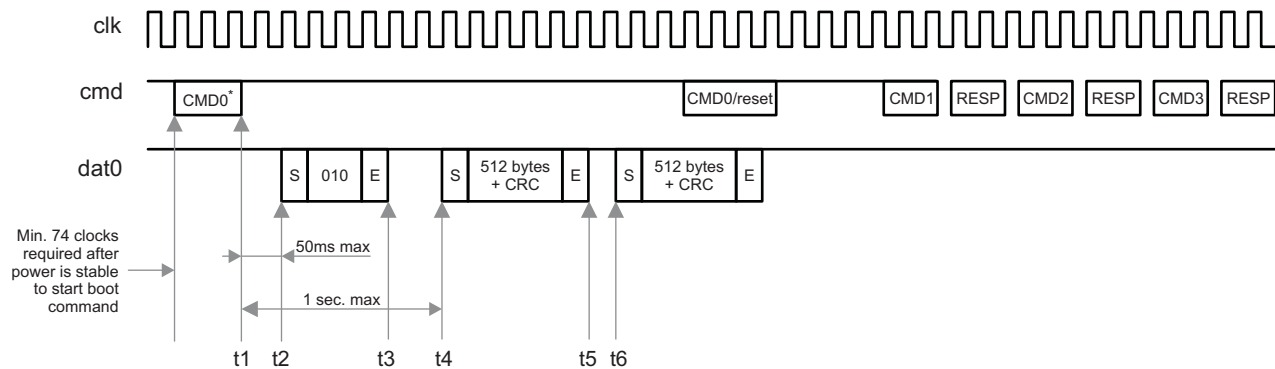

Figure 24-26. Read Data Timeout

mmchs-059

- t1 - Data timeout counter is loaded and starts after Command transmission.
- t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.
- t3 - Data timeout counter is loaded and starts after Data block + CRC transmission.
- t4 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

24.4.5.5 Boot Acknowledge Timeout

[Figure 24-28](#) shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

Figure 24-27. Boot Acknowledge Timeout When Using CMD0

* Refer to MMC specification for correct argument.

mmchs-060

- t1 - Data timeout counter is loaded and starts after CMD0.
- t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.
- t3 - Data timeout counter is loaded and starts.
- t4 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.
- t5 - Data timeout counter is loaded and starts after Data + CRC transmission.
- t6 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[21\]](#) DCRC is generated.

[Figure 24-28](#) shows DCRC event condition asserted when there is boot acknowledge timeout and CMD0 is used.

Figure 24-28. Boot Acknowledge Timeout When CMD Line Tied To 0

mmchs-061

- t1 - Data timeout counter is loaded and starts after cmd line is tied to 0.
- t2 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[DCRC\]](#) is generated.
- t3 - Data timeout counter is loaded and starts.
- t4 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[DCRC\]](#) is generated.
- t5 - Data timeout counter is loaded and starts after Data + CRC transmission.
- t6 - Data timeout counter stops and if it is 0, [MMCHS_STAT\[DCRC\]](#) is generated.

24.4.6 Autocommand 12 Timings

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, SD standard imposes a specific timing for Auto CMD12 'end bit' arrival.

24.4.6.1 Autocommand 12 Timings During Write Transfer

A margin named Nrc in range of 2 to 8 cycles has been defined for SDR50 and SDR104 card components for write data transfers, as autocommand 12 'end bit' shall arrive after the CRC status 'end bit'.

Figure 24-29 shows auto CMD12 timings during write transfer.

Figure 24-29. Autocommand 12 Timings During Write Transfer

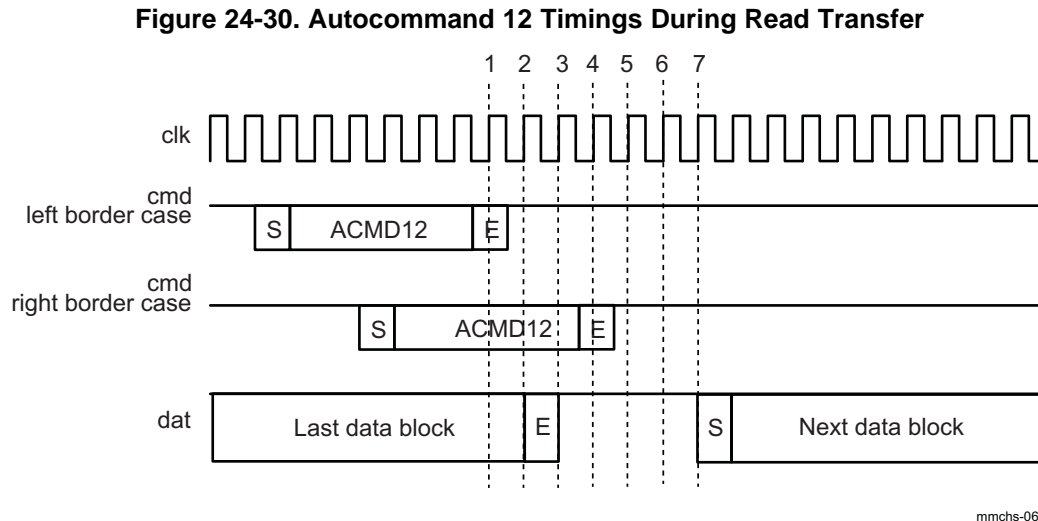

mmchs-062

The Host controller has a margin of 18 clock cycles to make sure that auto CMD12 'end bit' arrives after the CRC status. This margin does not depend on MMC bus configuration, DDR or standard transfer, 1, 4 or 8 bus width.

24.4.6.2 Autocommand 12 Timings During Read Transfer

With UHS very high speed cards gap timing between 2 successive cards has been extended to 4 cycles instead of 2. By the way it gives more flexibility for Host Auto CMD12 arrival in order to receive the last complete and reliable block. MMCHS controller only follows the 'Left Border Case' defined by SD UHS specification.

Figure 24-30 shows ACMD12 timings during read transfer.

The Auto CMD12 arrival sent by the Host controller is not sensitive to the MMC bus configuration whether it is DDR or standard transfer and whether it is a 1,4 or 8 bit bus width transfer.

24.4.7 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features which makes a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).

This feature is enabled by setting the MMCI.MMCHS_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIOi controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.

- Stop at block gap

This feature is enabled by setting the MMCI.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

NOTE: For MMC and SD cards, the stop at block gap feature is not supported in READ mode.

For SDIO cards, this setting can be supported in READ mode if the card has a read wait capability.

Table 24-7 shows the common way to stop a transfer, indicating command to send and features to enable.

Table 24-7. MMC/SD/SDIOi Controller Transfer Stop Command Summary

		WRITE transfer		READ transfer	
		SD / MMC	SDIO	SD / MMC	SDIO
Single block		Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC	Transfer ends automatically Wait TC
Multi blocks (finite or infinite)	Before the programmed block boundary	Send CMD12 Wait TC	Send CMD52 Wait TC	Send CMD12 Wait TC	Send CMD52 Wait TC
	Stop at the end of the transfer (finite transfer only)	Auto CMD12 active Transfer ends automatically Wait TC	Set MMCi.MMCHS_HC TL[16] SBGR bit to 0x1. Send CMD52 Wait TC	Auto CMD12 active Transfer ends automatically Wait TC	If READ_WAIT supported Stop at block gap Wait TC If READ_WAIT not supported Send CMD52 Wait TC

NOTE: The MMC/SD/SDIOi controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

24.4.8 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal ([MMCHS_CON\[12\]](#) CEATA and [MMCHS_CMD\[2\]](#) ACEN set to 1) is launched, host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable.

The settings to emit a command completion disable token follow:

- [MMCHS_CON\[12\]](#) CEATA is set to 1.
- [MMCHS_CON\[2\]](#) HR set to 1.
- Clear the [MMCHS_ARG](#) register.
- Write into [MMCHS_CMD](#) register with value 0x00000000.

When a command completion disable token was emitted (that is, [MMCHS_STAT\[0\]](#) CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

- CCS is receive just before CCSD is emitted:
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:
The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:

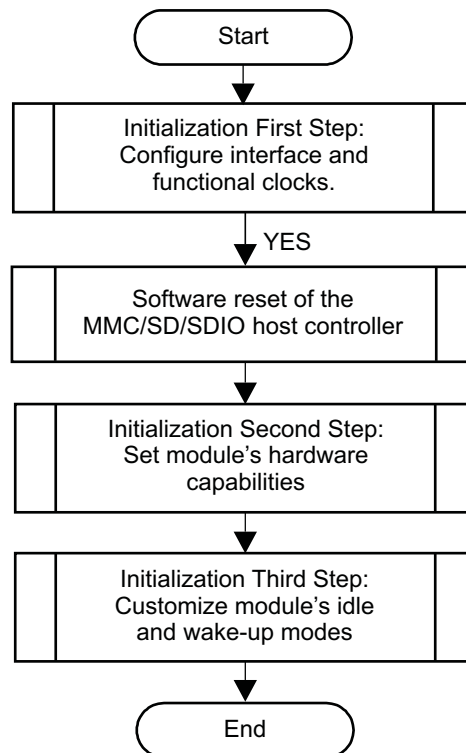

Only the interrupt CIRQ is generated when CCS is detected.

24.5 MMC/SD/SDIO Basic Programming Model

24.5.1 MMC/SD/SDIO Host Controller Initialization Flow

Figure 24-31 shows the general boot process.

Figure 24-31. MMC/SD/SDIO Controller Meta Initialization Steps

mmchs-024

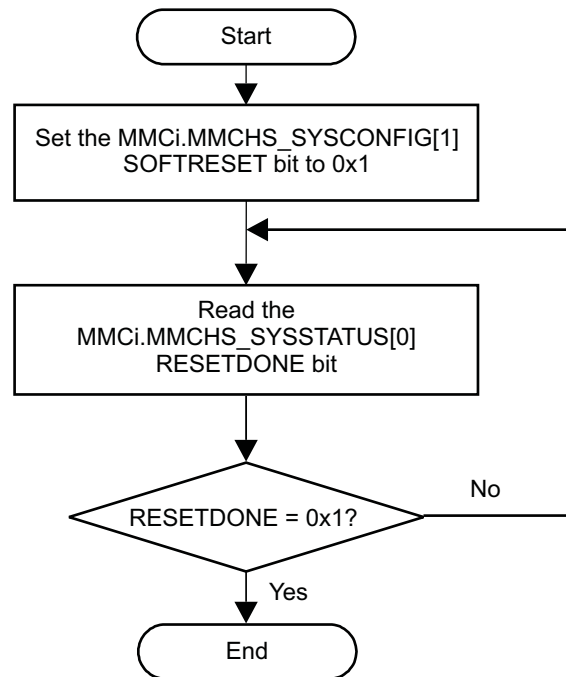

24.5.1.1 Enable Interface and Functional clock for MMC Controller

Prior to any MMCHS register access one must enable MMCHS interface clock and functional clock in PRCM module registers PRCM.CM_ICLKEN1_CORE and PRCM.CM_FCLKEN1_CORE. See [Chapter 3, Power, Reset, and Clock Management](#).

24.5.1.2 MMCHS Soft Reset Flow

Figure 24-32 shows the soft reset process of MMCHS controller.

Figure 24-32. MMC/SD/SDIO Controller Software Reset Flow

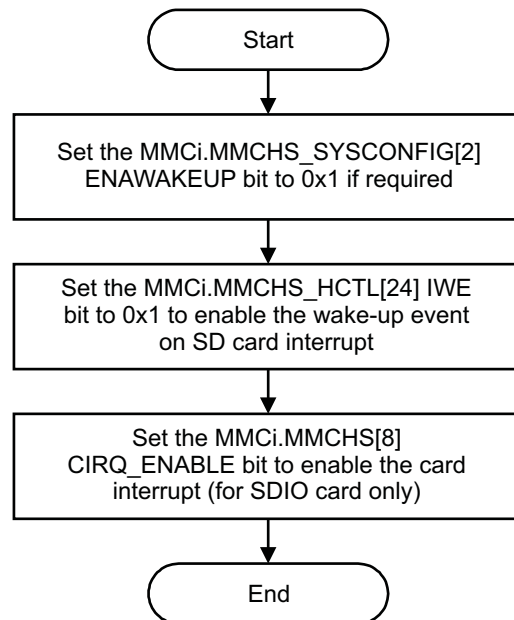

mmchs-025

24.5.1.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) `MMCi.MMCHS_CAPA[26:24]` and `MMCi.MMCHS_CUR_CAPA[23:0]` registers before the MMC/SD/SDIO host driver is started.

24.5.1.4 Wake-Up Configuration

Figure 24-33 details MMCHS controller wake-up configuration.

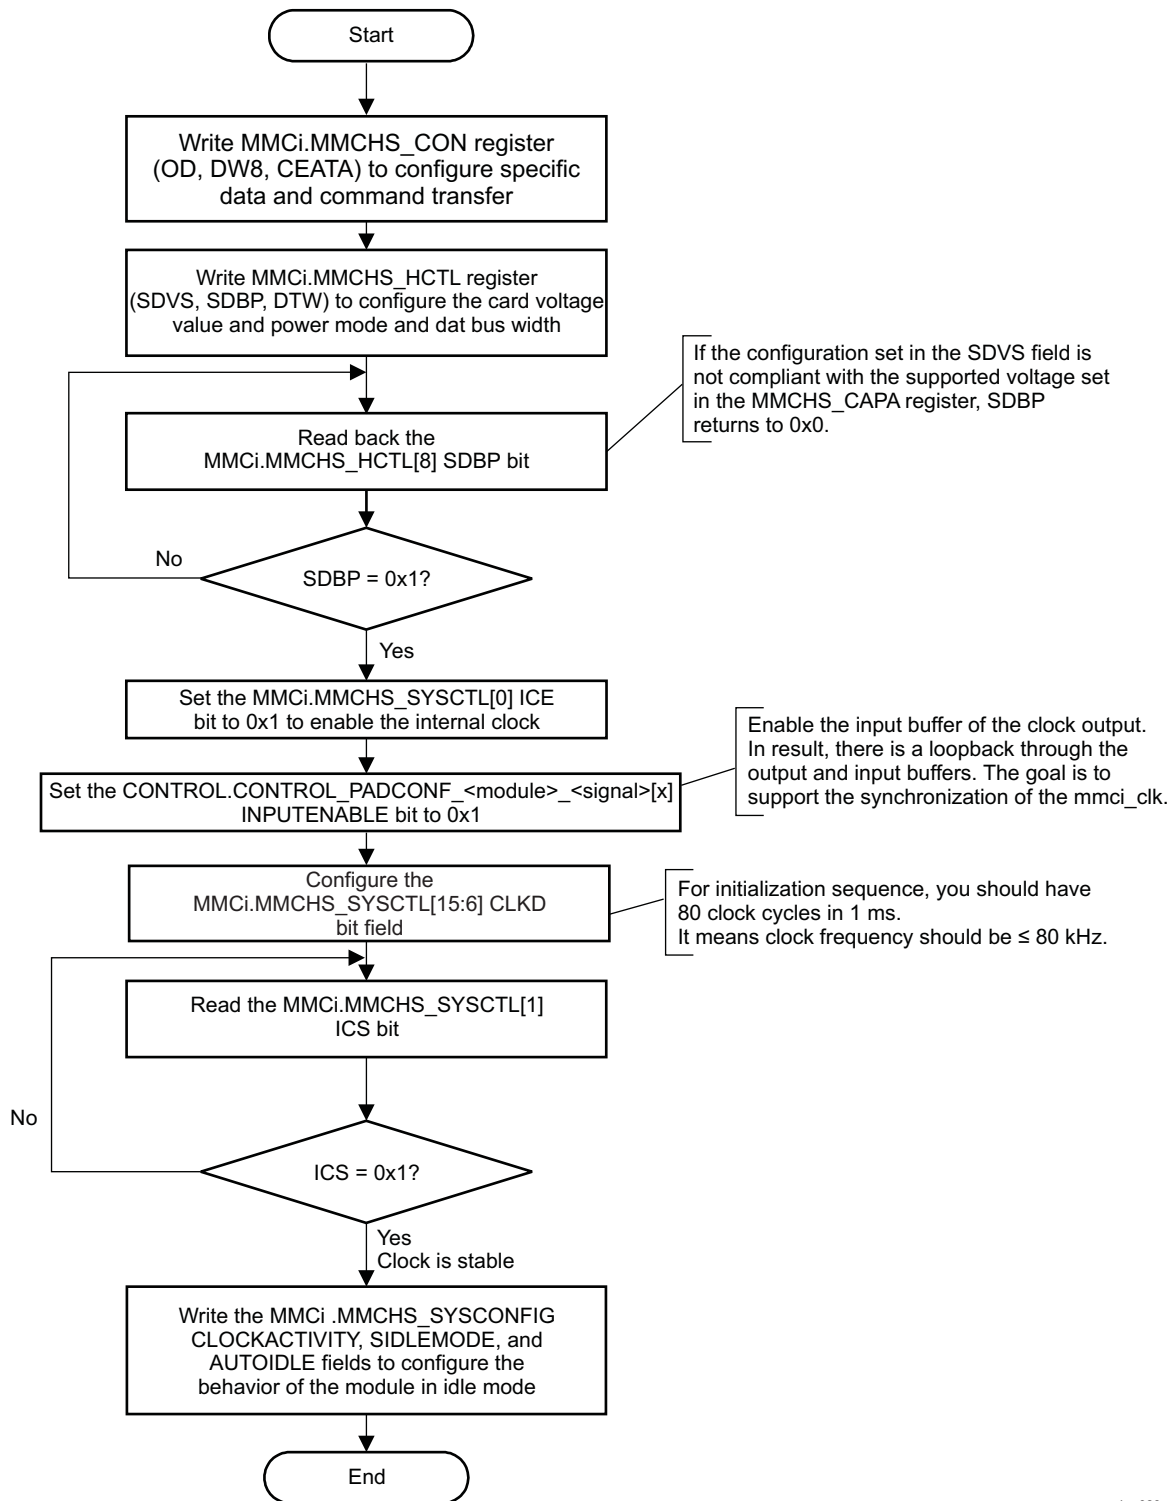

Figure 24-33. MMC/SD/SDIO Controller Wake-Up Configuration

mmchs-027

24.5.1.5 MMC Host and Bus Configuration

[Figure 24-34](#) details MMC bus configuration process.

Figure 24-34. MMC/SD/SDIO Controller Bus Configuration

24.5.2 Basic Operations for MMC/SD/SDIO Host Controller

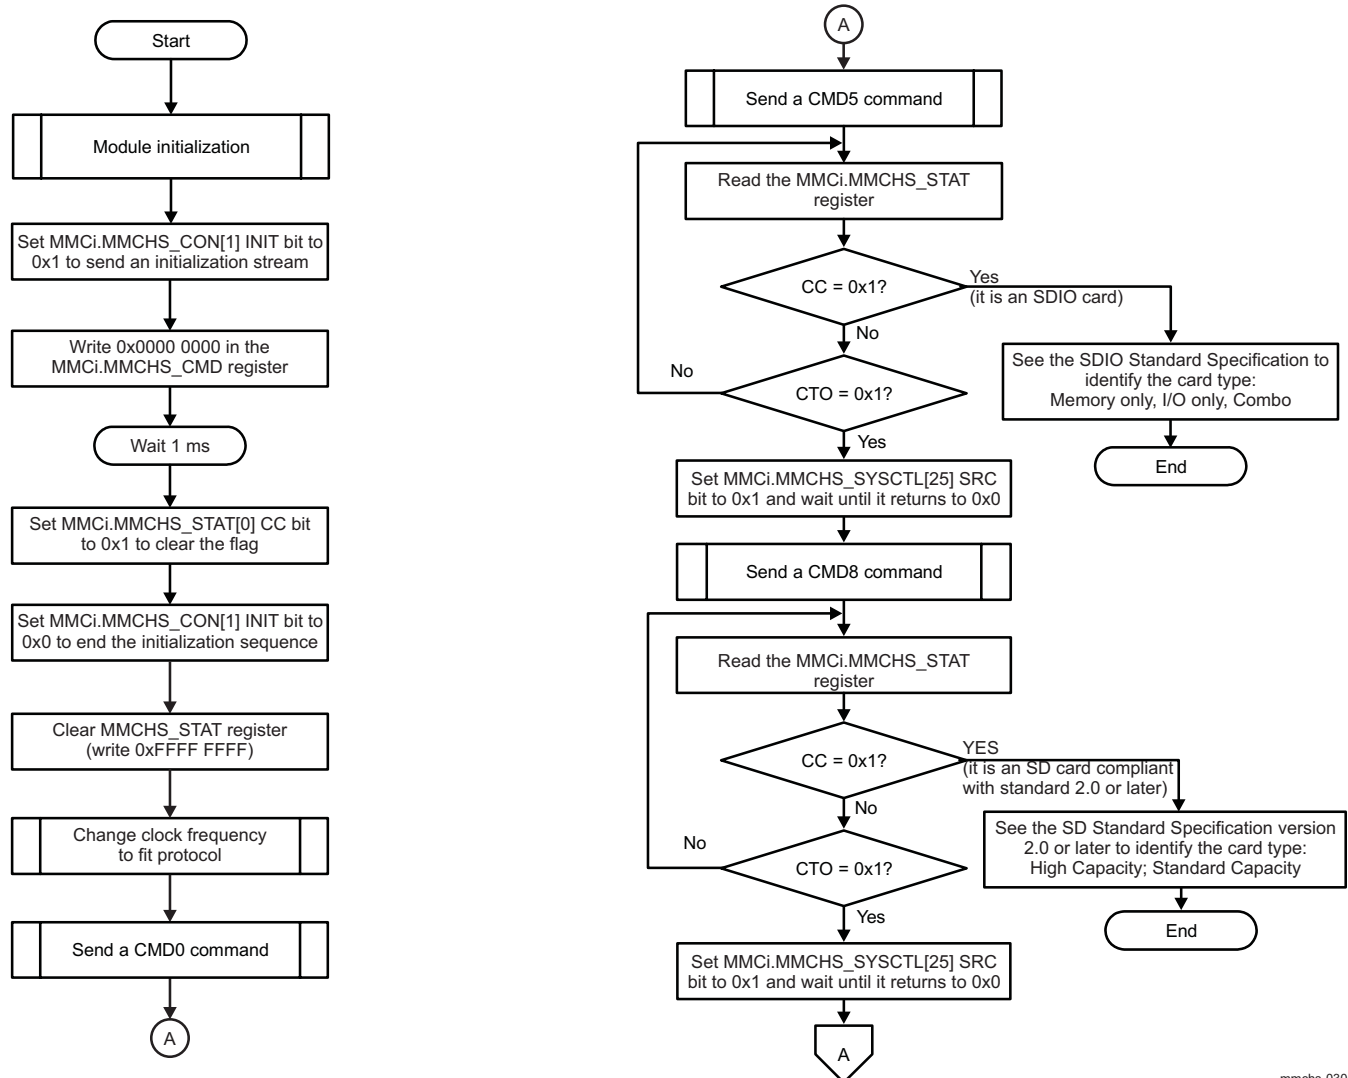

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

24.5.2.1 Card Detection, Identification, and Selection

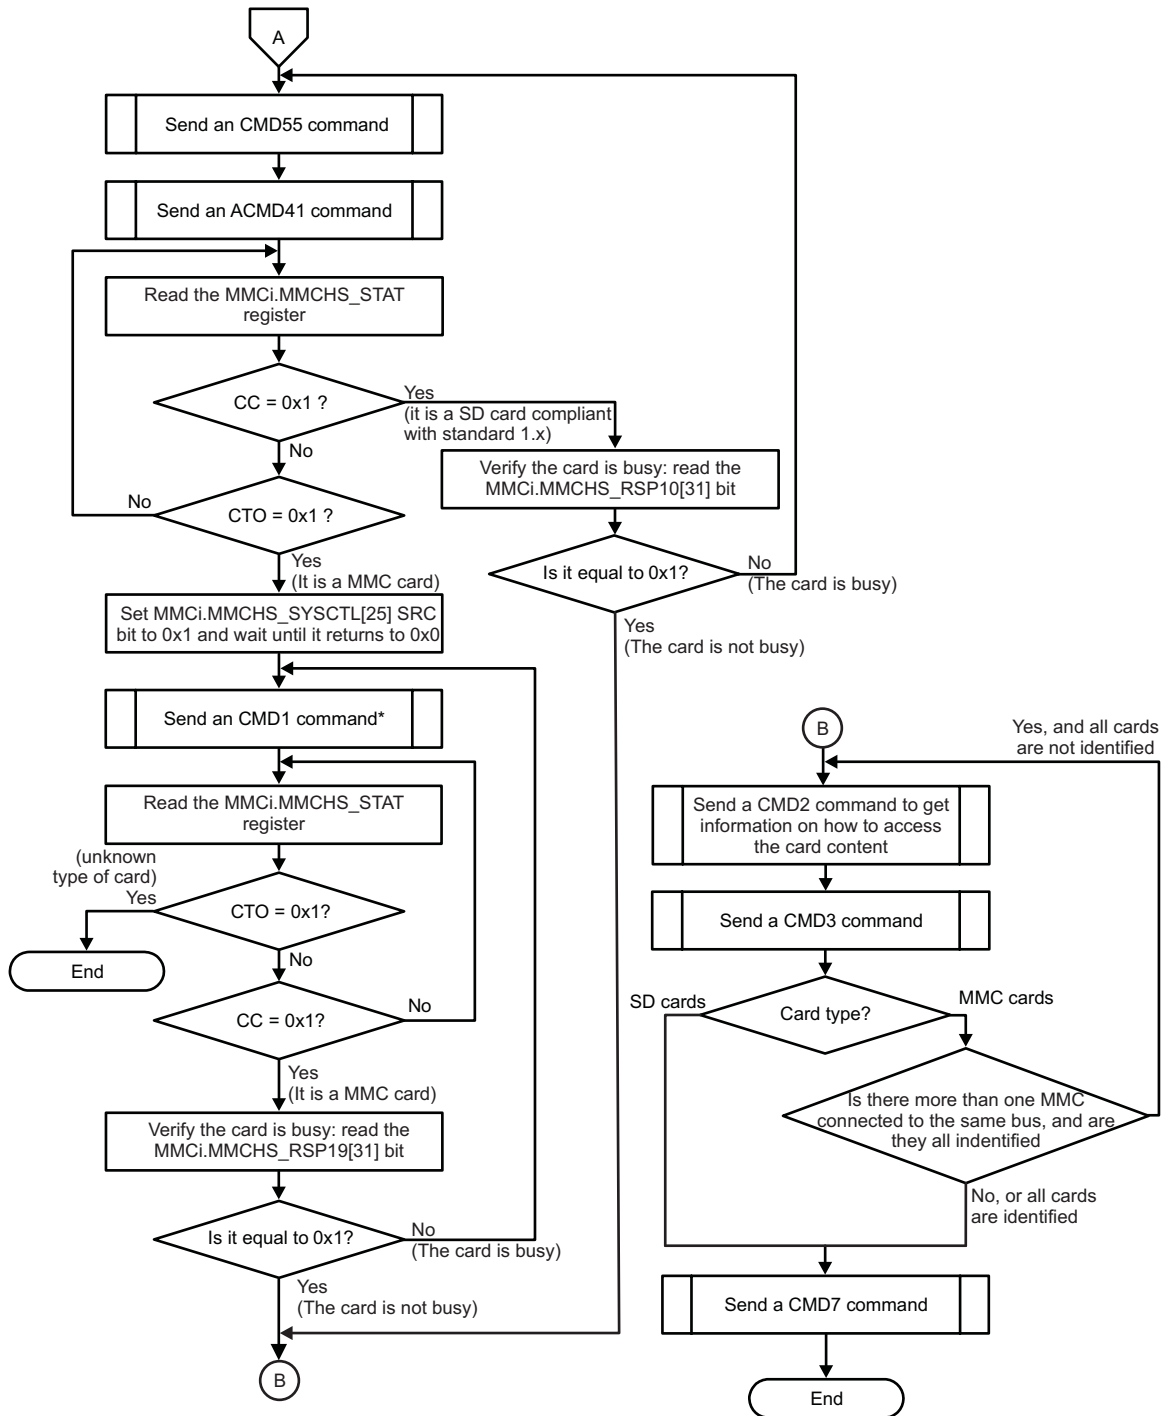

Figure 24-35 and Figure 24-36 show the card identification and selection process.

Figure 24-35. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

mmchs-030

Figure 24-36. MMC/SD/SDIO Controller Card Identification and Selection - Part 2

*With OCR 0. In case of a CMD1 with OCR=0, a second CMD1 must be sent to the card with the "negotiated" voltage.

24.5.2.2 Read/Write Transfer Flow in DMA Mode With Interrupt

Figure 24-37 describes the read and write protocol in DMA mode with interrupt signaling. See Chapter 11, SDMA, for more information on the DMA settings.

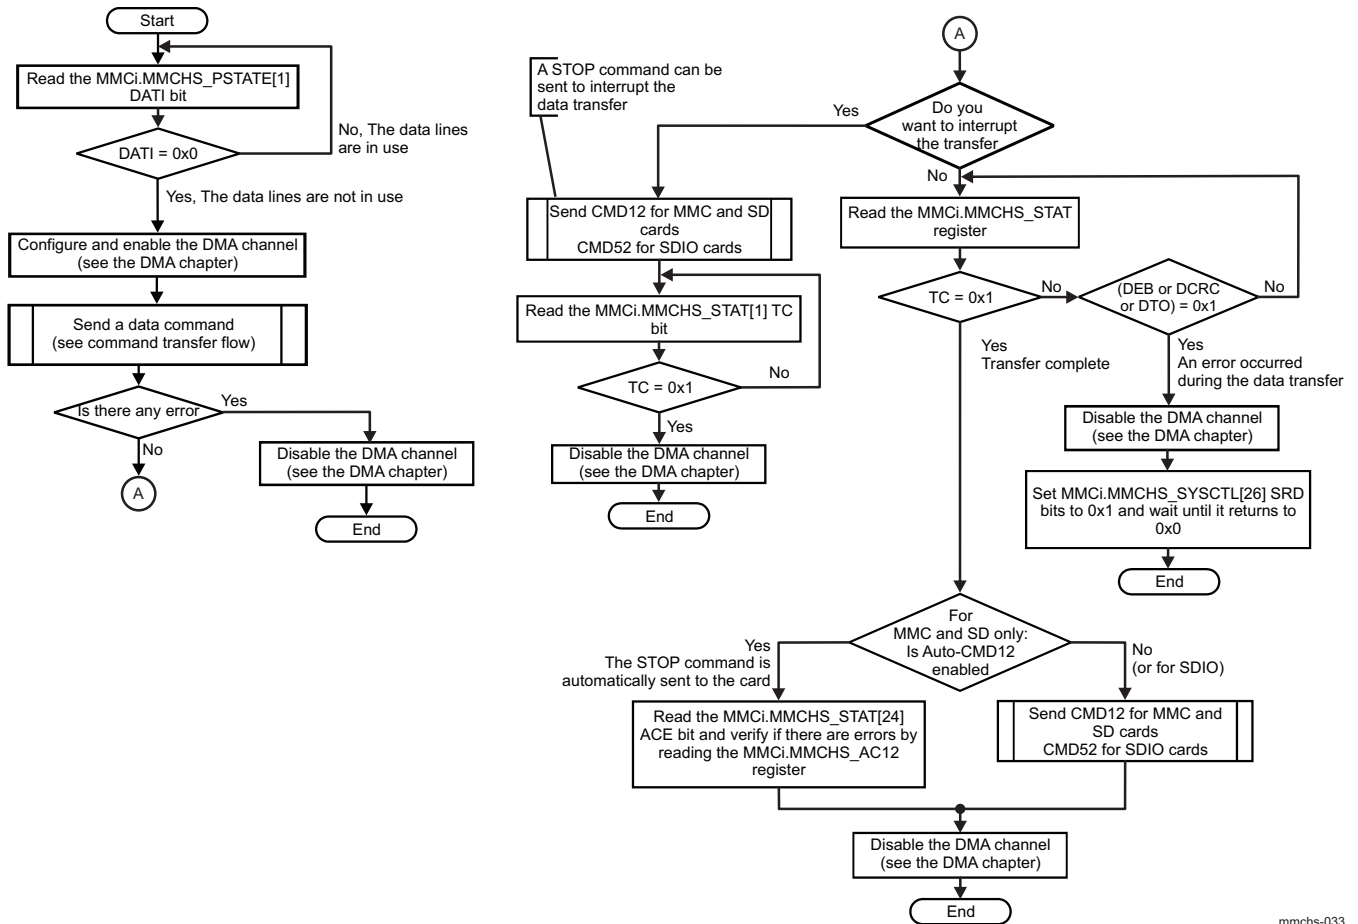

Figure 24-37. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode With Interrupt

mmchs-032

24.5.2.3 Read/Write Transfer Flow in DMA Mode With Polling

Figure 24-38 describes the read and write protocol in DMA mode. See Chapter 11, *SDMA*, for more information on the DMA settings.

Figure 24-38. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode With Polling

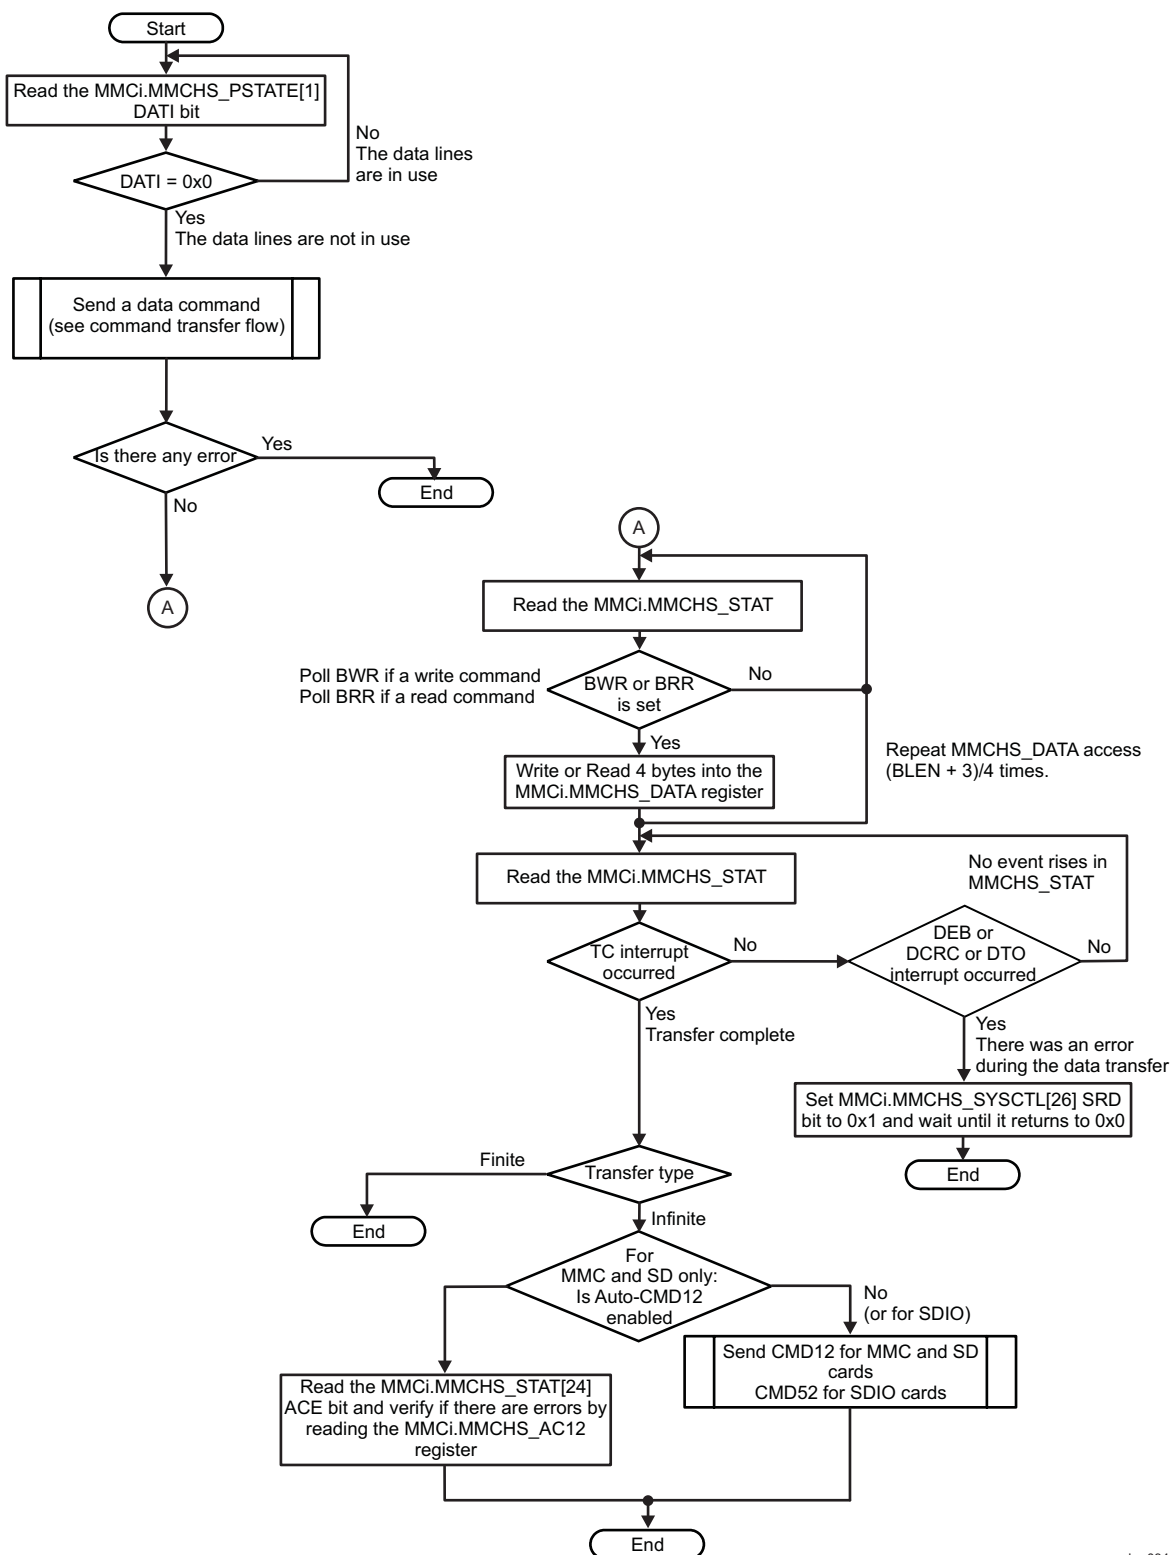

mmchs-033

24.5.2.4 Read/Write Transfer Flow Without DMA and With Polling

Figure 24-39 describes a read/write transfer without using the DMA and with polling.

Figure 24-39. MMC/SD/SDIO Controller Read/Write Transfer Flow Without DMA and With Polling

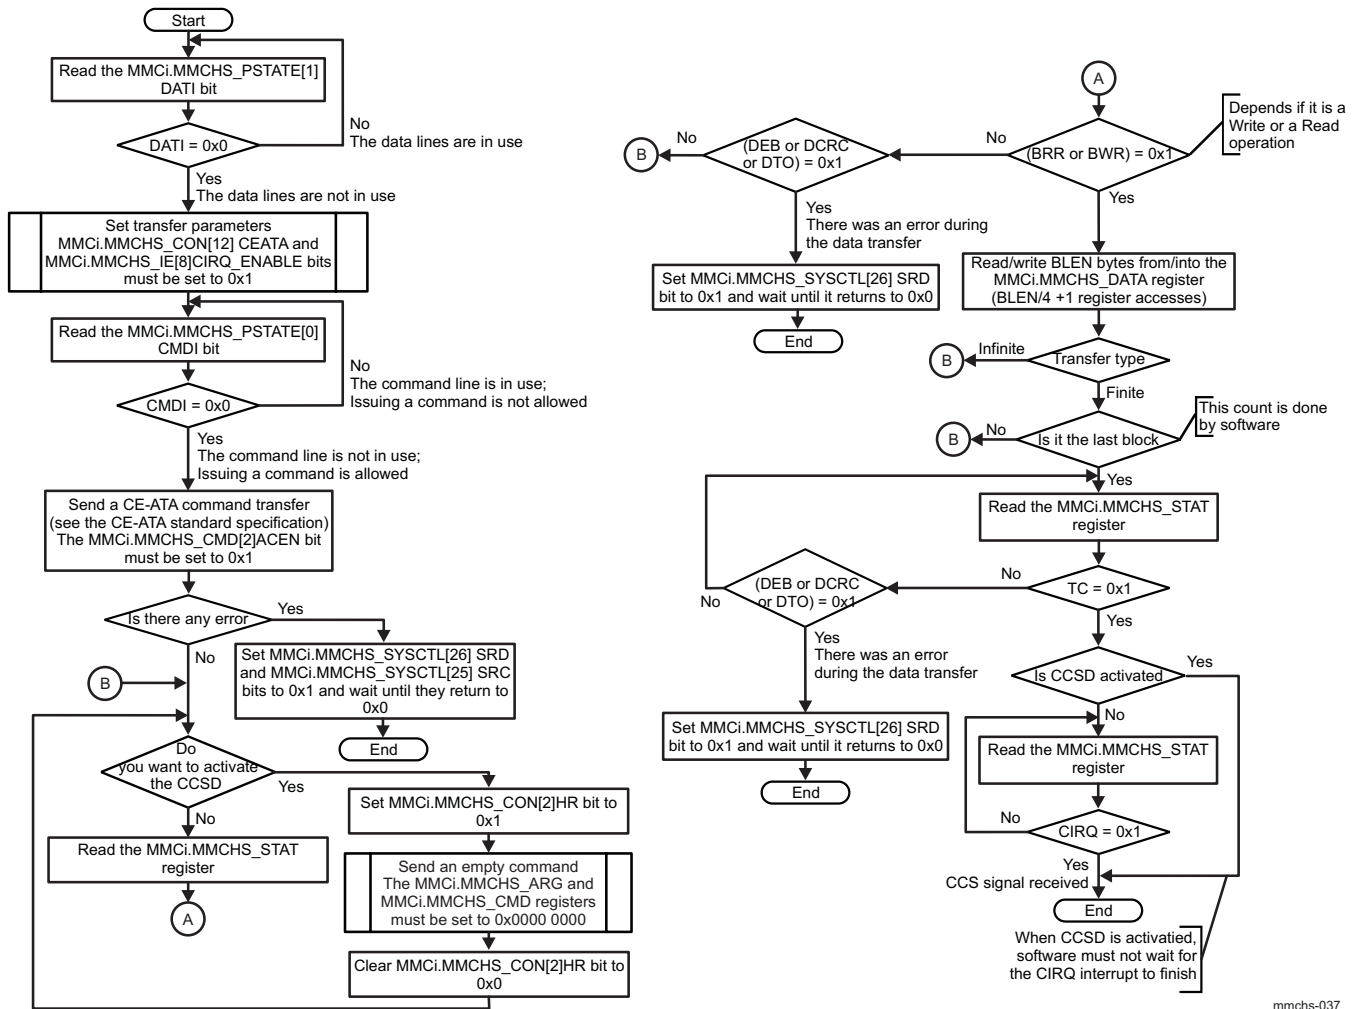

mmchs-034

24.5.2.5 Read/Write Transfer Flow in CE-ATA Mode

Figure 24-40 describes the read and write CE-ATA protocol when in Polling mode.

Figure 24-40. MMC/SD/SDIO Controller Read/Write in CE-ATA Mode

mmchs-037

CAUTION

CE-ATA protocol is only supported by MMC cards.

In CE-ATA mode, issuing command during the transfer (except a CCSD command) is not allowed

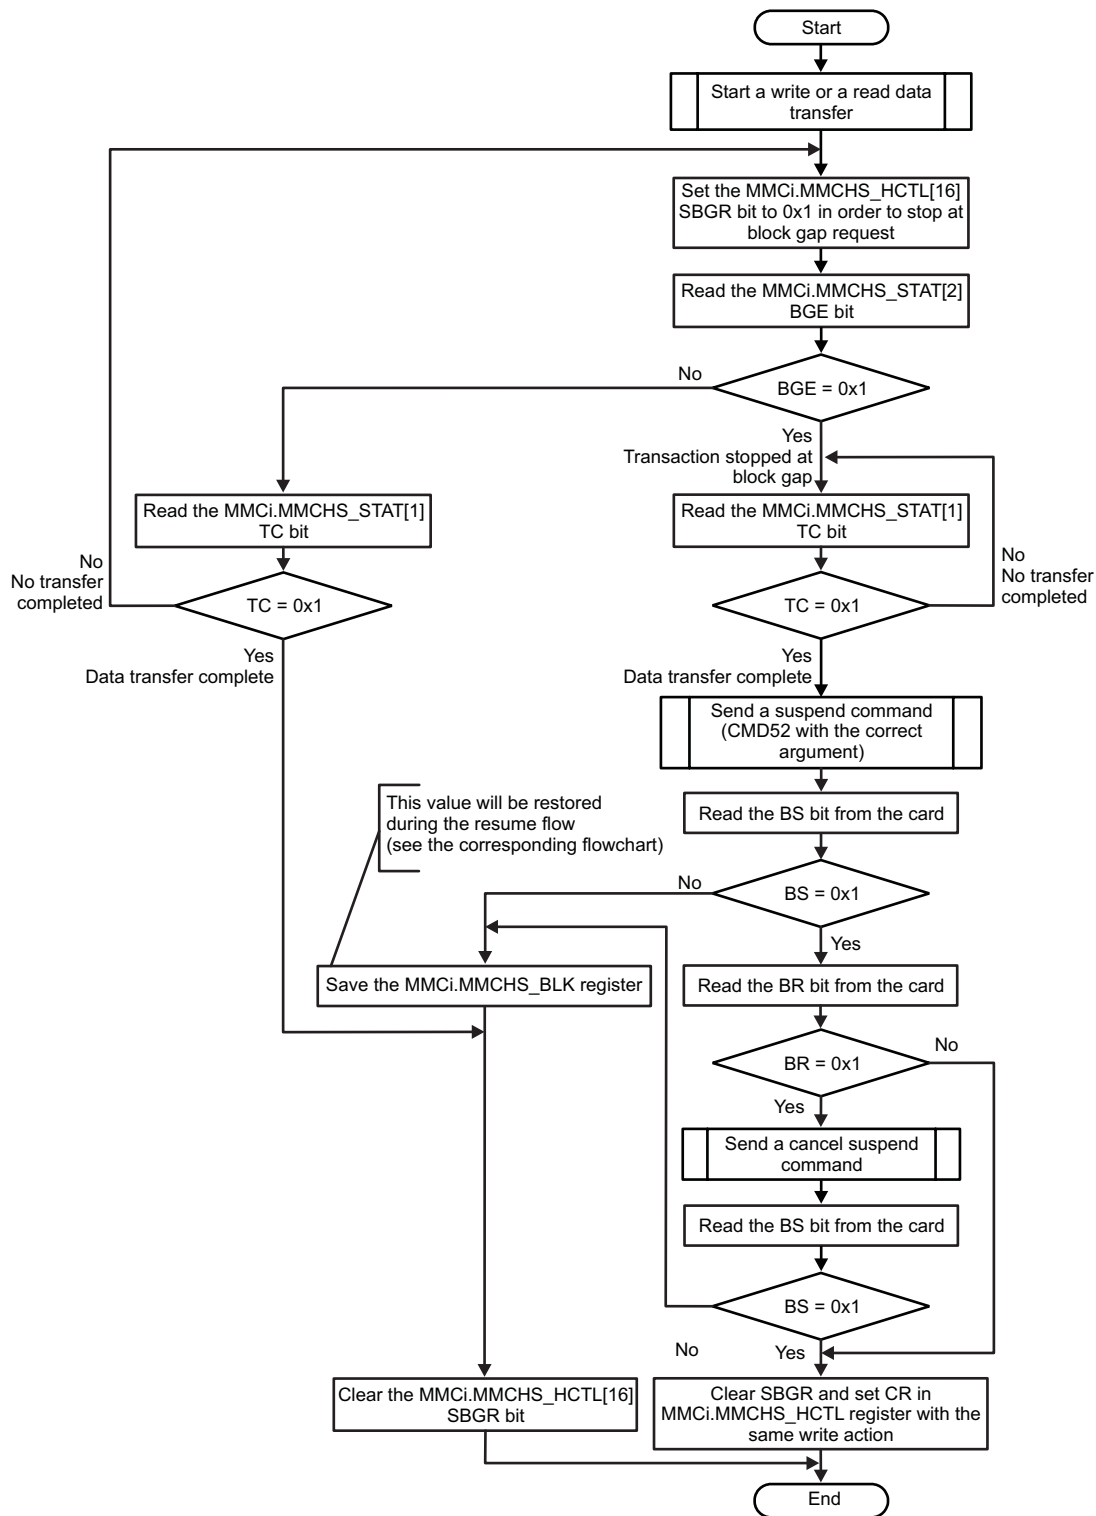

In CE-ATA mode, infinite transfers are not allowed, only finite transfers are permitted.

24.5.2.6 Suspend-Resume Flow

The suspend and resume feature is only supported by SDIO cards.

24.5.2.6.1 Suspend Flow

Figure 24-41 describes the suspend flow for SDIO cards.

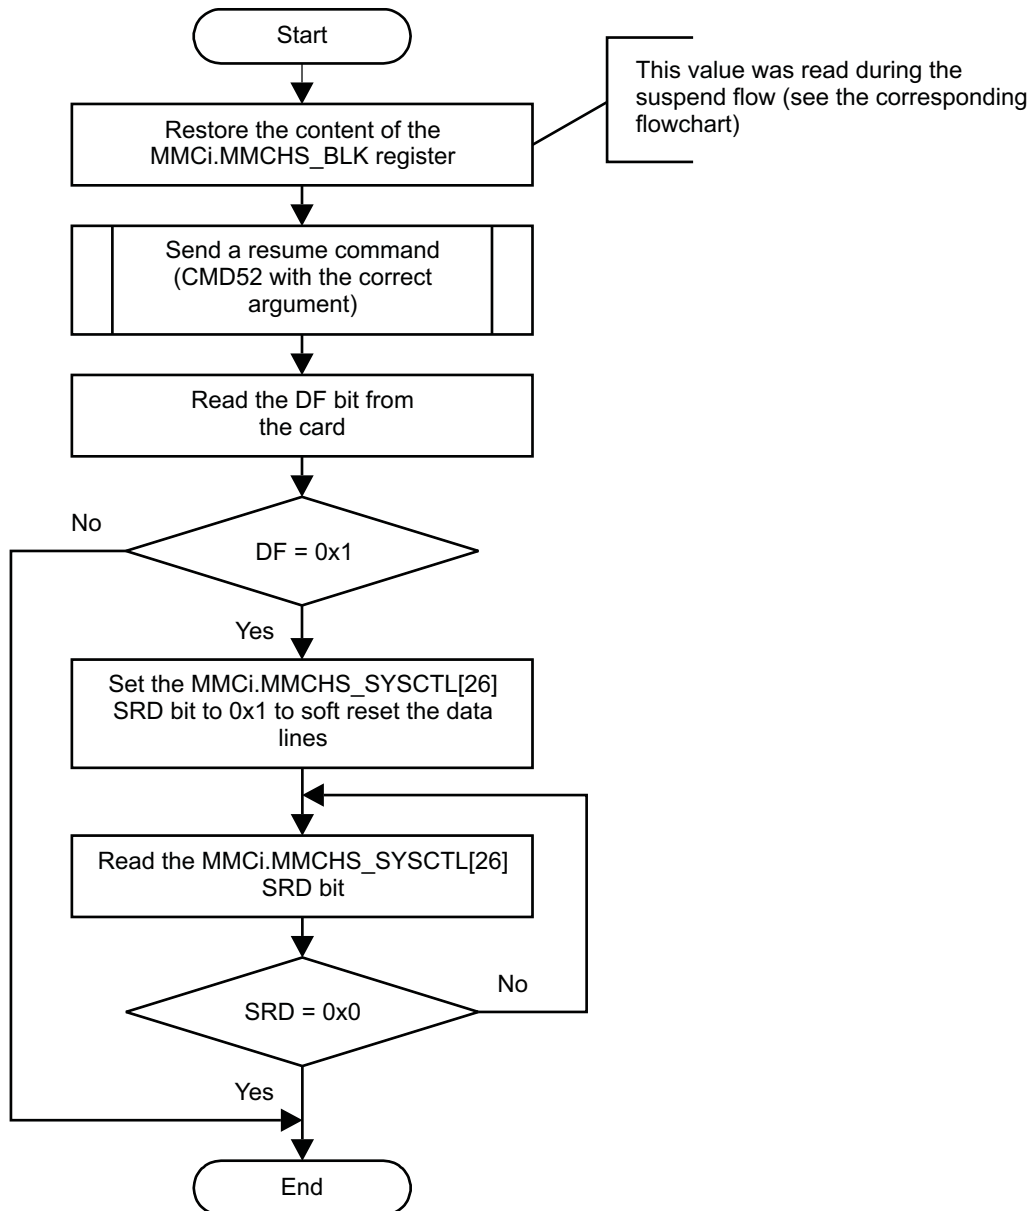

Figure 24-41. MMC/SD/SDIO Controller Suspend Flow

mmchs-038

24.5.2.6.2 Resume Flow

Figure 24-42 describes the resume flow for SDIO cards.

Figure 24-42. MMC/SD/SDIO Controller Resume Flow

mmchs-039

24.5.2.7 Basic Operations - Step Details

24.5.2.7.1 Command Transfer Flow

Figure 24-43 describes how to send a command to the card using polling instead of interrupts for event signaling.

Figure 24-43. MMC/SD/SDIO Controller Command Transfer Flow With Polling

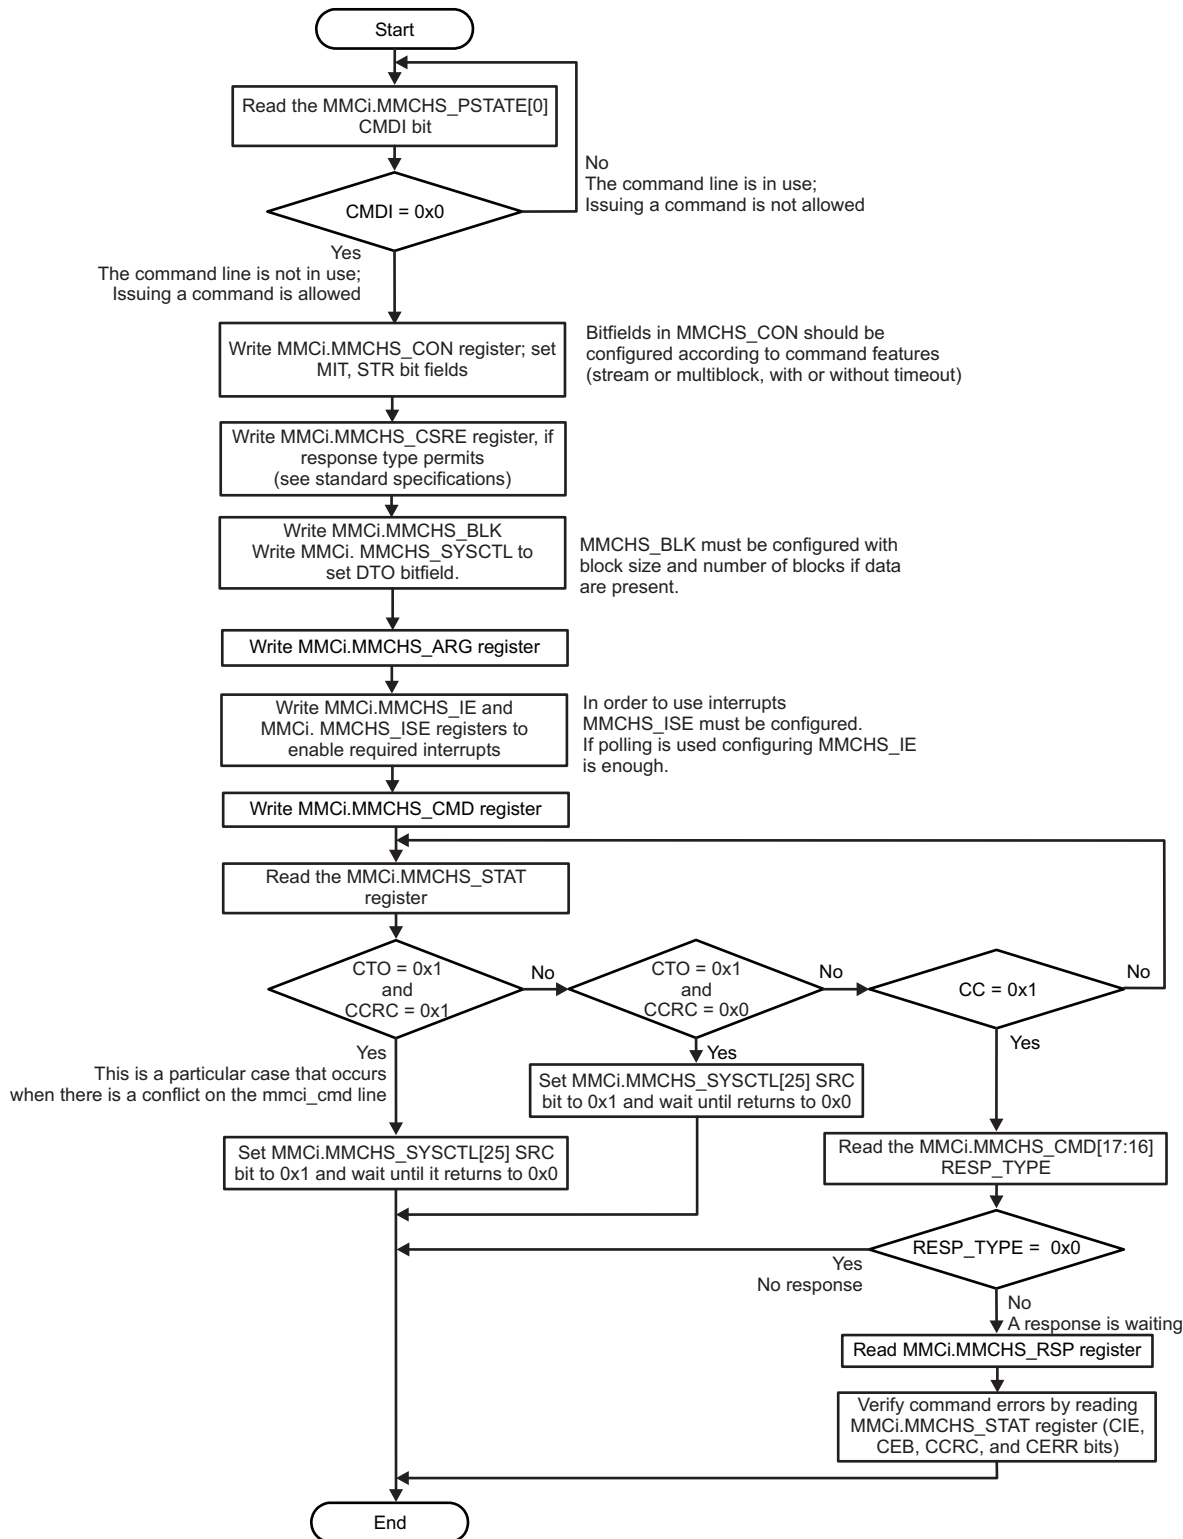

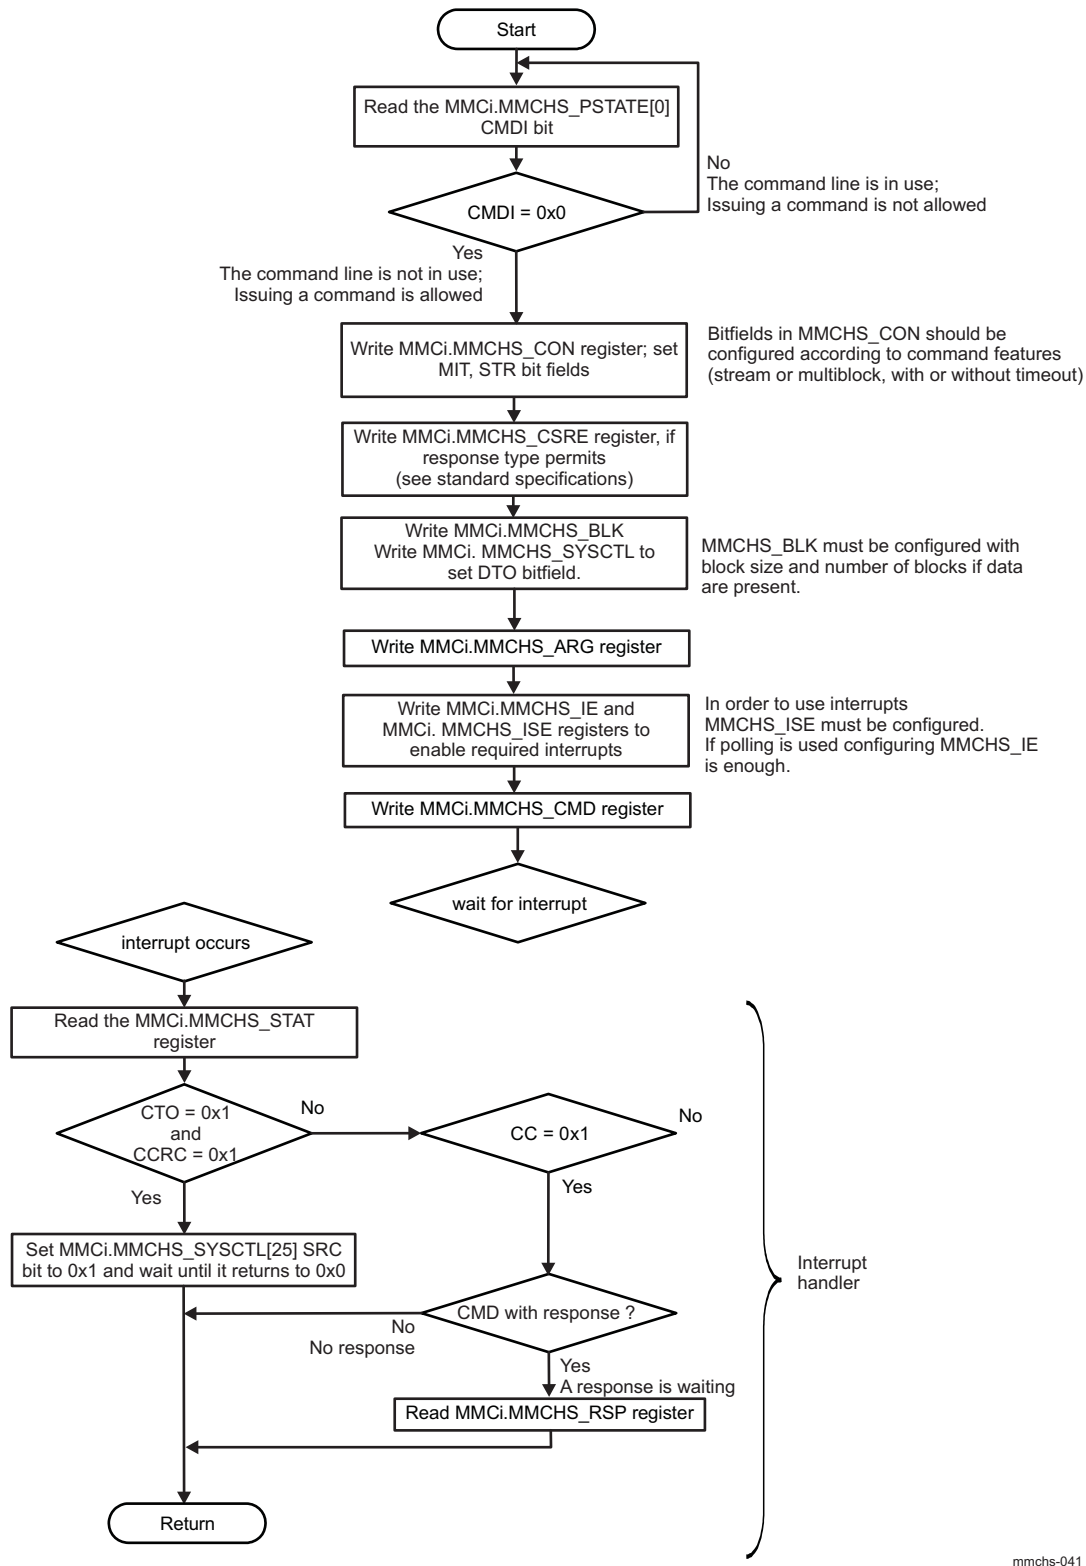

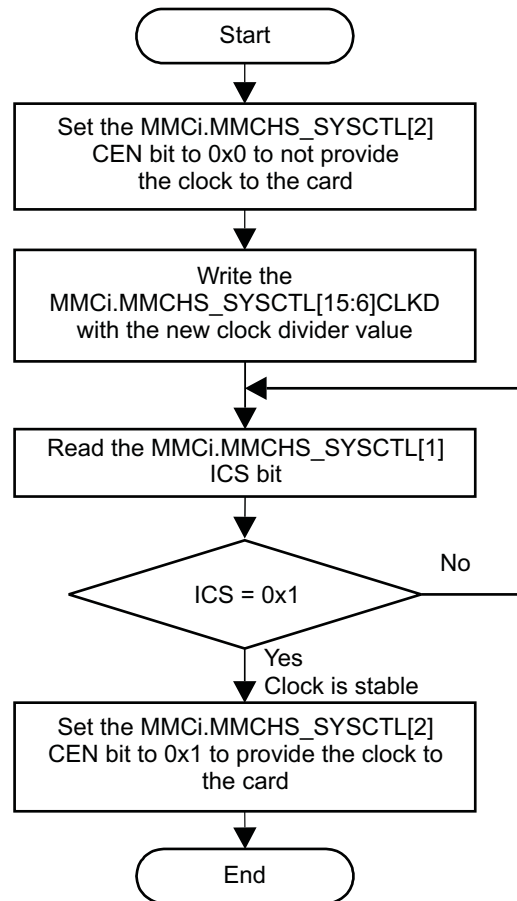

Figure 24-44 describes how to send a command to the card using interrupts for event signaling.

Figure 24-44. MMC/SD/SDIO Controller Command Transfer Flow With Interrupts

24.5.2.7.2 MMCHS Clock Frequency Change

Figure 24-45 describes the different steps that allow to change the MMC/SD/SDIO output clock frequency.

Figure 24-45. MMC/SD/SDIO Controller Clock Frequency Change Flow

mmchs-042

24.5.3 MMC/SD/SDIO1 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns those pads must have an internal bias voltage reference to operate. The PBIAS_LITE module supplies this bias voltage, depending on the CONTROL.CONTROL_PBIAS_LITE register settings.

See [Section 13.4.5, Extended-Drain I/O Pin and PBIAS Cell](#), for more information about the PBIAS_LITE cell.

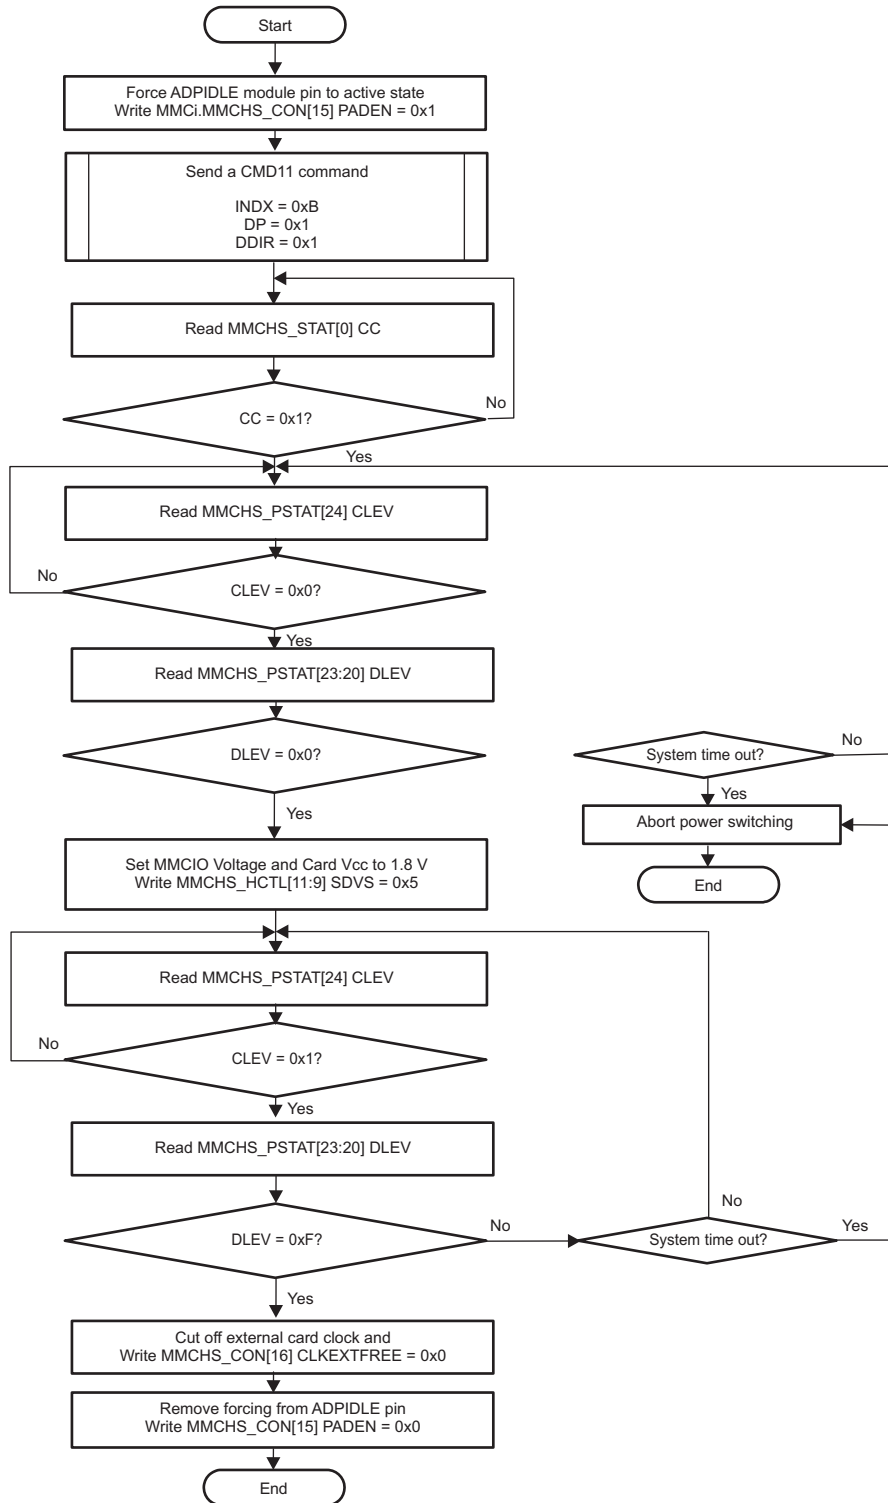

[Section 13.5.2, Extended-Drain I/Os and PBIAS Cell Basic Programming Guide](#), describes the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller.

CAUTION

The BIAS voltage must be set using the procedure described in [Section 13.5.2, Extended-Drain I/Os and PBIAS Cell Basic Programming Guide](#). Failure to follow this procedure can damage the MMCHS interface.

[Figure 24-46](#) describes how to configure the MMCHS controller to fit with power switching sequence.

Figure 24-46. MMC/SD/SDIO Power Switching Procedure

mmchs-055

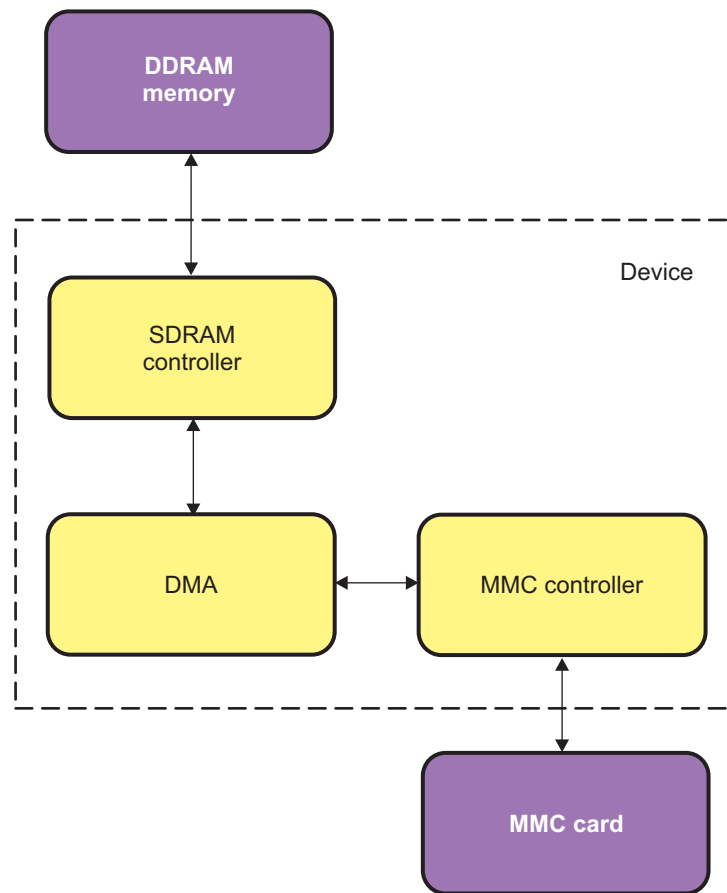

24.6 MMC/SD/SDIO Use Cases and Tips

24.6.1 MMCHS Controller Usage

24.6.1.1 Overview

The MMCHS controller is in charge of managing raw data storage in a MMC memory card. The MMCHS controller transfers data between DDRAM and MMC card. [Figure 24-47](#) gives an overview of MMCHS controller position in the use case.

Figure 24-47. Overview

mmchs_050

For the Camcorder use case, the MMCHS controller is configured to operate with the following features :

- High speed mode with a card clock frequency of 48 MHz.
- 4 data lines.
- 1.8 V and 3.0 V voltage capabilities.

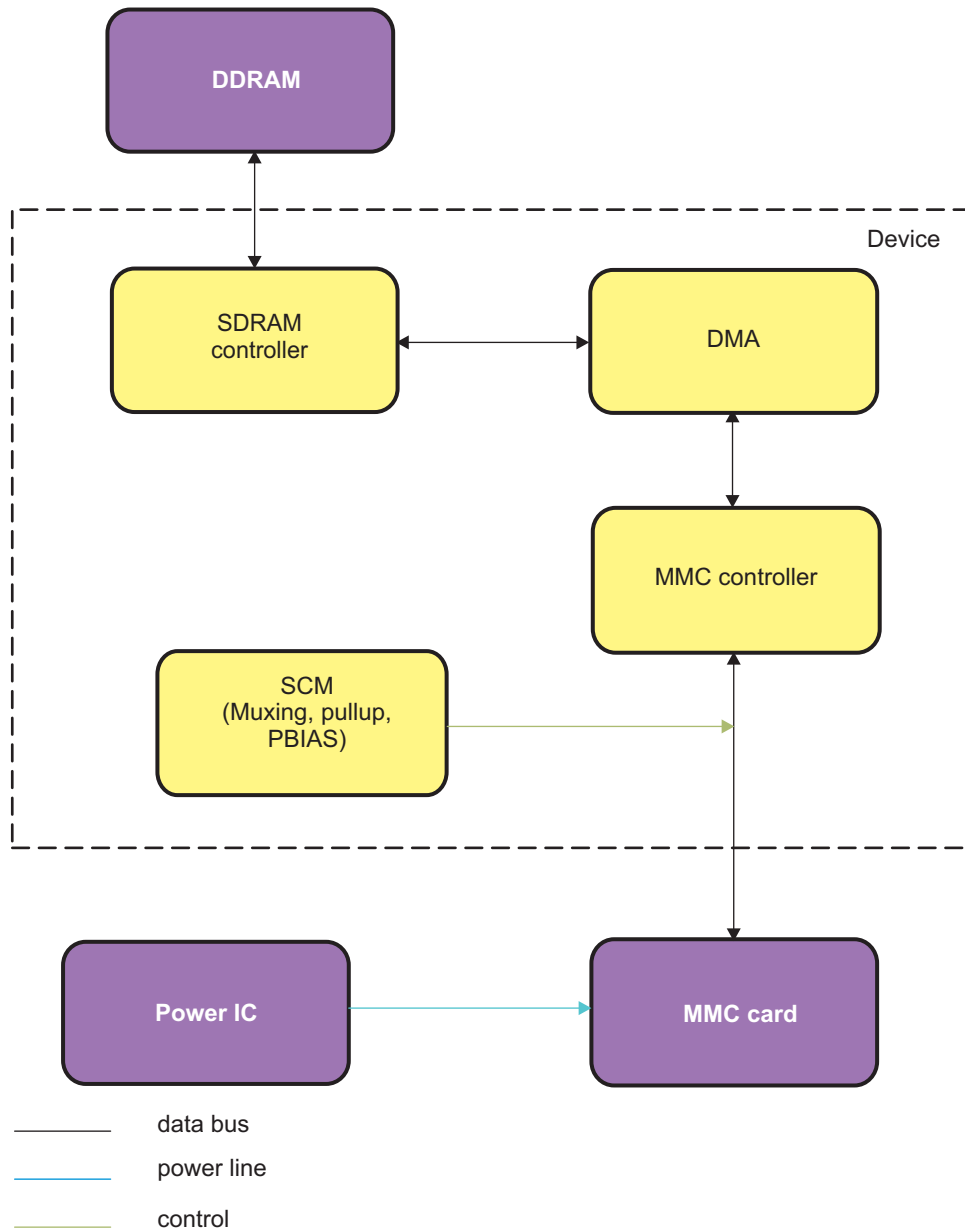

MMC card power supply is not provided by the MMCHS controller itself but rather by the companion device. See [Chapter 17](#) to learn how to set these voltage levels.

Only MMC1 controller is used in this configuration. Hence this document describes the output of the test carried out with MMC1 controller.

24.6.1.2 Environment

To operate in the correct manner, the MMCHS controller needs the System Control Module (SCM) to be configured with the right muxing mode and with the right pull up state. The MMC card needs to be powered with the right power level and this is done with the companion device. Figure 24-48 gives the environment picture of the MMCHS controller.

Figure 24-48. Environment

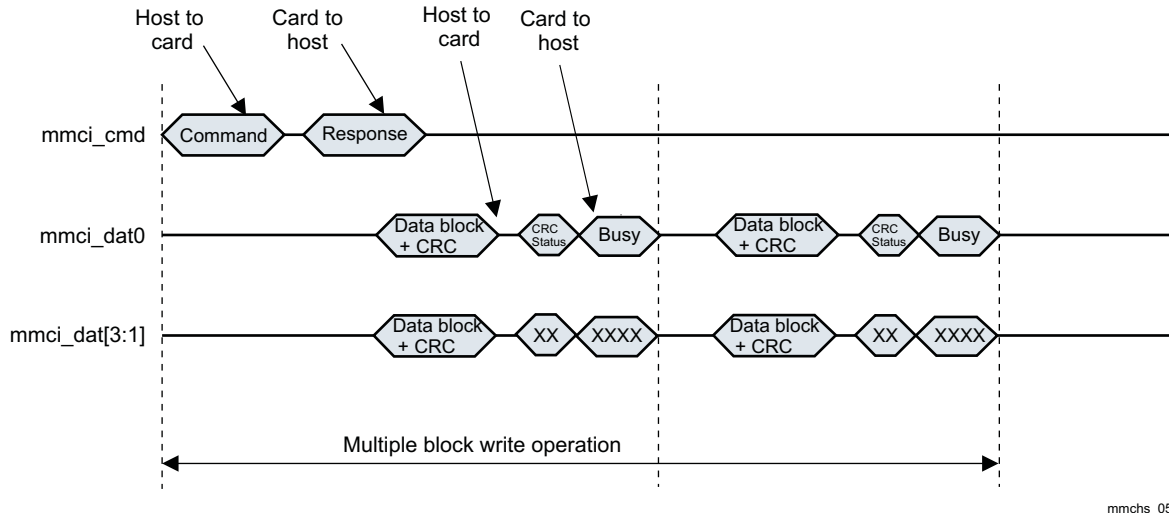

mmchs_GN3-001

24.6.1.2.1 Command and Data Transfer Formats

When communicating with a MMC card, The MMCHS controller is always the master. The communication between the MMCHS controller and the MMC card always starts by sending a command. Both command and data transfers are started with a command.

The data transfer type used by the MMCHS controller is a finite multiple block transfer. Figure 24-49 illustrates a command transfer without data. Figure 24-50 and Figure 24-51 illustrate a multiple block transfer between the MMCHS controller and the MMC card.

Figure 24-49. Command Transfer**Figure 24-50. Data Read Transfer****Figure 24-51. Data Write Transfer**

24.6.1.3 Programming Flow

24.6.1.3.1 Initial Configuration

The initialization of the MMCHS controller is done through these steps :

1. MMCHS controller interface and functional clocks enabling.
2. MMCHS controller software reset.
3. MMCHS controller voltage capabilities initialization.
4. MMCHS controller default initialization.
5. MMCHS controller INIT procedure start.

6. MMCHS controller pre-card identification configuration.

For more information about different steps the MMCHS controller goes through during initial configuration see [Section 24.5](#), *MMC/SD/SDIO Basic Programming Model*.

24.6.1.3.1.1 MMCHS Controller Interface and Functional Clocks Enabling

In order to enable the interface and functional clocks of the MMCHS1 controller, the following steps must be done:

1. Enable the interface clock for the MMCHS1 controller (set the PRCM.CM_ICLKEN1_CORE[24] EN_MMCHS1).
2. Enable the functional clock for the MMCHS1 module (set the PRCM.CM_FCLKEN1_CORE[24] EN_MMCHS1).

[Table 24-8](#) shows all PRCM registers to be configured to enable interface and functional clocks for MMCHS1 controller.

Table 24-8. Register Print for the MMCHS1 Controller Clock Initialization

Register Name	Register Address	Value	Value Description
PRCM.CM_ICLKEN1_CORE	0x4800 4A10	0x01000000	MMCHS1 interface clock enabled
PRCM.CM_FCLKEN1_CORE	0x4800 4A00	0x01000000	MMCHS1 functional clock enabled

24.6.1.3.1.2 MMCHS Controller Software Reset

To software-reset the MMCHS1 controller, the following steps must be performed:

1. Write 0x2 in MMCHS1.MMCHS_SYSCONFIG register.
2. Wait until MMCHS1.MMCHS_SYSSTATUS[0] RESETDONE turns 1.

[Table 24-9](#) describes the software-reset registers.

Table 24-9. Software-Reset Register Description

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCONFIG	0x4809 C010	0x00000002	Activate software reset.
MMCHS1.MMCHS_SYSSTATUS	0x4809 C014	0x00000001	Reset is over.

24.6.1.3.1.3 MMCHS Controller Voltage Capabilities Initialization

MMCHS1 controller's voltage capabilities should be set in MMCHS1.MMCHS_CAPA. See [Table 24-10](#).

Table 24-10. MMCHS Controller Voltage Capabilities Initialization

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CAPA	0x4809 C140	current_value 0x06000000	Activate VS18 and VS30 in the MMCHS_CAPA register.

24.6.1.3.1.4 MMCHS Controller Default Initialization

Before sending any command, the MMCHS controller is configured with default values:

1. Default voltage support is set to 1.8 V in MMCHS1.MMCHS_HCTL[11:9] SDVS.
2. MMC bus is set to open drain in MMCHS1.MMCHS_CON[0] OD.
3. MMC data bus width is set to 1 in MMCHS1.MMCHS_HCTL[1] DTW.
4. MMC Card's power is off.
5. MMC card's clock is on in MMCHS1.MMCHS_SYSCTL[0] ICE and MMCHS1.MMCHS_SYSCTL[2] CEN.
6. MMCHS controller bus power up in MMCHS1.MMCHS_HCTL[8] SDBP.

7. MMC card's clock frequency is set to 150 kHz in MMCHS1.MMCHS_SYSCTL[15:6] CLKD.

Table 24-11 shows the values that must be written in the right register pool.

Table 24-11. MMC Controller Default Initialization Values

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	data bus width = 1, voltage = 1.8 V, MMC bus power is on (not card's power)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x0000a007	card's clock enable and card's clock frequency divider
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open-drain.

A small notice about MMCHS1.MMCHS_HCTL. Even if the value written in it is 0x00000b00, the value read from it is equal to 0x00000a00. This is due to the fact that the MMCHS controller is not in a card state mode which sets automatically the MMCHS_HCTL[8] SDBP bit to 0.

24.6.1.3.1.5 MMCHS Controller INIT Procedure Start

Prior to issuing any command, the MMCHS controller has to execute a special INIT procedure. The MMCHS controller has to generate a clock during 1ms. During the INIT procedure, the MMCHS controller generates 80 clock periods. In order to keep the 1 ms gap, the MMCHS controller should be configured to generate a clock whose frequency is smaller or equal to 80 kHz.

The INIT procedure is executed by setting MMCHS1.MMCHS_CON[1] INIT bit field to 1 and by sending a dummy command, writing 0x00000000 in the MMCHS1.MMCHS_CMD register.

To assure the synchronous clock on the clock output of the MMC1 controller, set the CONTROL.CONTROL_PADCONF_MMC1_CLK[8] bit. In this way, the clock output is also configured as input and the result is looped back through the output and input buffers of the pad.

Table 24-12 shows the values that should be written in the right register pool.

Table 24-12. MMCHS Controller INIT Procedure Start

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	current_value 0x00000002	Sets MMCHS1.MMCHS_CON[1] INIT to 1
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	Sends dummy command.
CONTROL.CONTROL_PADCONF_MMC1_CLK	0x4800 2144	0x100	Set the INPUTENABLE bit to assure the synchronous clock.

24.6.1.3.1.6 MMCHS Controller Precard Identification Configuration

Before card identification starts, the MMCHS controller's configuration should change. The MMC card's clock should now be 400 kHz, according to the MMC system spec requirements. Table 24-13 shows the values that should be written in the right register pool.

Table 24-13. MMCHS Controller Precard Identification Configuration

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000b00	Data bus width = 1, voltage = 1.8 V, MMC bus power is on (not power of card)
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	Card's clock enable and card's clock frequency divider
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	Set MMC bus mode to open drain.

24.6.1.3.2 MMC Card Identification

MMC card identification is performed by issuing many MMC commands. Each command imposes certain configuration values in a pool of registers. The status of command transfer is read in MMCHS1.MMCHS_STAT register and command response if any is read from MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76.

This TRM output describes a use case where interrupts are used to signal MMCHS controller status changes.

For more details about the card identification sequence, see [Section 24.5, MMC/SD/SDIO Basic Programming Model](#).

24.6.1.3.2.1 Sending CMD0

This command resets the MMC card (see [Table 24-14](#)).

Table 24-14. Sending CMD0

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00040001	Enables CC and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00040001	Enables CC and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x00000000	Sends CMD0 whose opcode is 0.

24.6.1.3.2.2 Sending CMD5

This command asks a SDIO card to send its operating conditions (see [Table 24-15](#)). This command will fail if there is no SDIO card. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 24-15. Sending CMD5

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x05020000	Sends CMD5 whose opcode is 5 and response type is 48 bits.

24.6.1.3.2.2.1 Sending CMD8

This command asks a SD card version 2.X to send its operating conditions (see [Table 24-16](#)). This command will fail if there is no SD card version 2.X. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 24-16. Sending CMD8

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x81a0000	Sends CMD8 whose opcode is 8, response type is 48 bits with CICE and CCCE enabled.

24.6.1.3.2.3 Sending CMD55

This is a special command used to prevent the card that the following command is going to be an application one (see [Table 24-17](#)). This is used to prepare the issuing of ACMD41 (opcode = 41) that usually asks a SD card version 1.X to send its operating conditions. If no SD card version 1.X is connected to the MMCHS controller this command will fail. In case of success the response will be received in the MMCHS1.MMCHS_RSP10 register.

Table 24-17. Sending CMD55

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x371a0000	Sends CMD55 whose opcode is 55, response type is 48 bits with CICE and CCCE enabled.

24.6.1.3.2.4 Sending CMD1

Once the card response is available in register MMCHS1.MMCHS_RSP10, the software is responsible to compare Card OCR and Host OCR, and then send a second CMD1 command with the cross-checked OCR.

This way, the card is notified of the Operating Voltage to work with.

Table 24-18. Sending CMD1

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00050001	Enables CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00050001	Enables CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x01020000	Sends CMD1 whose opcode is 1 and response type is 48 bits.

Once the card response is available in register MMCHS1.MMCHS_RSP10, the software should compare card OCR and host OCR, and then send a second CMD1 command with the cross-checked OCR. This tells the card what operating voltage to use.

24.6.1.3.2.5 Sending CMD2

This command asks the MMC card to send its CID register's content (see [Table 24-19](#)). The response is 128 bits wide and is received in the MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76 registers.

Table 24-19. Sending CMD2

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x02090000	Sends CMD2 whose opcode is 2, response type is 136 bits with CCCE enabled.

24.6.1.3.2.6 Sending CMD3

This command sets the MMC card address (see [Table 24-20](#)). Useful when the MMCHS controller switches to addressed mode.

Table 24-20. Sending CMD3

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000001	MMC bus is still in open drain state for broadcast.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x031a0000	Sends CMD3 whose opcode is 3, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

24.6.1.3.3 MMC Bus Setting Change After Card Identification

After the CMD3 command transfer is completed successfully, an auto-negotiation on voltage value an start. This is the frontier when the MMCHS controller should switch from identification mode to transfer mode. This impacts the controller in a way that it should change its bus state from open drain to push-pull. [Table 24-21](#) gives several registers and their values.

Table 24-21. MMC Bus Setting Change Table

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	Bus is now in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000B00	Bus power is on, 1.8 V is selected.
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00003C07	The internal clock of theMMCHS controller is stable and enabled, and the MMC card clock is on. The divider value is 240, which means the MMCHS controller is still supplying a 400-kHz clock.

24.6.1.3.4 Reading the CSD Register of an MMC Card

After settling on a voltage value, additional information must be read from the MMC card. This data is stored in MMC card CSD register. The card sends CSD register content after receiving CMD9 command. The CSD register holds important information on the card, MMC system specification version support, maximum clock speed support, memory capacity, minimum block length, and read and write transfer latency timings.

24.6.1.3.4.1 Sending CMD9

This command asks the card to send its CSD register 's content (see [Table 24-22](#)). The 136-bit (128 bits are valid payload) response is received in the MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54, and MMCHS1.MMCHS_RSP76 registers. CMD9 is an addressed command which means that the card's address must be written in the MMCHS1.MMCHS_ARG register before the command is issued.

Table 24-22. Sending CMD9

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x00070001	Enables CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x00070001	Enables CCRC, CC, CTO and CEB interrupts to rise.

Table 24-22. Sending CMD9 (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CMD	0x4809C10C	0x09090000	Sends CMD9 whose opcode is 9, response type is 136 bits with CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After receiving and parsing CMD9 response, MMC card clock speed must change to take advantage to card's maximum speed. This has an impact on MMC bus as we should perform a clock frequency change. At this stage the maximum clock frequency will be 20 MHz (see MMC system specification from www.mmca.org).

Clock frequency change procedure is performed in several steps. Please refer to [Section 24.5.2.7.2, MMCHS Clock Frequency Change](#).

[Table 24-23](#) shows the value written in MMCHS1.MMCHS_SYSCTL register.

Table 24-23. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000147	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 5 which means that MMCHS controller is supplying a 19.2 MHz clock < 20 MHz.

Another important parameter read from CSD register is MMC system specification version. If this parameter points to a value greater than or equal to 4, the MMC card is capable of a speed up to 52 MHz and a bus width up to 8 (1, 4 or 8 are the possible options). To enable these two extra features, MMCHS controller must issue a CMD6 command with specific argument.

A CMD6 command is issued in the data transfer mode after MMC card is selected. MMC card selection consists of sending CMD7 command with MMC card's address in command argument.

[Table 24-24](#) shows the set of register impacted by CMD7 issue action.

Table 24-24. Sending CMD7

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x071a0000	Sends CMD7 whose opcode is 7, response type is 48 bits with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00010000	MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid.

After a CMD7 transfer is complete, the MMC card is ready to receive a CMD6 command. CMD6 command is used to write a byte in MMC card extended CSD register (ext_csd). It is an IO access function. There are two write actions, the first one enables a specific data bus width in the card. For our use case we used data bus width 4. The second one enables high speed feature in the card.

24.6.1.3.4.1.1 Setting Data Bus Width to 4

[Table 24-25](#) shows the set of registers impacted by issuing CMD6.

Table 24-25. Setting Data Bus Width With CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b70100	$(3 \ll 24) (\text{byte_address} \ll 16) (\text{byte_value} \ll 8)$. byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should change its data bus width to 4. This is done by changing MMCHS1.MMCHS_HCTL configuration value.

Table 24-26. MMCHS_HCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.

24.6.1.3.4.1.2 Enable High-Speed Feature

Table 24-27 shows the set of registers impacted by issuing CMD6 issuing.

Table 24-27. Enabling High-Speed With CMD6

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x061b0000	Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x03b90100	$(3 \ll 24) (\text{byte_address} \ll 16) (\text{byte_value} \ll 8)$. byte_address is the byte address in ext_csd register.

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should now change its output clock to bring it to 48 MHz. 52 MHz, max frequency value supported by MMC card version 4 and above, is not supported because 96 MHz, MMCHS controller functional clock, is not a multiple of 52 MHz. We fall off to 48 MHz.

Table 24-28. MMCHS_SYSCTL Value

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_SYSCTL	0x4809C12C	0x00000087	MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 2 which means that MMCHS controller is supplying a 48 MHz clock.

24.6.1.3.5 MMC Write Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this chapter, it is described in [Chapter 11, SDMA](#).

Before any data transfer begins, the card must selected by issuing CMD7 command ([Table 24-24](#)).

A write transfer is a finite multiple block write transfer. To perform a write transfer, the following steps must be performed.

24.6.1.3.5.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 24-29. Setting Block Length

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x101a0000	Sends CMD16 whose opcode is 16, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000200	Block length is 512 = 0x200

24.6.1.3.5.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 24-30. Setting Number of Blocks

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x100f0001	Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x171a0000	Sends CMD23 whose opcode is 23, response type is 48 bits, with CICE and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000008	Number of 512-byte blocks in 4 KB buffer is 8.

24.6.1.3.5.3 Send CMD25

Issuing CMD25 starts the finite, multiple block write transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration see [Chapter 11, SDMA](#).

Table 24-31. CMD25 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0013	Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x193a0023	Sends CMD25 whose opcode is 25, response type is 48 bits, with CICE, DP, MSBS, BCE, DE and CCCE enabled.

Table 24-31. CMD25 Issuing (continued)

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) (block_length)

24.6.1.3.6 MMC Read Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this document, it is described in [Chapter 11, SDMA](#).

Before any data transfer begins, the card must be selected by issuing CMD7 command ([Table 24-24](#)).

A read transfer is a finite multiple block write transfer. To perform a read transfer, the following steps must be performed.

24.6.1.3.6.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. See [Table 24-29](#).

24.6.1.3.6.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. See [Table 24-30](#).

24.6.1.3.6.3 Send CMD18

Issuing CMD18 starts the finite, multiple block read transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration see [Chapter 11, SDMA](#).

Table 24-32. CMD18 Issuing

Register Name	Register Address	Value	Value Description
MMCHS1.MMCHS_CON	0x4809C02C	0x00000000	MMC bus is in push-pull mode.
MMCHS1.MMCHS_HCTL	0x4809C128	0x00000002	MMCHS controller's data bus width is set to 4.
MMCHS1.MMCHS_IE	0x4809C134	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB events to occur.
MMCHS1.MMCHS_ISE	0x4809C138	0x107f0023	Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB interrupts to rise.
MMCHS1.MMCHS_CMD	0x4809C10C	0x123a0033	Sends CMD18 whose opcode is 18, response type is 48 bits, with CICE, DP, MSBS, BCE, DE, DDIR and CCCE enabled.
MMCHS1.MMCHS_ARG	0x4809C108	0x00000000	Not used
MMCHS1.MMCHS_BLK	0x4809C104	0x00080200	(number_blocks << 16) (block_length)

24.6.1.3.7 Dealing With High-Capacity Cards

Unlike standard-capacity cards, memory addressing mode for high-capacity cards (SDHC and HC MMC) is in 512-byte block format instead of byte format. This means that byte and partial accesses are not allowed with high-capacity cards.

The 32-bit wide argument configured in the [MMCHS_ARG](#) register and sent in data transfer commands CMD17, CMD18, CMD24, and CMD25, carries the block index where the read/write should start and not the 32-bit byte address.

For high-capacity cards, the block size is fixed at 512 bytes. Any data transfer, when the data bus is involved, must be a multiple of 512 bytes.

The number of blocks for a high-capacity card, which determines the capacity of the card block_count x 512 bytes, is accessible through field C_SIZE in the card s CSD register version 2.0 for SD cards, or through the SEC_COUNT field in the card s EXT_CSD register for MMC cards compliant with MMC specification version 4.x.

To write/read a packet whose size is less than 512 bytes to/from a high-capacity card, write/read the whole 512-byte block that contains the range of bytes to modify/read.

Physical Address	0x4809 C010	Instance	MMCHS1
	0x480A D010		MMCHS3
	0x480B 4010		MMCHS2
Description	System Configuration Register This register allows controlling various parameters of the Interconnect interface.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																CLOCKACTIVITY		Reserved			SIDLEMODE	ENAWAKEUP	SOFTRESET	AUTOIDLE							

Bits	Field Name	Description	Type	Reset
31:10	Reserved	These bits are initialized to zero, and writes to them are ignored. Reads return 0	R	0x00000
9:8	CLOCKACTIVITY	Clocks activity during wake up mode period. Bit8: Interface clock Bit9: Functional clock 0x0: Interface and Functional clock may be switched off. 0x1: Interface clock is maintained. Functional clock may be switched-off. 0x2: Functional clock is maintained. Interface clock may be switched-off. 0x3: Interface and Functional clocks are maintained.	RW	0x0
7:5	Reserved	These bits are initialized to zero, and writes to them are ignored. Reads return 0	R	0
4:3	SIDLEMODE	Power management 0x0: If an idle request is detected, the MMC/SD/SDIO host controller acknowledges it unconditionally and goes in Inactive mode. Interrupt and DMA requests are unconditionally deasserted. 0x1: If an idle request is detected, the request is ignored and the module keeps on behaving normally. 0x2: If an idle request is detected, the module will switch to wake up mode based on its internal activity, and the wake up capability can be used if the wake up capability is enabled (bit MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 1). 0x3: Reserved - do not use	RW	0x2
2	ENAWAKEUP	Wake-up feature control 0x0: Wake-up capability is disabled 0x1: Wake-up capability is enabled	RW	1
1	SOFTRESET	Software reset. The bit is automatically reset by the hardware. During reset, it always returns 0. Read 0x0: Normal mode Write 0x0: No effect. Read 0x1: The module is reset. Write 0x1: Trigger a module reset.	RW	0
0	AUTOIDLE	Internal Clock gating strategy 0x0: Clocks are free-running	RW	1

Bits	Field Name	Description	Type	Reset
		0x1: Automatic clock gating strategy is applied, based on the interconnect and MMC interface activity

Physical Address	0x4809 C024	Instance	MMCHS1
	0x480A D024		MMCHS3
	0x480B 4024		MMCHS2
Description	Card status response error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCi.MMCHS_CSRE[I] is set to 1, if the corresponding bit at the same position in the response MMCi.MMCHS_RSP10[I] is set to 1, the host controller indicates a card error (MMCi.MMCHS_STAT[28] CERR bit) interrupt status to avoid the host driver reading the response register (MMCi.MMCHS_RSP10). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCi.MMCHS_RSP76) for possible card errors.

Table 24-41. MMCHS_SYSTEST

Address Offset	0x028		
Physical Address	0x4809 C028	Instance	MMCHS1
	0x480A D028		MMCHS3
	0x480B 4028		MMCHS2
Description	System Test register This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification. Note: In SYSTEST mode, a write into MMCi.MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCi.MMCHS_BLK[10:0] BLEN bits) and the Blocks count for current transfer (MMCi.MMCHS_BLK[31:16] NBLK bits) are needed to generate a Buffer write ready interrupt (MMCi.MMCHS_STAT[4] BWR bit) or a Buffer read ready interrupt (MMCi.MMCHS_STAT[5] BRR bit) and DMA requests if enabled.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Address Offset	0x02C		
Physical Address	0x4809 C02C	Instance	MMCHS1
	0x480A D02C		MMCHS3
	0x480B 402C		MMCHS2
Description	Configuration register This register is used: - to select the functional mode for any card. - to send an initialization sequence to any card. - to enable the detection on the mmci_dat[1] signal of a card interrupt for SDIO cards only. And also to configure: - specific data and command transfers for MMC cards only. - the parameters related to the card detect and write protect input signals.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																CLKEXTFREE	PADEN	OBIE	OBIP	CEATA	CTPL	DVAL	WPP	CDP	MIT	DW8	MODE	STR	HR	INIT	OD

Bits	Field Name	Description	Type	Reset
31:17	Reserved	Reserved bit field. Do not write any value	R	0x00000
16	CLKEXTFREE	<p>External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmci_dat[1]). The Clock will be maintain only if MMCI.MMCHS_SYSCTL[2] CEN bit is set.</p> <p>0x0: External card clock is cut off outside active transaction period.</p> <p>0x1: External card clock is maintain even out of active transaction period only if MMCI.MMCHS_SYSCTL[2] CEN bit is set.</p>	RW	0
15	PADEN	<p>Control Power for MMC Lines. This register is only useful when MMC PADS contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADS. Excepted for mmci_dat[1], the signal is also combine outside the module with the dedicated power control MMCI.MMCHS_CON[11] CTPL bit.</p> <p>0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms.</p> <p>0x1: ADPIDLE module pin is forced to active state.</p>	RW	0
14	OBIE	<p>Out-of-Band Interrupt Enable (MMC cards only). This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: Out-of-Band interrupt detection disabled.</p> <p>0x1: Out-of-Band interrupt detection enabled.</p>	RW	0
13	OBIP	<p>Out-of-Band Interrupt Polarity (MMC cards only). This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: active high level.</p> <p>0x1: active low level.</p>	RW	0
12	CEATA	<p>CE-ATA control mode (MMC cards compliant with CE-ATA): By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features.</p> <p>0x0: Standard MMC/SD/SDIO mode.</p> <p>0x1: CE-ATA mode. Next commands are considered as CE-ATA commands.</p>	RW	0
11	CTPL	<p>Control Power for mmci_dat[1] line (MMC and SD cards): By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current.</p> <p>SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmci_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmci_dat[1] line and minimize the leakage current of the buffers.</p> <p>0x0: Disable all the input buffers outside of a transaction.</p> <p>0x1: Disable all the input buffers except the buffer of mmci_dat[1] outside of a transaction.</p>	RW	0
10:9	DVAL	<p>Debounce filter value (All cards) This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: 33 us debounce period.</p> <p>0x1: 231 us debounce period.</p>	RW	0x3

Bits	Field Name	Description	Type	Reset
		0x2: 1 ms debounce period. 0x3: 8.4 ms debounce period.		
8	WPP	Write protect polarity (SD and SDIO cards only) This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
7	CDP	Card detect polarity (All cards) This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level.	RW	0
6	MIT	MMC interrupt command (Only for MMC cards.) This bit must be set to 1, when the next write access to the command register (MMCi.MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled	RW	0
5	DW8	8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 0x0: 1-bit or 4-bit Data width (mmci_dat[0] or mmci_dat[3:0] used, MMC, SD cards) 0x1: 8-bit Data width (mmci_dat[7:0] used, MMC cards)	RW	0
4	MODE	Mode select (All cards) These bits select the functional mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the MMCi.MMCHS_CMD register. 0x1: SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.	RW	0
3	STR	Stream command (Only for MMC cards). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer. 0x1: Stream oriented data transfer.	RW	0

Bits	Field Name	Description	Type	Reset
2	HR	<p>Broadcast host response (Only for MMC cards). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. To have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1.</p> <p>When MMCi.MMCHS_CON[12] CEATA bit is set to 1 and MMCi.MMCHS_ARG set to 0x00000000, when writing 0x00000000 into MMCi.MMCHS_CMD register, the host controller performs a 'command completion signal disable' token (i.e. <code>mmci_cmd</code> line held to '0' during 47 cycles followed by a 1).</p> <p>0x0: The host does not generate a 48-bit response instead of a command.</p> <p>0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p>	RW	0
1	INIT	<p>Send initialization stream (All cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the <code>mmci_cmd</code> line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCi.MMCHS_SYSCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms.</p> <p>Note: in this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. MMCi.MMCHS_STAT[0] CC bit can be polled.</p> <p>0x0: The host does not send an initialization sequence.</p> <p>0x1: The host sends an initialization sequence.</p>	RW	0
0	OD	<p>Card open drain mode (Only for MMC cards). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state.</p> <p>It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCi.MMCHS_CON[2] HR bit)</p> <p>0x0: No Open Drain</p> <p>0x1: Open Drain or Broadcast host response</p>	RW	0

	0x480B 4104		MMCHS2
Description	Transfer Length Configuration register This register shall be used for any card.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NBLK																Reserved						BLEN									

Bits	Field Name	Description	Type	Reset
31:16	NBLK	<p>Blocks count for current transfer. This register is enabled when Block count Enable (MMCI.MMCHS_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count.</p> <p>0x0: Stop count 0x1: 1 block 0x2: 2 blocks 0xFFFF: 65535 blocks</p>	RW	0x0000
15:11	Reserved	Reserved bit field. Do not write any value	R	0x00
10:0	BLEN	<p>Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCI.MMCHS_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched.</p> <p>0x0: No data transfer 0x1: 1 byte block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0x1FF: 511 bytes block length 0x200: 512 bytes block length 0x3FF: 1023 bytes block length 0x400: 1024 bytes block length</p>	RW	0x000

Table 24-51. MMCHS_CMD

Address Offset	0x10C		
Physical Address	0x4809 C10C	Instance	MMCHS1
	0x480A D10C		MMCHS3
	0x480B 410C		MMCHS2
Description	Command and transfer mode register MMCi.MMCHS_CMD[31:16] = the command register MMCi.MMCHS_CMD[15:0] = the transfer mode. This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCi.MMCHS_CMD[15:0] registers during data transfer has no effect. This register shall be used for any card.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	INDX							CMD_TYPE	DP	CICE	CCCE	Reserved	RSP_TYPE	Reserved										MSBS	DDIR	Reserved	ACEN	BCE	DE		

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29:24	INDX	Command index Binary encoded value from 0 to 63 specifying the command number send to card 0x0: CMD0 or ACMD0	RW	0x00

Bits	Field Name	Description	Type	Reset
		0x1: CMD1 or ACMD1 0x3F: CMD63 or ACMD63		
23:22	CMD_TYPE	Command type. This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 0b00 for all other commands. 0x0: Others Commands 0x1: Upon CMD52 "Bus Suspend" operation 0x2: Upon CMD52 "Function Select" operation 0x3: Upon CMD12 or CMD52 "I/O Abort" command	RW	0x0
21	DP	Data present select. This register indicates that data is present and mmci_dat line shall be used. It must be set to 0 in the following conditions: - Command using only mmci_cmd line - Command with no data transfer but using busy signal on mmci_dat[0] - Resume command 0x0: Command with no data transfer 0x1: Command with data transfer	RW	0
20	CICE	Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCi.MMCHS_STAT[19] CIE bit set to 1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable	RW	0
19	CCCE	Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCi.MMCHS_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable	RW	0
18	Reserved	Reserved bit field. Do not write any value.	R	0
17:16	RSP_TYPE	Response type. This bits defines the response type of the command. 0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response	RW	0x0
15:6	Reserved	Reserved bit field. Do not write any value.	R	0x000
5	MSBS	Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMcI.MMCHS_BLK[31:16] NBLK bits. 0x1: Multi block. When Block Count is disabled (MMCi.MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCi.MMCHS_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer.	RW	0
4	DDIR	Data transfer Direction. Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host)	RW	0

Bits	Field Name	Description	Type	Reset
3	Reserved	Reserved bit field. Do not write any value.	R	0
2	ACEN	Auto CMD12 Enable. (SDIO does not support this feature.) When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. For CE-ATA commands (MMCi.MMCHS_CON[12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated. 0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.	RW	0
1	BCE	Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK bits). When Block Count is disabled (MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks	RW	0
0	DE	DMA Enable. This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable	RW	0

Description	<p>Data Register</p> <p>This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.</p> <p>Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad</p>

Description	Present state register. The Host can get status of the Host Controller from this 32-bit read only register.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								CLEV	DLEV			Reserved	Reserved	Reserved	Reserved					BRE	BWE	RTA	WTA	Reserved				DLA	DATI	CMDI	

Bits	Field Name	Description	Type	Reset
31:25	Reserved	Reserved bit field. Do not write any value.	R	0x00
24	CLEV	mmci_cmd line signal level. This status is used to check the mmci_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmci_cmd line level at that time. Read 0x0: The mmci_cmd line level is 0. Read 0x1: The mmci_cmd line level is 1.	R	-
23:20	DLEV	mmci_dat[3:0] line signal level mmci_dat[3] => bit 23 mmci_dat[2] => bit 22 mmci_dat[1] => bit 21 mmci_dat[0] => bit 20 This status is used to check mmci_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmci_dat[0]. The value of these registers after reset depends on the mmci_dat lines level at that time.	R	0x-
19	Reserved	Reserved bit field. Do not write any value	R	0
18	Reserved	Reserved bit field. Do not write any value This bit is not affected by soft reset.	R	1
17:16	Reserved	Reserved bit field. Do not write any value The value of these bits after soft reset is 0x0. These bits will be automatically set to 0x3 after debounce time. Debounce time is fixed to 256 x32 kHz clock cycles.	R	00
15:12	Reserved	Reserved bit field. Do not write any value	R	0x0
11	BRE	Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCI.MMCHS_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCI.MMCHS_STAT[5] BRR bit). Read 0x0: Read BLEN bytes disable Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.	R	0
10	BWE	Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data. Read 0x0: There is no room left in the buffer to write BLEN bytes of data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data.	R	0

Bits	Field Name	Description	Type	Reset
9	RTA	<p>Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Read data transfer on going.</p>	R	0
8	WTA	<p>Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCi.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Write data transfer on going.</p>	R	0
7:3	Reserved	Reserved bit field. Do not write any value	R	0x00
2	DLA	<p>mmci_dat line active. This status bit indicates whether one of the mmci_dat line is in use. In the case of read transactions (card to host): This bit is set to 1 after the end bit of read command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card): This bit is set to 1 after the end bit of write command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x0: mmci_dat Line inactive Read 0x1: mmci_dat Line active</p>	R	0
1	DATI	<p>Command inhibit (mmci_dat). This status bit is generated if either mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or Read transfer is active (MMCi.MMCHS_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command. A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCi.MMCHS_STAT[1] TC bit).</p> <p>Read 0x0: Issuing of command using the mmci_dat lines is allowed Read 0x1: Issuing of command using mmci_dat lines is not allowed</p>	R	0
0	CMDI	<p>Command inhibit(mmci_cmd). This status bit indicates that the mmci_cmd line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted. This bit is set to 0 in either the following cases: - After the end bit of the command response, excepted if there is a command conflict error (MMCi.MMCHS_STAT[17] CCRC bit or MMCi.MMCHS_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (MMCi.MMCHS_AC12[0] ACNE bit). - After the end bit of the command without response (MMCi.MMCHS_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (MMCi.MMCHS_STAT[19] CTO bit set to 1), this register is not automatically cleared.</p> <p>Read 0x0: Issuing of command using mmci_cmd line is allowed Read 0x1: Issuing of command using mmci_cmd line is not allowed</p>	R	0

Reserved				OBWE	REM	INS	IWE	Reserved				IBG	RWC	CR	SBGR	Reserved			SDVS		SDBP	Reserved				DTW	Reserved				

Bits	Field Name	Description	Type	Reset
31:28	Reserved	Reserved bit field. Do not write any value.	R	0x00
27	OBWE	Wake-up event enable for 'Out-of-Band' Interrupt. This bit enables wake-up events for 'Out-of-Band' assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when MMCi.MMCHS_CON[14] OBIE bit is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt. 0x1: Enable wakeup on 'Out-of-Band' Interrupt.	RW	0
26	REM	Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card removal. 0x1: Enable wakeup on card removal.	RW	0
25	INS	Wake-up event enable on SD card insertion This bit enables wake-up events for card insertion assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card insertion. 0x1: Enable wakeup on card insertion.	RW	0
24	IWE	Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (MMCi.MMCHS_IE[8] CIRQ_ENABLE bit). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt	RW	0
23:20	Reserved	Reserved bit field. Do not write any value	R	0x0

Bits	Field Name	Description	Type	Reset
19	IBG	<p>Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0.</p> <p>0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode</p>	RW	0
18	RWC	<p>Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmci_dat line.</p> <p>0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control</p>	RW	0
17	CR	<p>Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e. mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or transferring data (MMCi.MMCHS_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (MMCi.MMCHS_HCTL[16] SBGR bit =0) before setting this bit.</p> <p>0x0: No affect 0x1: transfer restart</p>	RW	0
16	SBGR	<p>Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCi.MMCHS_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCi.MMCHS_DATA).</p> <p>0x0: Transfer mode 0x1: Stop at block gap</p>	RW	0
15:12	Reserved	Reserved bit field. Do not write any value.	R	0x0
11:9	SDVS	<p>SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (MMCi.MMCHS_CAPA[26] VS18 bit, MMcI.MMCHS_CAPA[25] VS30 bit, MMcI.MMCHS_CAPA[24] VS33 bit) before starting a transfer.</p> <p>0x5: 1.8V (Typical) 0x6: 3.0V (Typical) 0x7: 3.3V (Typical)</p> <p>MMCHS2: This field must be set to 0x5. MMCHS3: This field must be set to 0x5.</p>	RW	0x0
8	SDBP	<p>SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (MMCi.MMCHS_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCi.MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCi.MMCHS_CAPA[VS*]).</p> <p>0x0: Power off 0x1: Power on</p>	RW	0
7:2	Reserved	Reserved bit field. Do not write any value.	R	0x00

Bits	Field Name	Description	Type	Reset
1	DTW	Data transfer width. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with <i>MMC standard specification 4.x</i> This register has no effect when the MMC 8-bit mode is selected (MMCi.MMCHS_CON[5] DW8 bit set to 1) For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (mmci_dat[0] used) 0x1: 4-bit Data width (mmci_dat[3:0] used)	RW	0
0	Reserved	Reserved bit field. Do not write any value.	R	0

Reserved				SRD	SRC	SRA	Reserved				DTO				CLKD				Reserved				CEN	ICS	ICE						

Bits	Field Name	Description	Type	Reset
31:27	Reserved	Reserved bit field. Do not write any value.	R	0x00
26	SRD	Software reset for mmci_dat line. This bit is set to 1 for reset and released to 0 when completed .mmci_dat finite state machine in both clock domain are also reset. Here below are the registers cleared by the MMCHS_SYSCTL[26] SRD bit: MMCi.MMCHS_DATA MMCi.MMCHS_PSTATE : BRE, BWE, RTA, WTA, DLA and DAT1 MMCi.MMCHS_HCTL : SBGR and CR MMCi.MMCHS_STAT : BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for mmci_dat line	RW	0

Bits	Field Name	Description	Type	Reset
25	SRC	Software reset for mmci_cmd line. This bit is set to 1 for reset and released to 0 when completed. mmci_cmd finite state machine in both clock domain are also reset. Here below the registers cleared by the MMCI.MMCHS_SYSCTL[25] SRC bit: MMCI.MMCHS_PSTATE: CMDI MMCI.MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for mmci_cmd line	RW	0
24	SRA	Software reset for all. This bit is set to 1 for reset , and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers. 0x0: Reset completed 0x1: Software reset for all the design	RW	0
23:20	Reserved	Reserved bit field. Do not write any value.	R	0x0
19:16	DTO	Data timeout counter value and busy timeout. This value determines the interval by which mmci_dat lines timeouts are detected. The host driver needs to set this bit field based on - the maximum read access time (NAC) (See the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCI.MMCHS_CAPA[5:0] TCF bits). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCI.MMCHS_STAT[20] DTO bit). The MMCI.MMCHS_SYSCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0x0: TCF x 2 ¹³ 0x1: TCF x 2 ¹⁴ 0xE: TCF x 2 ²⁷ 0xF: Reserved	RW	0x0
15:6	CLKD	Clock frequency select These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmci_clk pin of either the memory card (MMC, SD or SDIO). 0x0: Clock Ref bypass 0x1: Clock Ref bypass 0x2: Clock Ref / 2 0x3: Clock Ref / 3 0x3FF: Clock Ref / 1023	RW	0x000
5:3	Reserved	Reserved bit field. Do not write any value	R	0x0
2	CEN	Clock enable. This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCI.MMCHS_SYSCTL[1] ICS bit).	RW	0
1	ICS	Internal clock stable (status)This bit indicates either the internal clock is stable or not. Read 0x0: The internal clock is not stable. Read 0x1: The internal clock is stable after enabling the clock (MMCI.MMCHS_SYSCTL[0] ICE bit) or after changing the clock ratio (MMCI.MMCHS_SYSCTL[15:6] CLKD bits).	R	0

Bits	Field Name	Description	Type	Reset
0	ICE	Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0x0: The internal clock is stopped (very low power state). 0x1: The internal clock oscillates and can be automatically gated when MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) .	RW	0

Bits	Field Name	Description	Type	Reset
31:30	Reserved	Reserved bit field. Do not write any value	R	0x0
29	BADA	Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: - During a read access to the data register (MMCi.MMCHS_DATA) while buffer reads are not allowed (MMCi.MMCHS_PSTATE[11] BRE bit =0) - During a write access to the data register (MMCi.MMCHS_DATA) while buffer writes are not allowed (MMCi.MMCHS_PSTATE[10] BWE bit=0) Read 0x0: No Interrupt. Write 0x0: Status bit unchanged Read 0x1: Bad Access Write 0x1: Status is cleared	RW	0

Bits	Field Name	Description	Type	Reset
28	CERR	<p>Card error.</p> <p>This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCi.MMCHS_CSRE in set.</p> <p>There is no card error detection for autoCMD12 command. The host driver shall read MMCi.MMCHS_RSP76 register to detect error bits in the command response.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Card error</p> <p>Write 0x1: Status is cleared</p>	RW	0
27:25	Reserved	Reserved bit field. Do not write any value	R	0x0
24	ACE	<p>Auto CMD12 error.</p> <p>This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: AutoCMD12 error</p> <p>Write 0x1: Status is cleared</p>	RW	0
23	Reserved	Reserved bit field. Do not write any value	R	0
22	DEB	<p>Data End Bit error.</p> <p>This bit is set automatically when detecting a 0 at the end bit position of read data on mmci_dat line or at the end position of the CRC status in write mode.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data end bit error</p> <p>Write 0x1: Status is cleared</p>	RW	0
21	DCRC	<p>Data CRC Error.</p> <p>This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.</p> <p>Read 0x0: No Error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data CRC error</p> <p>Write 0x1: Status is cleared</p>	RW	0
20	DTO	<p>Data timeout error. This bit is set automatically according to the following conditions:</p> <ul style="list-style-type: none"> - Busy timeout for R1b, R5b response type. - Busy timeout after write CRC status. - Write CRC status timeout. - Read data timeout. <p>Read 0x0: No error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Time out</p> <p>Write 0x1: Status is cleared</p>	RW	0
19	CIE	<p>Command index error.</p> <p>This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (MMCi.MMCHS_CMD[20] CICE).</p> <p>Read 0x0: No error</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Command index error</p> <p>Write 0x1: Status is cleared</p>	RW	0

Bits	Field Name	Description	Type	Reset
18	CEB	<p>Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response.</p> <p>Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Command end bit error Write 0x1: Status is cleared</p>	RW	0
17	CCRC	<p>Command CRC Error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (MMCi.MMCHS_CMD[19] CCCE).</p> <p>Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Command CRC error Write 0x1: Status is cleared</p>	RW	0
16	CTO	<p>Command Timeout Error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.</p> <p>Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Time Out Write 0x1: Status is cleared</p>	RW	0
15	ERRI	<p>Error Interrupt. If any of the bits in the Error Interrupt Status register (MMCi.MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.</p> <p>Read 0x0: No Interrupt Read 0x1: Error interrupt event(s) occurred</p>	R	0
14:10	Reserved	Reserved bit field. Do not write any value.	R	0x00
9	OBI	<p>Out-Of-Band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when MMCi.MMCHS_CON[14] OBIE bit is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMCi.MMCHS_CON[13] OBIP bit. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.</p> <p>Read 0x0: No Out-Of-Band interrupt. Write 0x0: Status bit unchanged. Read 0x1: Interrupt Out-Of-Band occurs. Write 0x1: Status is cleared.</p>	R	0
8	CIRQ	<p>Card interrupt. This bit is only used for SD and SDIO cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives mmci_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting MMCi.MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCi.MMCHS_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt Read 0x1: Generate card interrupt</p>	R	0
7:6	Reserved	Reserved bit field. Do not write any value.	RW	00

Bits	Field Name	Description	Type	Reset
5	BRR	<p>Buffer read ready.</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the MMCi.MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it.</p> <p>Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
4	BWR	<p>Buffer write ready.</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCi.MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer.</p> <p>Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p>	RW	0
3	Reserved	Reserved bit field. Do not write any value	R	0
2	BGE	<p>Block gap event.</p> <p>When a stop at block gap is requested (MMCi.MMCHS_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the mmci_dat line active status (MMCi.MMCHS_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Transaction stopped at block gap</p> <p>Write 0x1: Status is cleared</p>	RW	0
1	TC	<p>Transfer completed.</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCi.MMCHS_HCTL[16] SBGR bit).</p> <p>This bit is also set when exiting a command in a busy state (if the command has a busy notification capability).</p> <p>In Read mode: This bit is automatically set on completion of a read transfer (MMCi.MMCHS_PSTATE[9] RTA bit).</p> <p>In write mode: This bit is set automatically on completion of the mmci_dat line use (MMCi.MMCHS_PSTATE[2] DLA bit).</p> <p>Read 0x0: No transfer complete</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data transfer complete</p> <p>Write 0x1: Status is cleared</p>	RW	0
0	CC	<p>Command complete.</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCi.MMCHS_PSTATE[0] CMDI bit)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCi.MMCHS_STAT[16] CTO bit) has higher priority than command complete (MMCi.MMCHS_STAT[0] CC bit).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p>	RW	0

Bits	Field Name	Description	Type	Reset
		Read 0x0: No Command complete		
		Write 0x0: Status bit unchanged		
		Read 0x1: Command complete		
		Write 0x1: Status is cleared

Table 24-75. MMCHS_AC12

Address Offset	0x13C			
Physical Address	0x4809 C13C	Instance	MMCHS1	
	0x480A D13C		MMCHS3	
	0x480B 413C		MMCHS2	
Description	Auto CMD12 Error Status Register. The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this MMChS.AC12 register when an Auto CMD12 Error interrupt occurs. This register is valid only when Auto CMD12 is enabled (MMChS.ACEN bit) and Auto CMD12Error (MMChS.STAT[24] ACE bit) is set to 1. Note: These bits are automatically reset when starting a new adtc command with data.			
Type	R			

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved																CNI	Reserved	ACIE	ACEB	ACCE	ACTO	ACNE									

Bits	Field Name	Description	Type	Reset
31:8	Reserved	Reserved bit field. Do not write any value.	R	0x0
7	CNI	Command not issue by Auto CMD12 error. If this bit is set to 1, it means that pending command is not executed due to Auto CMD12 error: ACEB, ACCE, ACTO or ACNE. Read 0x0: Not error Read 0x1: Command not issued	R	0
6:5	Reserved	Reserved bit field. Do not write any value.	R	0x0
4	ACIE	Auto CMD12 index error. This bit is a set to 1 when response index differs from corresponding command auto CMD12 index previously emitted. This bit depends on the command index check enable (MMChS.ACEN bit). Read 0x0: No error Read 0x1: Auto CMD12 Index Error	R	0
3	ACEB	Auto CMD12 end bit error. This bit is set to 1 when detecting a 0 at the end bit position of auto CMD12 command response. Read 0x0: No error Read 0x1: AutoCMD12 End bit Error	R	0

Bits	Field Name	Description	Type	Reset
2	ACCE	Auto CMD12 CRC error. This bit is automatically set to 1 when a CRC7 error is detected in the auto CMD12 command response depending on the enable in the MMCI.MMCHS_CMD[19] CCCE bit. Read 0x0: No error Read 0x1: Auto CMD12 CRC Error	R	0
1	ACTO	Auto CMD12 timeout error. This bit is set to 1 if no response is received within 64 clock cycles from the end bit of the auto CMD12 command. Read 0x0: No error Read 0x1: Auto CMD12 Time Out	R	0
0	ACNE	Auto CMD12 not executed. This bit is set to 1 if multiple block data transfer command has started and if an error occurs in command before Auto CMD12 starts. Read 0x0: Auto CMD12 Executed Read 0x1: Auto CMD12 Not Executed	R	0

Description	Capabilities register. This register lists the capabilities of the MMC/SD/SDIO host controller.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				VS18	VS30	VS33	SRS	DS	HSS	Reserved			MBL	Reserved		BCF				TCU	Reserved	TCF									

Bits	Field Name	Description	Type	Reset
31:27	Reserved	Reserved bit field. Do not write any value.	R	0x00
26	VS18	Voltage support 1.8V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCI_RESET signal). Read 0x0: 1.8 V Not Supported Write 0x0: 1.8 V Not supported Read 0x1: 1.8 V Supported Write 0x1: 1.8 V Supported MMCHS1, 2 and 3: This bit must be set to 1.	RW	0
25	VS30	Voltage support 3.0V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCI_RESET signal). Read 0x0: 3.0 V Not Supported Write 0x0: 3.0 V Not supported Read 0x1: 3.0 V Supported	RW	0

Bits	Field Name	Description	Type	Reset
		Write 0x1: 3.0 V Supported MMCHS1: This bit must be set to 1. MMCHS2 and 3: This bit must be left to 0.		
24	VS33	Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal) Read 0x0: 3.3 V Not Supported Write 0x0: 3.3 V Not supported Read 0x1: 3.3 V Supported Write 0x1: 3.3 V Supported MMCHS1, 2 and 3: This bit must be left to 0.	RW	0
23	SRS	Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x0: The Host controller does not Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality.	R	1
22	DS	DMA support. This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA Not Supported Read 0x1: DMA Supported	R	1
21	HSS	High speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. Read 0x0: High Speed Not Supported Read 0x1: High Speed Supported	R	1
20:18	Reserved	Reserved bit field. Do not write any value.	R	0x0
17:16	MBL	Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes	R	0x1
15:14	Reserved	Reserved bit field. Do not write any value	R	0x0
13:8	BCF	Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See Chapter 3, Power, Reset, and Clock Management , for more information on the value of FUNC_96M_CLK clock signal.	R	0x00
7	TCU	Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: kHz Read 0x1: MHz	R	1
6	Reserved	Reserved. This bit is initialized to zero, and writes to it are ignored.	R	0
5:0	TCF	Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. Note: You can have the timeout clock frequency by dividing FUNC_96M_CLK by the value of the MMCi.MMCHS_SYCTL[15:6] CLKD bit field.	R	0x00

General-Purpose Interface

This chapter describes the general-purpose interface for the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

25.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 x 32) pins.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode when external events are detected. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode when external events are detected

These modules do not include pad control (pullup/down control, open-drain feature). For more information, see [Chapter 13, System Control Module](#).

25.1.1 Global Features

GPIOs include the following global features:

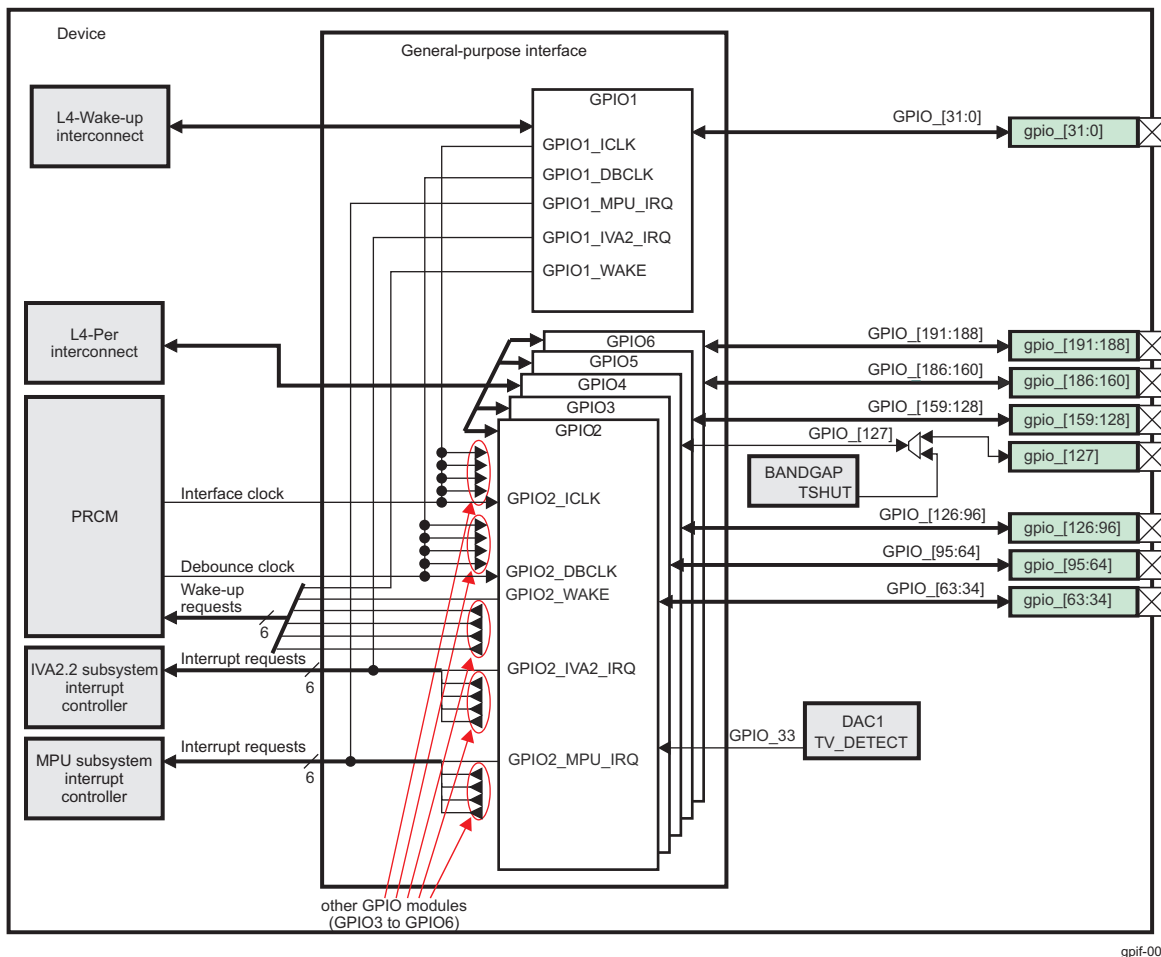

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the imaging video and audio accelerator (IVA2.2) and the microprocessor unit (MPU) subsystems. One of these interrupts is mapped on the IVA2.2 subsystem interrupt controller (INTC) and the other on the MPU subsystem INTC.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

[Figure 25-1](#) shows an overview of the general-purpose interface.

Figure 25-1. General-Purpose Interface Overview

gpif-001

Each channel in GPIOs has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the level 4 (L4) interconnect.
- The input line can be fed to GPIO through an optional and configurable debounce cell. (The debouncing time value is global for all ports of one GPIO module, so up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) used can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: Rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQENABLE1
- GPIOi.GPIO_IRQENABLE2
- GPIOi.GPIO_WAKEUPENABLE

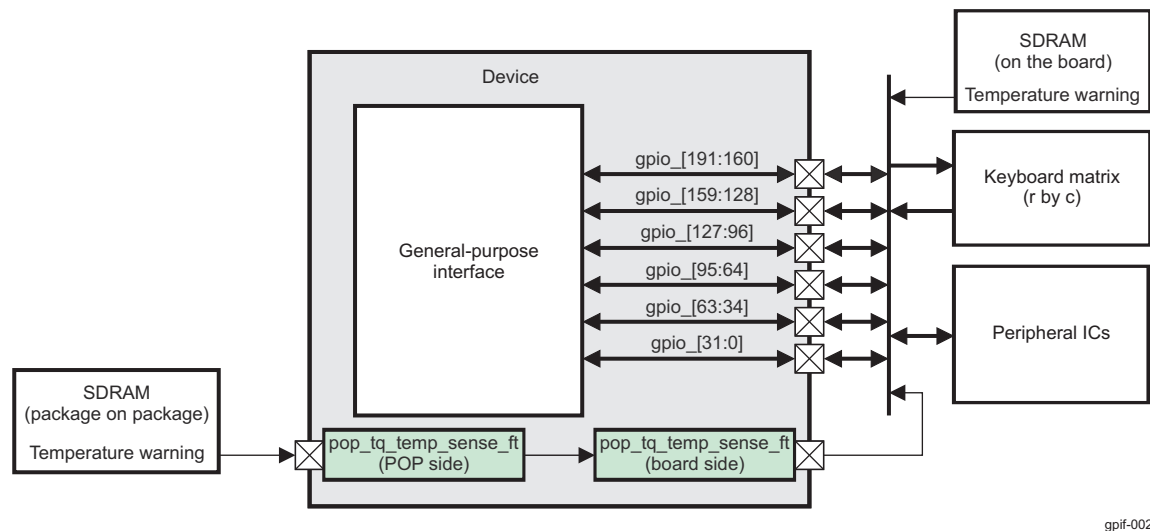

For these registers, the modules implement the set-and-clear protocol register update (see [Section 25.5.2, Set and Clear Instructions](#)).

25.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, GPIO controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 25-2 shows a typical application using the general-purpose interface.

Figure 25-2. General-Purpose Interface Typical Application System Overview

NOTE: Temperature Sensing

Most memories provide a temperature sensor to control the auto-refresh duty cycle. The device monitors the temperature of the external memory using the `pop_tq_temp_sense_ft` ball and a GPIO input. To do this, `pop_tq_temp_sense_ft` is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

Due to buffer strength, an external serial resistor must be connected to the balls corresponding to `gpio_120` to `gpio_129` pads.

GPIO multiplexed on these pads should only be used with special electrical attention, and if no other solutions are possible for their considered application.

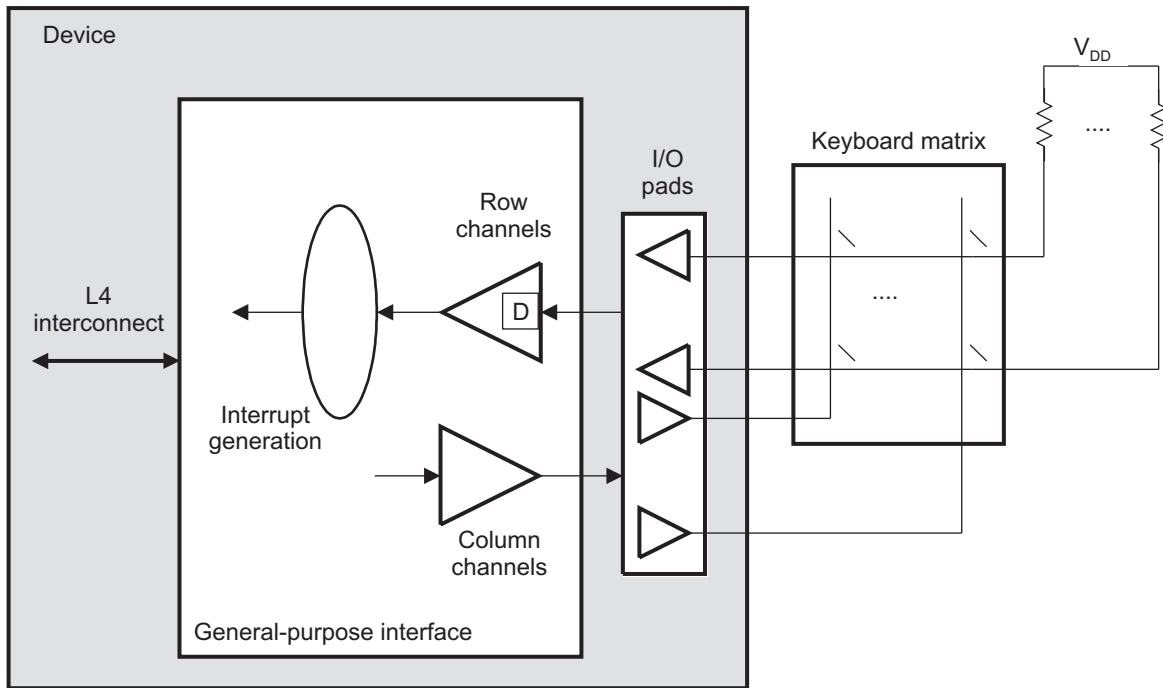

They are not multiplexed on standard 1.8-V I/O cell buffers but specific dual-voltage USIM/MMC-compliant buffers with nonstandard voltage domains, power-up sequences, power states, and controls/configurations.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

25.2.1 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. You can dedicate channels based on the keyboard matrix size ($r \times c$). Figure 25-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low-level.

Figure 25-3. General-Purpose Interface Used as a Keyboard Interface

gpif-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low-level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see [Section 25.5.3, Interrupt and Wakeup](#)).

When the keyboard interrupt is received, the processor (the MPU and/or IVA2.2 subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

25.2.2 General-Purpose Interface Functional Interfaces

25.2.2.1 General-Purpose Interface Pins

[Table 25-1](#) lists the interface pins of the general-purpose interface.

Table 25-1. I/O Pin Description

Signal Name	I/O ⁽¹⁾ ⁽²⁾	Description ⁽³⁾ ⁽²⁾	Reset Value
gpio_[31:0]	I/O	GPIO in configuration mode 4.	HiZ
gpio_[186:34]	I/O	GPIO in configuration mode 4.	HiZ
gpio_[191:188]	I/O	GPIO in configuration mode 4.	HiZ

⁽¹⁾ I = Input; O = Output

⁽²⁾ Some of the pins have special or restricted use. For more information, see [Table 25-5](#).

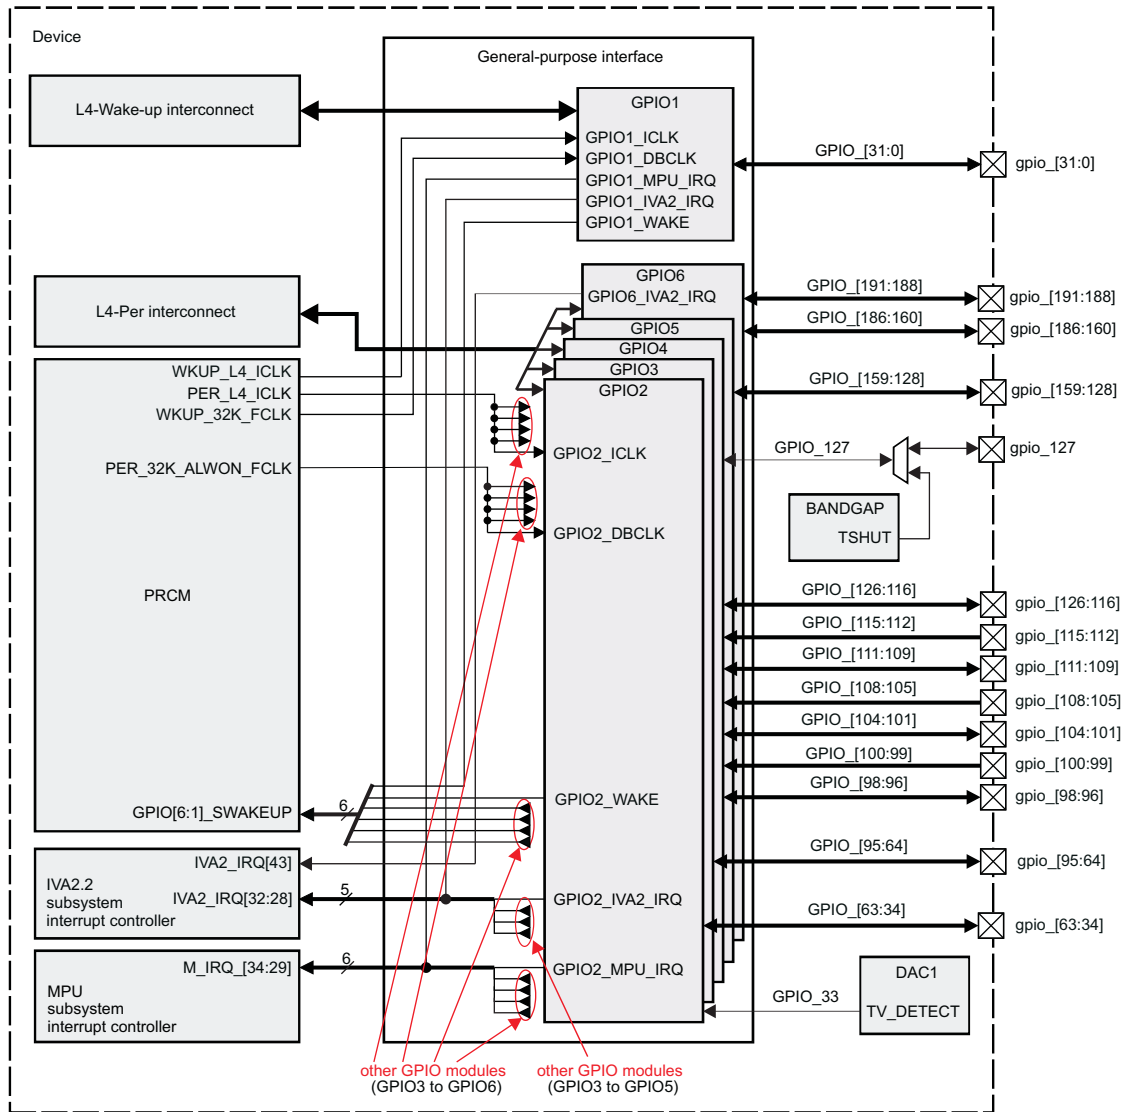

⁽³⁾ For more information about pin configuration modes, see [Chapter 13, System Control Module](#).

25.3 General-Purpose Interface Integration

25.3.1 Description

Figure 25-4 highlights the general-purpose interface integration in the device.

Figure 25-4. General-Purpose Interface Integration

gpif-004

25.3.1.1 Clocking, Reset, and Power-Management Scheme

25.3.1.1.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-KHz debounce clock, GPIOi_DBCLK, (where i = 1, 2, 3, 4, 5, and 6, with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay. For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where i = 2 to 6) bit PRCM.CM_FCLKEN_PER (0: Disables, 1: Enables the clock). For GPIO1, this clock is controlled by the EN_GPIO1 bit PRCM.CM_FCLKEN_WKUP[3] (0: Disables, 1: Enables the clock) for GPIO1.

- Interface clock: The interface clock, GPIOi_ICLK (where i = 1, 2, 3, 4, 5, and 6), comes from the PRCM module and is used throughout GPIO (except within the debounce cell logic). The interface clock clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity. For GPIO1, this clock is controlled by the EN_GPIO1 bit PRCM.CM_ICLKEN_WKUP[3] (0: Disabled, 1: Enabled the clock) and the AUTO_GPIO1 bit PRCM.CM_AUTOIDLE_WKUP[3] (enables/disables automatic control of the interface clock). For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where i = 2 to 6) bit PRCM.CM_ICLKEN_PER (0: Disables, 1: Enables the clock) and the AUTO_GPIOi (where i = 2 to 6) bit PRCM.CM_AUTOIDLE_PER (enables/disables automatic control of the interface clock). [Table 25-2](#) describes the GPIO clocks.

Table 25-2. Clocks

Attribute	Frequency	Name	Mapping	Comments
Debounce clock	32 KHz	GPIOi_DBCLK, where i = 2 to 6	PER_32K_ALWON_F CLK	Source is PRCM module.
		GPIO1_DBCLK	WKUP_32K_CLK	
Interface clock	Depends on PRCM registers settings	GPIOi_ICLK, where i = 2 to 6	PER_L4_ICLK	
		GPIO1_ICLK	WKUP_L4_ICLK	

25.3.1.1.2 Reset

The general-purpose interface can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: GPIO2 to GPIO6 are attached to the PER_RST reset domain. GPIO1 is attached to the WKUP_RST reset domain. The hardware reset has a global reset action on GPIOs of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low-level). In each GPIO module, the RESETDONE bit GPIOi.GPIO_SYSSTATUS[0] monitors the internal reset status; it is set when the reset completes. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).
- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules. Writing 1 to the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6) resets the module. The bit value of 1 remains until the reset completes. When the software reset completes, the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. This bit is set to 1 when the software reset completes.

25.3.1.1.3 Power Domain

GPIO1 is attached to the WKUP power domain (see [Chapter 3, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. GPIO2 to GPIO6 are attached to the PER power domain (see [Chapter 3, Power, Reset, and Clock Management](#)). The PER power domain is not active continuously.

25.3.1.1.4 Power Management

25.3.1.1.4.1 Idle Scheme

To save dynamic consumption, an efficient idle scheme is based on:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring a complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_SWAKEUP, where i = 1, 2, 3, 4, 5, and 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 25.3.1.2, Hardware Requests](#)).

25.3.1.1.4.2 Operating Modes

The following four operating modes are defined for the modules:

- **Active mode:** The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- **Idle mode:** Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.

- **Inactive mode:** The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- **Disabled mode:** The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Chapter 3, Power, Reset, and Clock Management](#)) through sideband signals (see [Section 25.3.1.1.4.3, System Power Management and Wake-Up](#)).

The disabled mode is set by software through a dedicated configuration bit, the GPIOi.GPIO_CTRL[0] DISABLEMODULE bit (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

25.3.1.1.4.3 System Power Management and Wake-Up

The PRCM module can require GPIOs to be idled for power saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Figure 25-4](#) and [Section 25.3.1.2, Hardware Requests](#)): One per GPIO module. The general-purpose interface allows GPIOs to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field.

The idle acknowledge depends on the configuration and activity of each GPIO module:

- **Smart-idle mode (recommended)**
When GPIO is configured in smart-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field [10]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: The corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: the PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or the PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), GPIO checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt-status bits are cleared); and there is no access to the GPIO.GPIO_DEBOUNCINGTIME register pending synchronization.

The idle acknowledge is then asserted and the module enters into idle mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

When in idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

When the expected transition occurs on an enabled GPIO input pin, GPIO exits from idle mode, if the

GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit is set to 1 (wake-up capability enabled), and the corresponding bit in the PRCM.PM_WKEN_PER register is also set to 1 for the GPIO2 to GPIO6, and/or the PRCM.PM_WKEN_WKUP[3] EN_GPIO1 bit is also set to 1 for GPIO1.

- Force-idle mode

When GPIO is configured in force-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field [00]) and receives an idle request from the PRCM module for GPIO2 to GPIO6: The corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0, or the corresponding bit in PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: the PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, the PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or the PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and the L4 interface clock idle transitions), GPIO waits unconditionally for an active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When GPIO is configured in no-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field [01]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: The corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: the PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), GPIO does not go to idle mode and the idle acknowledge is never sent.

NOTE: The GPIO2 to GPIO6 idle state can be checked by reading the corresponding status bits in the PRCM.CM_IDLEST_PER register (0: Active; 1: Idle) and is idle only when GPIO2 to GPIO6 are configured in smart-idle mode and have asserted their idle acknowledge.

The GPIO1 idle state can be checked by the PRCM.CM_IDLEST_WKUP[3] ST_GPIO1 bit (0: Idle, 1: active) and is idle only when GPIO1 is configured in smart-idle mode and has asserted its idle acknowledge.

GPIO2 to GPIO6 wake-up status can be checked by accessing the corresponding bits in the PRCM.PM_WKST_PER register (read 0: No wakeup occurred; read 1: Wakeup occurred; write 1: Status bit reset).

The GPIO1 wake-up status can also be checked by the PRCM.PM_WKST_WKUP[3] ST_GPIO1 bit (read 0: No wake-up occurred; read 1: Wakeup occurred; write 1: Status bit reset).

25.3.1.1.4.4 Module Power Saving

GPIO has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: The clock for the input data sample logic can be gated when the data in the register is not accessed.
- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in synchronous events detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, the corresponding clock is gated off (see [Section 25.5.1, Power Saving by Grouping the Edge/Level Detection](#)). All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1] GATINGRATIO bit field; it can take the values 1 (b00), 2 (0b01), 4 (b10), or 8 (0b11). The interface clock is enabled for this logic one cycle every N cycles. When N equals 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic runs at a frequency equal to

the interface clock frequency divided by N.

- Inactive mode: All internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

Each 8-input group of GPIO has a clock-enable signal that can be enabled or disabled depending on the edge/level detection register setting. If a group requires no detection, then the corresponding clock is gated.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

25.3.1.2 Hardware Requests

25.3.1.2.1 Interrupt Requests

All interrupt sources (the 32 input GPIO channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt-enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

- Synchronous interrupt request line 1 is mapped on the MPU INTC.
- Synchronous interrupt request line 2 is mapped on the IVA2.2 INTC.

Table 25-3 lists the interrupt lines that are driven out from the general-purpose interface to the MPU INTC and the IVA2.2 INTC.

Table 25-3. Interrupts

Name	Mapping	Comments
GPIO1		
GPIO1_MPU_IRQ	M_IRQ_29	Destination is the MPU INTC.
GPIO1_IVA2_IRQ	IVA2_IRQ[28]	Destination is the IVA2.2 INTC.
GPIO2		
GPIO2_MPU_IRQ	M_IRQ_30	Destination is the MPU INTC.
GPIO2_IVA2_IRQ	IVA2_IRQ[29]	Destination is the IVA2.2 INTC.
GPIO3		
GPIO3_MPU_IRQ	M_IRQ_31	Destination is the MPU INTC.
GPIO3_IVA2_IRQ	IVA2_IRQ[30]	Destination is the IVA2.2 INTC.
GPIO4		
GPIO4_MPU_IRQ	M_IRQ_32	Destination is the MPU INTC.
GPIO4_IVA2_IRQ	IVA2_IRQ[31]	Destination is the IVA2.2 INTC.
GPIO5		
GPIO5_MPU_IRQ	M_IRQ_33	Destination is the MPU INTC.
GPIO5_IVA2_IRQ	IVA2_IRQ[32]	Destination is the IVA2.2 INTC.
GPIO6		
GPIO6_MPU_IRQ	M_IRQ_34	Destination is the MPU INTC.
GPIO6_IVA2_IRQ	IVA2_IRQ[43]	Destination is the IVA2.2 INTC.

25.3.1.2.1.1 Wake-Up Generation

GPIO1 of the general-purpose interface is attached to the WKUP power domain (see [Chapter 3, Power, Reset, and Clock Management](#)) and can wake up the system.

NOTE: GPIO2 to GPIO6 modules belong to the PER power domain and thus have wake-up system capability only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

NOTE: Only gpio_1, gpio_9, gpio_10, gpio_11, gpio_30, and gpio_31 can be used to generate a direct wake-up event. The other GPIO1 pins cannot be used to generate a direct wake-up event, because they are connected to the device I/O pad logic in the CORE power domain (VDD2). When the CORE power domain is OFF, the VDD2-supplied I/O pins of GPIO1 cannot generate a wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_WAKEUPENABLE register (where i = 1, 2, 3, 4, 5, and 6).

CAUTION

The wake-up capabilities of GPIO2 to GPIO6 are operational only when the PER power domain is active.

[Table 25-4](#) shows the wake-up signals mapping.

Table 25-4. Wake-Up Signals

Name	Mapping	Comments
GPIOi_WAKE	GPIOi_SWAKEUP	Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module.

[Table 25-5](#) describes the GPIO channels.

GPIO6				
[26:0]	I/O	gpio_[186:160]	Yes ⁽³⁾	GPIO ⁽²⁾
[27]	I	-	No	Not available on external balls. Read value is always 0.
[31:28]	I/O	gpio_[191:188]	Yes ⁽⁵⁾	GPIO ⁽⁶⁾

⁽⁴⁾ All configuration modes except configuration mode 4. See [Chapter 13, System Control Module](#).

⁽⁵⁾ Only when the PER power domain is active

⁽⁶⁾ Configuration mode 4. See [Chapter 13, System Control Module](#).

NOTE: The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is high during normal operation and goes low during a thermal shutdown event. When channel 31 of GPIO4 is not connected to a ball of the device (the corresponding pin is configured in a mode different from the configuration mode 4; for more information about pin configuration see [Chapter 13, System Control Module](#)), TSHUT is connected to channel 31 of GPIO4, and an interrupt can be generated when a high-to-low transition occurs on TSHUT whether or not the interrupt generation for channel 31 of GPIO4 is correctly configured.

25.4 General-Purpose Interface Functional Description

Figure 25-5 shows the general-purpose interface description.

Figure 25-5. General-Purpose Interface Description

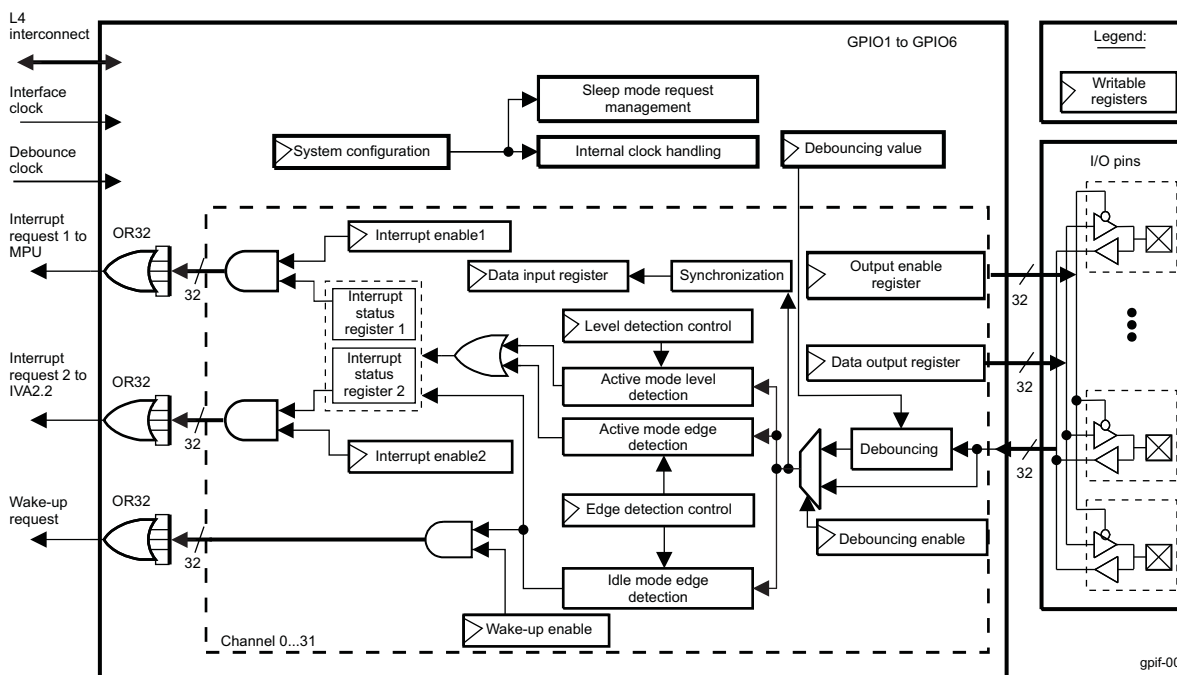

Figure 25-5 details GPIOs in the general-purpose interface block diagram with their configuration registers and their main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO; the synchronous interrupt request lines 1 and 2 are active based on their respective interrupt-enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2). See Figure 25-6.

Figure 25-6. Synchronous Path

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO; the asynchronous wake-up request line is active based on the wakeup-enable register. See Figure 25-7.

Figure 25-7. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode).

25.4.1 Operational Description

25.4.1.1 Interrupt and Wake-Up Features

25.4.1.1.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance). The 12 interrupt signals are GPIOi_MPU_IRQ (used by the MPU subsystem) and GPIOi_IVA2_IRQ (used by the IVA2.2 subsystem), where $i = 1, 2, 3, 4, 5,$ and 6 .

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the IVA2.2 subsystem and the MPU subsystem. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) and interrupt-status (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) registers. The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt-status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt-status registers independent of the content of the interrupt-enable registers.

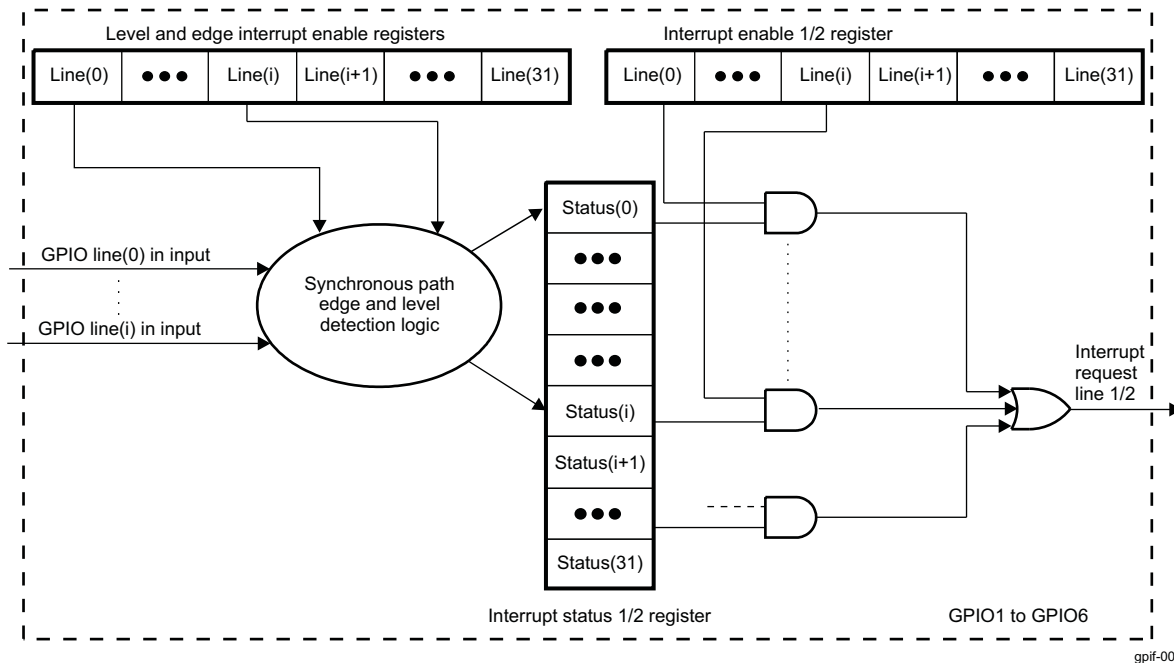

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 25.5.3, *Interrupt and Wakeup*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 25.3.1.1.4.4, *Module Power Saving*). When an event matches the programmed settings (see Section 25.5.3, *Interrupt and Wakeup*), the corresponding bit in the interrupt-status register is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals N times the interface clock period; see Section 25.3.1.1.4.4, *Module Power Saving*). This minimum pulse width must be met before and after any expected level transition detection. For level detection, the selected level must be stable for at least two times the internally-gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles plus one interface clock cycle when the debounce feature is not used.

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see Section 25.5.5, *Debouncing Time*) and is less than three internally gated interface clock cycles plus two interface clock cycle, plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the MPU INTC.
Synchronous interrupt request line 2 is mapped on the IVA2.2 INTC.
Figure 25-8 shows an overview of the interrupt request generation.

Figure 25-8. Interrupt Request Generation

gpif-007

25.4.1.1.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wakeup-enable register (`GPIOi.GPIO_WAKEUPENABLE`) selects the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt-status registers (`GPIOi.GPIO_IRQSTATUS1` and `GPIOi.GPIO_IRQSTATUS2`).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see [Section 25.5.3, Interrupt and Wakeup](#)), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (`GPIOi_SWAKEUP`, where $i = 1, 2, 3, 4, 5,$ and 6), if the wakeup-enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt-status registers (`GPIOi.GPIO_IRQSTATUS1` and `GPIOi.GPIO_IRQSTATUS2`). On the following internal clock cycle, the interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt-enable registers (`GPIOi.GPIO_IRQENABLE1` and `GPIOi.GPIO_IRQENABLE2`).

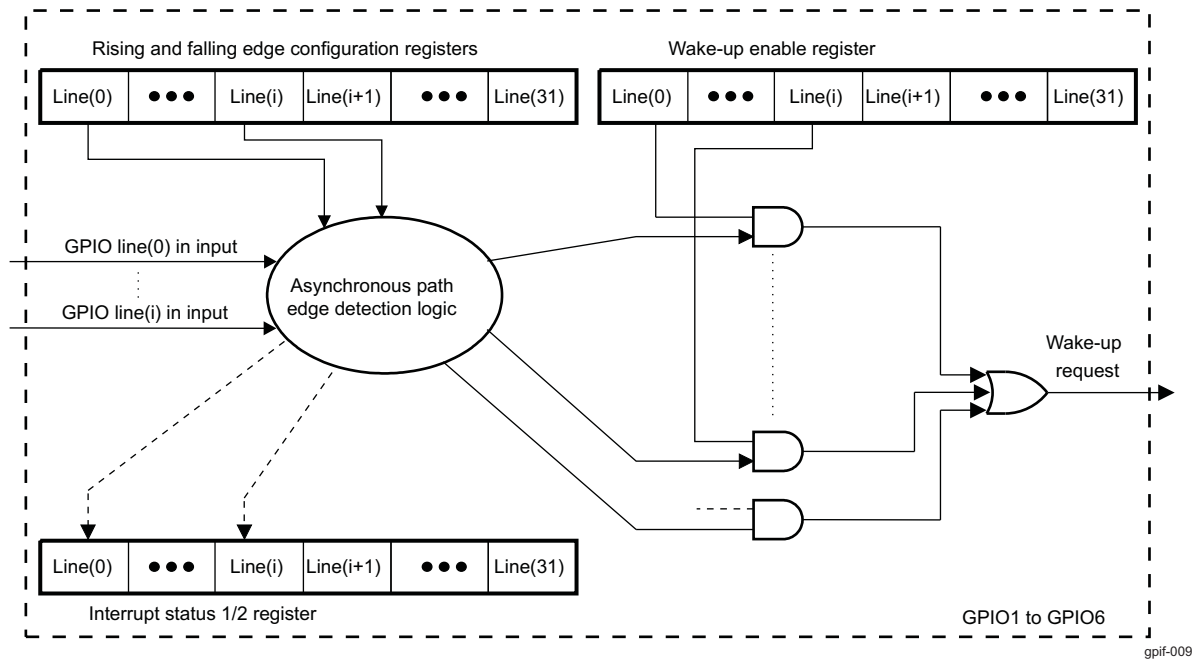

NOTE: When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The `GPIOi.GPIO_SYSCONFIG[2]` `ENAWAKEUP` bit enables or disables the GPIO wake-up feature globally. If the bit is 0, the wakeup-enable register (`GPIOi.GPIO_WAKEUPENABLE`) has no effect.

Figure 25-9 shows an overview of the wake-up request generation.

Figure 25-9. Wake-Up Request Generation

25.4.1.1.3 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or IVA2.2 subsystem in the device) receives an interrupt request issued by GPIO, it reads the corresponding interrupt-status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing 1 in the corresponding bit of the interrupt-status register. If there is still a pending interrupt request to serve (all bits in the interrupt-status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

25.5 General-Purpose Interface Basic Programming Model

25.5.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the following registers

- GPIOi.GPIO_LEVELDETECT0
- GPIOi.GPIO_LEVELDETECT1
- GPIOi.GPIO_RISINGDETECT
- GPIOi.GPIO_FALLINGDETECT

are set to 0x01 01 01 01, all clocks are active (power consumption is high). If any of these registers are set to 0x00 00 00 FF, only one clock is active (power saving).

NOTE: When the clocks are enabled by writing to the GPIOi.GPIO_LEVELDETECT0, GPIOi.GPIO_LEVELDETECT1, GPIOi.GPIO_RISINGDETECT, and GPIOi.GPIO_FALLINGDETECT registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock was started before and a new setting is performed, the following is recommended: First, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

25.5.2 Set and Clear Instructions

25.5.2.1 Description

GPIO implements the set-and-clear protocol register update for the GPIOi.GPIO_DATAOUT, GPIOi.GPIO_IRQENABLE1, GPIOi.GPIO_IRQENABLE2, and GPIOi.GPIO_WAKEUPENABLE registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

25.5.2.2 Clear Instruction

25.5.2.2.1 Clear Register Addresses

Clear interrupt-enable registers (GPIOi.GPIO_CLEARIRQENABLE1 and GPIOi.GPIO_CLEARIRQENABLE2).

A write operation in the clear interrupt-enable1 (or enable2) register clears the corresponding bit in the interrupt-enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt-enable1 (or enable2) register returns the value of the interrupt-enable1 (or enable2) register.

Clear wakeup-enable register (GPIOi.GPIO_CLEARWKUENA).

A write operation in the clear wakeup-enable register clears the corresponding bit in the wakeup-enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear wakeup-enable register returns the value of the wakeup-enable register.

Clear data output register (GPIOi.GPIO_CLEARDATAOUT).

A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data output register returns the value of the data output register.

25.5.2.2.2 Clear Instruction Example

Assume the data output register (or one of the interrupt/wakeup-enable registers) contains the binary value 0b0000 0001 0000 0001 and you want to clear bit 0.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data output register (or at the address of the clear interrupt/wakeup-enable register). After this write operation, a reading of the data output register (or the interrupt/wakeup-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 25-10 shows an example of a clear instruction.

Figure 25-10. Write @GPIO_CLEARDATAOUT Register Example

25.5.2.3 Set Instruction

25.5.2.3.1 Set Register Addresses

Set interrupt-enable registers (GPIOi.GPIO_SETIRQENABLE1 and GPIOi.GPIO_SETIRQENABLE2).

A write operation in the set interrupt-enable1 (or enable2) register sets the corresponding bit in the interrupt-enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt-enable1 (or enable2) register returns the value of the interrupt-enable1 (or enable2) register.

Set wakeup-enable register (GPIOi.GPIO_SETWKUENA).

A write operation in the set wakeup-enable register sets the corresponding bit in the wakeup-enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the set wakeup-enable register returns the value of the wakeup-enable register.

Set data output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data output register returns the value of the data output register.

25.5.2.3.2 Set Instruction Example

Assume the interrupt-enable1 (or enable2) register (or the data output register) contains the binary value, 0b0000 0001 0000 0000, and you want to set bits 15, 3, 2, and 1.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt-enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt-enable1 (or enable2) register (or the data output register) returns 0b1000 0001 0000 1110; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 25-11 shows an example of a set instruction.

Figure 25-11. Write @GPIO_SETIRQENABLEx Register Example

The set wakeup-enable register offers the same feature with the wakeup-enable register.

25.5.3 Interrupt and Wakeup

25.5.3.1 Involved Configuration Registers

- Interrupt-enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2)
The interrupt-enable1 (or interrupt-enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt-enable registers are programmed synchronously with the interface clock.
These registers can be accessed with direct read/write operations or using the alternate set-and-clear protocol register update feature. This feature enables to set or clear specific bits of these registers with a single write access to the corresponding set interrupt-enable1 (or interrupt-enable2) registers (or to the clear interrupt-enable1 [or interrupt-enable2] registers) address (see [Section 25.5.2, Set and Clear Instructions](#)).
- Wakeup-enable register (GPIOi.GPIO_WAKEUPENABLE)
The wakeup-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wakeup-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.
This register can be accessed with direct read/write operations or by using the alternate set-and-clear protocol register update feature. This feature allows setting or clearing specific bits of this register with a single write access to the set wakeup-enable register (or to the clear wakeup-enable register) address (see [Section 25.5.2, Set and Clear Instructions](#)).

NOTE: There must be a correlation between wakeup-enable and interrupt-enable registers. If a GPIO pin has a wakeup configured on it, it should also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the Idle mode, no interrupt is generated, thus the corresponding bit from the interrupt-status register is not cleared, and the module does not acknowledge a future IDLE request.

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2)
The interrupt-status1 (or interrupt-status2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line2) request (or the wake-up line).
When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt-status1 (or interrupt-status2) register.
If 0 is written to a bit in this register, the value remains unchanged. The interrupt-status1 (or interrupt-status2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and the corresponding bit in the interrupt-status1 and interrupt-status2 registers are set when GPIO is awake.

NOTE: The wake-up capabilities of GPIO2 to GPIO6 are operational only when the PER power domain is active.

25.5.3.2 Description

To generate interrupt request to a host processor (the MPU and/or digital signal processor [DSP] subsystem in the device) at a defined event (level or edge logic transition) occurring on a GPIO pin (interrupt source), the GPIO configuration registers must be programmed as follows:

1. The GPIO channel must be configured as input by the output-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the interrupt request must be selected in the low-level interrupt-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT0), and/or high-level interrupt-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT1), and/or rising-edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT), and/or falling edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT).

NOTE: Interrupt generation on both edges on one input is configured by setting the corresponding bit to 1 in the rising detect enabling register (GPIOi.GPIO_RISINGDETECT) and falling detect enabling register (GPIOi.GPIO_FALLINGDETECT) along with the interrupt-enable by setting the corresponding bit to 1 in one or both interrupt-enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

Simultaneous enabling of high-level and low-level detections for one given pin creates a constant-interrupt generator.

3. Interrupts from the GPIO channel must be enabled in the interrupt 1 enable register (write 1 to the corresponding bit of the GPIOi.GPIO_IRQENABLE1 register) and/or the interrupt 2 enable register (write 1 to the corresponding bit of the GPIOi.GPIO_IRQENABLE2 register).

To configure a GPIO module to send a wake-up request to the PRCM module at a defined event (logic transition) occurring on a GPIO pin (wake-up source), the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input by the output-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the wake-up request must be selected in the rising-edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT) and/or falling-edge interrupt/wakeup-enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT). The wake-up request can be generated only on edge transitions.
3. The GPIO channel must be enabled in the wakeup-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_WAKEUPENABLE register).
4. The wake-up request generation on the expected transition occurring on the GPIO input pins must enable the module (write 1 to the corresponding bit of the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit).

CAUTION

For each GPIO channel used, do not forget to configure the corresponding pad configuration registers in the system control module (SCM).

After servicing the interrupt, the status bit in the interrupt-status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) must be reset and the interrupt line released (by writing 1 in the corresponding bit of the interrupt-status register) before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

25.5.4 Data Input (Capture)/Output (Drive)

The output-enable register (GPIOi.GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module. Its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register (GPIOi.GPIO_CLEARDATAOUT) address (see [Section 25.5.2, Set and Clear Instructions](#)). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wakeup-enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt-enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers.

When configured as an input (the desired bit set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock (see [Section 25.5.2, Set and Clear Instructions](#)). When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the cycles required to synchronize and write data). If the application uses a pin as an input, the application must properly configure the wakeup-enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt-enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers to the interrupt and wake-up feature as needed.

25.5.5 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input in the output-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The debouncing time must be set in the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME).

The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in GPIO. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31μs long) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCVAL bit field value + 1) x 0.031 ms.

where GPIOi.GPIO_DEBOUNCINGTIME[7:0] bit field DEBOUNCVAL value is from 0 to 255.

3. The debouncing feature must be enabled in the debouncing-enable register (write 1 to the corresponding bit of the GPIOi.GPIO_DEBOUNCENABLE register).

25.6 General-Purpose Interface Register Manual

This section summarizes the hardware interface for the GPIO product. Each module instance within the design is shown, together with the module register map and bit definitions for each bit field.

Table 25-6 lists the base address and address space for GPIO instances.

Table 25-6. Instance Summary

Module Name	Base Address	Size
GPIO1	0x4831 0000	4KB
GPIO2	0x4905 0000	4KB
GPIO3	0x4905 2000	4KB
GPIO4	0x4905 4000	4KB
GPIO5	0x4905 6000	4KB
GPIO6	0x4905 8000	4KB

25.6.1 General-Purpose Interface Register Mapping Summary

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding). Access to registers is direct; no shadow registers are implemented.

Table 25-7 through Table 25-12 describe the GPIO register offset addresses.

Table 25-7. GPIO1 Register Summary

GPIO_SETWKUENA	RW	32	0x084	0x4905 8084
GPIO_CLEARDATAOUT	RW	32	0x090	0x4905 8090
GPIO_SETDATAOUT	RW	32	0x094	0x4905 8094

The write latency for all the R/W registers is immediate (with respect to the interface clock).

NOTE: When two write accesses in the GPIOi.GPIO_DEBOUNCINGTIME register are performed in less than two debounce clock cycles (32 kHz) plus four interface clock cycles, the first write access latency is immediate, but the second write access is acknowledged only after this interval ends.

In the register descriptions in this section, when one single register carries an individual configuration or setting for all the channels of the module, 1 bit in the register is dedicated to each channel. The bit and the corresponding channel are identified with the same number: Bit 0 refers to channel 0, bit 1 refers to channel 1, and so on, up to 31.

25.6.2 Register Descriptions

Table 25-13 through Table 25-63 describe the register bits.

Table 25-13. GPIO_REVISION

Address Offset	0x000	Instance	GPIO1
Physical Address	0x4831 0000		GPIO2
	0x4905 0000		GPIO3
	0x4905 2000		GPIO4
	0x4905 4000		GPIO5
	0x4905 6000		GPIO6
	0x4905 8000		
Description	This register contains the IP revision code.		
Type	R		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																GPIOREVISION															

Bits	Field Name	Description	Type	Reset
31:8	RESERVED	Read returns 0	R	0x000000
7:0	GPIOREVISION	IP revision [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1	R	See ⁽¹⁾

⁽¹⁾ TI internal data

Table 25-15. GPIO_SYSCONFIG

Address Offset	0x010		
Physical Address	0x4831 0010	Instance	GPIO1
	0x4905 0010		GPIO2
	0x4905 2010		GPIO3
	0x4905 4010		GPIO4
	0x4905 6010		GPIO5
	0x4905 8010		GPIO6
Description	This register controls the various parameters of the L4 interconnect.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																IDLEMODE		ENAWAKEUP	SOFTRESET	AUTOIDLE											

Bits	Field Name	Description	Type	Reset
31:5	RESERVED	Write 0s for future compatibility. Read returns 0	RW	0x00000000
4:3	IDLEMODE	Power Management, Req/Ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 0x3: Reserved do not use	RW	0x0
2	ENAWAKEUP	Wake-up capability enabled/disabled 0x0: Wakeup disable 0x1: Wakeup enable	RW	0x0
1	SOFTRESET	Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset	RW	0x0
0	AUTOIDLE	Internal interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic interface clock gating strategy is applied, based on the L4 interconnect activity	RW	0x0

Initialization

This chapter introduces the initialization steps in the general-purpose (GP) device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

Topic	Page
26.1 Initialization Overview	3524
26.2 Preinitialization	3525
26.3 Power, Clocks, and Reset Power-Up Sequence	3534
26.4 Device Initialization by ROM Code	3534
26.5 Wake-Up Booting by ROM Code	3590
26.6 Debug Configuration	3594

26.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the device from power on to firmware execution. An overview of the overall initialization process is given, including hardware- and software-related steps, a general overview of the boot ROM code operational requirements, and behavioral expectations.

26.1.1 Terminology

- **Bootstrap:** Initial software (SW) launched by the ROM code during the memory booting phase
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code in preflashing. It also programs an image in external memories.
- **GP device:** General-purpose device
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no software booting configuration is programmed.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM code:** The on-chip software in ROM that implements booting

26.1.2 Initialization Process

Figure 26-1 is an overview of the initialization process and its steps:

- Preinitialization
- Power/clock/reset ramp sequence
- Boot ROM
- Boot loader
- OS/application

Each step, up to OS/applications running, is explained in the following sections.

Figure 26-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require understanding of the process of configuring those system interface pins (balls on the device) that have software-configurable functionality. This configuration is an essential part of chip configuration and is application-dependent. This chapter refers to those pins and the associated configuration registers that are vital for correct device initialization.

26.2 Preinitialization

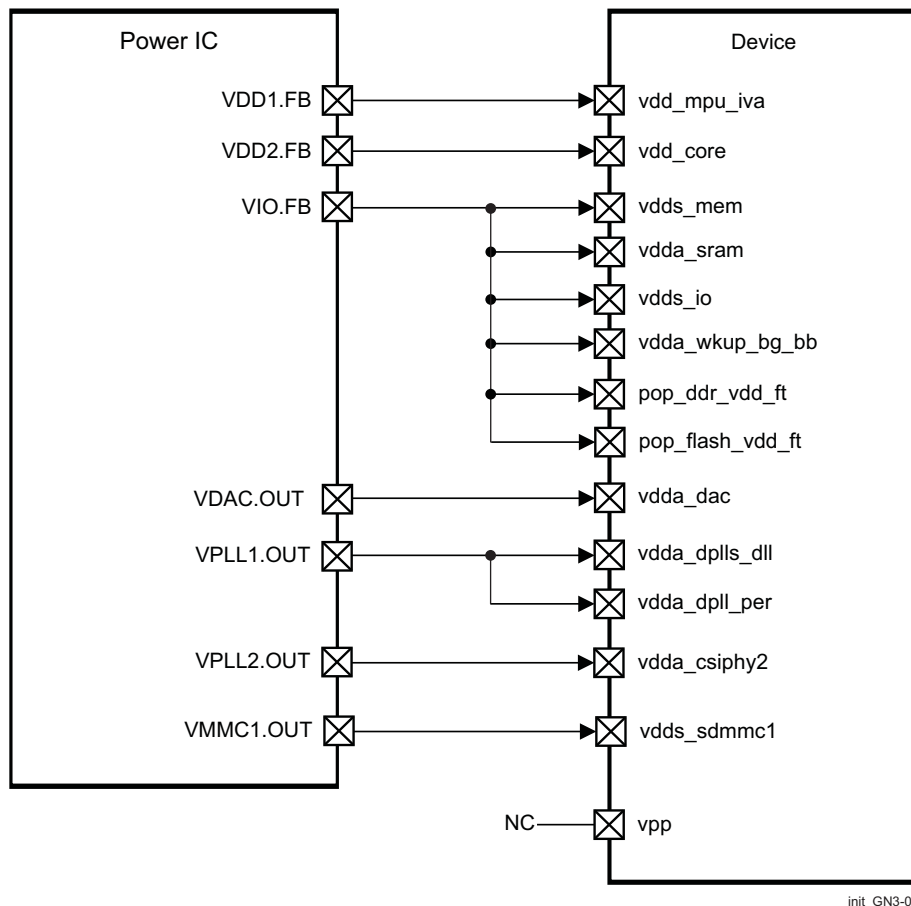

To accomplish a successful boot-up operation with a general-purpose (GP) device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the microprocessor unit (MPU), must be connected and driven correctly for successful device initialization. The following sections describe the specific requirements for the preinitialization stage.

26.2.1 Power Connections

The device can be supplied by an external power integrated circuit (IC).

Figure 26-2 shows example power connections between the device and the power IC.

Figure 26-2. Device and Power Connections

init_GN3-001

NOTE: Figure 26-2 is an example of power connections between the device and the power IC. These connections depend on the application: For example, if a serial display or camera interface is used, it must be supplied by a low-dropout (LDO) regulator (low noise).

NOTE:

- The sys_clkout output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset (POR), the hardware configuration enables the internal oscillator (assuming that the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

Table 26-1 describes the power pins.

Table 26-1. Power Pins⁽¹⁾

Device Voltage Pin Name	Description
vdd_mpu_iva	MPU and image and video accelerator (IVA) subsystem power supply
vdd_core	Core power supply
vdds_io	I/O power supply
vdds_mem	Memory, SDRC, and GPMC I/O power supply
vdda_wkup_bg_bb	Input power for wakeup, band gap and body bias low-dropout regulators (LDO)
vdda_sram	Input power for SRAM LDOs (common)
vdda_dppll_dll	Input power for digital phase-locked loops (DPLL) and delay-locked loop (DLL)
vdda_dppll_per	Input power for DPLL (peripheral)
vdda_csiphy1	Dedicated power supply for camera serial interface2 - CSI2a complex I/O
vdds_csiphy2	Dedicated power supply for CSI2b complex I/O
vdda_dsi	Dedicated power supply for display serial interface (DSI) complex I/O
vdda_dac	Video buffers and digital-to-analog converter (DAC) power supply
vdds_sdmmc1	Power supply for multimedia card (MMC)/secure digital (SD) dual voltage buffers
vpp	eFuse programming voltage
pop_ddr_vdd_ft	POP DDR core supply ⁽¹⁾
pop_flash_vdd_ft	POP FLASH core supply ⁽¹⁾
pop_flash_vpp_ft	POP FLASH vpp supply ⁽¹⁾

⁽¹⁾ The package-on-package (POP) device provides feedthroughs from the bottom of the package to the POP interface. Among these feedthroughs (FEEDTHROUGH balls), several provide power to the top memory device. The correct power supply to the feedthroughs must be provided based on memory requirements.

For more information about power management, see [Chapter 3, Power, Reset, and Clock Management](#).

26.2.2 Clock and Reset

26.2.2.1 Clock and Reset Overview

Figure 26-3 shows the clock and reset environment that gathers the clocks and reset signals related at the system level, as well as system expansion signals.

Figure 26-3. Clock and Reset Environment

The main features of the system interface are:

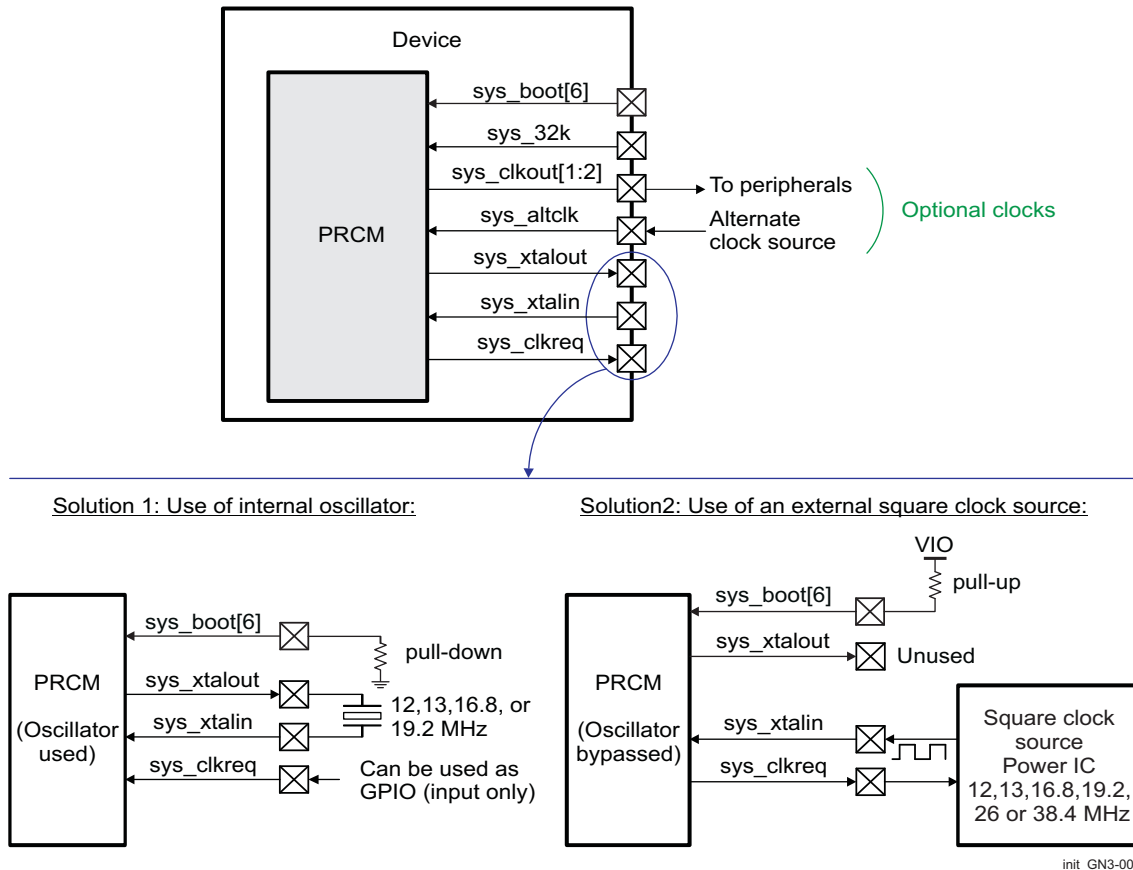

- A clock request output to an external square clock source
- 12, 13, 16.8, 19.2, 26, or 38.4-MHz reference clock input from the external crystal oscillator (only 12, 13, 16.8, or 19.2 MHz) or the digital clock input (all frequencies)
- 32-kHz CMOS clock input
- An additional clock input up to 54 MHz
- Two configurable output clocks
- Seven input signals to define the boot mode
- Two reset sources
 - POR (cold reset)
 - Bidirectional warm reset

26.2.2.2 Clock Configuration

26.2.2.2.1 Required System Input Clocks

Figure 26-4 shows the clock interface.

Figure 26-4. Clock Interface

NOTE:

- The sys_clkout output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After POR, the hardware configuration enables the internal oscillator (assuming that the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

The device operation requires two external input clocks, as follows:

- sys_32k: The 32-kHz frequency is used for low-frequency operation.
- sys_xtal (in/out): The system clock is the main clock source of the device. The system clock input can be connected in either of two ways:
 - Crystal quartz through the sys_xtalin and sys_xtalout pins, using an internal oscillator up to 19.2 MHz
 - Complementary metal oxide semiconductor (CMOS) digital clock (square wave) through the sys_xtalin pin. The oscillator is bypassed.

Table 26-2 lists the mapping for input sources.

Table 26-2. Mapping For Input Sources

Input Source	Mapping	Frequencies	Comment
Crystal quartz	sys_xtalin and sys_xtalout	12, 13, 16.8, or 19.2 MHz	Requires use of internal oscillator
Square clock (1.8 CMOS signal)	sys_xtalin (sys_xtalout unconnected)	12, 13, 16.8, 19.2, 26, or 38.4 MHz	Internal oscillator is bypassed.

Because sys_32k, sys_xtalin, and sys_xtalout have permanently assigned pin locations with no pad configuration for these pins through a system control module (SCM) register, only one source input at a time can be used.

26.2.2.2 Optional System Input Clock: *sys_altclk*

An additional clock can be provided through the *sys_altclk* input pin to supply internal peripherals, PLLs, a precise clock for National Television System Committee (NTSC) standard (54 MHz), and a universal serial bus (USB) full-speed (FS) controller (48 MHz). If not used as a clock input, this pin can be configured as a general-purpose input/output (GPIO), using the SCM CONTROL.CONTROL_PADCONF_I2C3_SDA register. As an example, to use the *sys_altclk* pin, the CONTROL.CONTROL_PADCONF_I2C3_SDA[18:16] MUXMODE1 bit field must be set to 0x01.

26.2.2.3 Optional System Output Clock: *sys_clkout1* and *sys_clkout2*

Two output clocks (*sys_clkout1* and *sys_clkout2* pins) are available:

- *sys_clkout1* can output the oscillator clock. Its OFF state polarity is programmable.
- *sys_clkout2* can output the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz), the core clock (CORE DPLL output), 96 MHz, or 54 MHz. *sys_clkout2* can be divided by 2, 4, 8, or 16, and its OFF state polarity is programmable.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production.

The clocks can be managed by software with the appropriate register in the power, reset, clock, management (PRCM) module:

- *sys_clkout1* is managed using PRCM.PRM_CLKOUT_CTRL and PRCM.PRM_POLCTRL[2].
- *sys_clkout2* is managed using PRCM.CM_CLKOUT_CTRL and PRCM.CM_CLKSEL1_PLL[28:27].

26.2.2.3 Reset Configuration

The *sys_nrespwron* reset pin resets the entire chip during POR.

The *sys_nreswarm* reset pin resets the entire chip when the device is supplied and operating, except for the following:

- Part of synchronous dynamic RAM (SDRAM) controller (SDRC)
- Part of IVA
- Part of PRCM
- Control module
- Watchdog
- 32-kHz synchronization timer
- DPLLs
- SmartReflex™ modules

CAUTION

sys_nrespwrn must be driven low during a power-up sequence.

sys_nreswarm is a bidirectional reset. When an internal reset occurs, sys_nreswarm goes low and resets all the peripherals. The sys_nreswarm output is open-drain; consequently, an external pullup resistor is required.

sys_nrespwrn and sys_nreswarm have permanently assigned pin locations.

At reset, the cause of reset is stored in the PRCM.RM_RSTST_MPU register and used by the boot ROM code.

26.2.3 Boot Configuration

Six external pins (sys_boot[5:0]) are used to select interfaces or devices for booting. The sys_boot[6] pin is used to select whether the internal oscillator is bypassed.

These seven pins are sampled and latched onto the CONTROL.CONTROL_STATUS register after POR. After booting, these pins can be used for other functions and the associated CONTROL.CONTROL_STATUS bits are not updated by the new functionality. For more information about pad multiplexing configuration, see [Chapter 13, System Control Module](#).

NOTE: If used as GPIOs, these pins must be used in output mode. To ensure that the sys_boot[6:0] input values are selected by the pullup/down on sys_boot[6:0] pins at POR, these GPIOs must be used only in output mode. Because these balls have no pullup/down capacity, care must be taken when choosing to use these GPIOs.

[Table 26-3](#), [Table 26-4](#), and [Table 26-5](#) are decoding tables for sys_boot pins. Depending on sys_boot pin configuration during the reset (leftmost column), the ROM code tries to boot on the first booting device listed. If the boot fails on this first booting device, the ROM code tries the second booting device, then the third, then the fourth.

The following names are used in the tables:

- Memory types:
 - Execute in place (XIP): XIP memory without wait monitoring enabled (NOR flash memories)
 - XIP wait: XIP memory with wait monitoring
 - DOC: DiskOnChip™ memory (H3 device types)
 - NAND: NAND flash memories (non-XIP)
 - OneNAND: OneNAND™ and Flex-OneNAND™ flash memories
 - MMC1: MMC or SD/ eMMC or eSD flash cards connected to the first MMC/Secure Digital Input/Output (SDIO1) card interface
 - MMC2: MMC or SD/ eMMC or eSD flash cards to the second (MMC/SD/SDIO2) card interface
 - MMC2_H (Hybrid): MMC or SD/ eMMC or eSD flash cards connected to the second (MMC/SD/SDIO2) card interface, but the memory core is powered by VMMC1_LDO of the power-management IC.
- Peripheral interfaces:
 - USB: High-speed (HS) USB
 - UART3: UART interface
- Permanent booting devices are in *italics*.

[Table 26-3](#) and [Table 26-4](#) list the sys_boot pin configuration after a POR.

NOTE: After reset release, the ROM code tries to boot from several interfaces, one after the other until it finds a bootable one. These interfaces (GPMC, MMC1, MMC2, USB, and UART) are selected in a specific order defined by the `sys_boot` settings.

As a consequence, if the first bootable interface found by the ROM code is not the first one in the list, some activity occurs on the interfaces tested before the bootable one.

This must be considered in case these intermediary interfaces are connected to other peripherals for other purposes (for example, an LED connected to a GPMC pad muxed internally to a GPIO).

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pins that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- HS USB boot: If the internal USB transceiver of a supported power-management IC is used, the IC's configuration interface must be connected to the device through I2C1. No other I²C interface is supported for this purpose. If other USB transceiver is used, the ROM code assumes it is powered, clocked, and out of reset.

26.3 Power, Clocks, and Reset Power-Up Sequence

See [Chapter 3, Power, Reset, and Clock Management](#), section *Power-Up Sequence*, for the power-on sequence, including power supplies, clocks, and reset signals.

26.4 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

26.4.1 Booting Overview

CAUTION

To use the level 2 (L2) cache with the device, the ROM code provides three primitive services. These services are implemented in monitor mode and do not use any resources outside the MPU subsystem. The services are described below. To call a service, a register r12 must be set to service ID and the SMI instruction must be executed.

- r12=1: To use the L2 cache, all L2 line data must be invalidated through the CP15 registers. This service invalidates the entire L2 cache and must be performed after a POR or a loss of L2 cache after reset. This register can also be read.
- r12=2: This service writes the value of the central processing unit (CPU) register R0 in the L2 cache auxiliary control register. This register can also be read.
- r12=3: This service writes the value of the CPU register R0 in the auxiliary control. This register can also be read. For more information about ARM L2 cache and registers, see the *Cortex-A8 Technical Reference Manual*. For more information about ARM CP15 registers, see the *ARM Architecture Reference Manual*.

NOTE: When the ROM Code branches to the first instruction of a GP device Initial software, the L2 cache is disabled.

26.4.1.1 Booting Types

Bootting is the process of starting a bootstrap from one of the booting memories.

The ROM code has two booting functions: peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burned, a software reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (HS USB or UART 3) by using the sys_boot pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

NOTE: After reset release, the ROM code tries to boot from several interfaces, one after the other until it finds a bootable one. These interfaces (GPMC, MMC1, MMC2, USB, and UART) are selected in a specific order defined by the `sys_boot` settings.

As a consequence, if the first bootable interface found by the ROM code is not the first one in the list, some activity occurs on the interfaces tested before the bootable interface. This should be considered in case these intermediary interfaces are connected to other peripherals for some other purposes (an LED connected to a GPMC pad muxed internally to a GPIO for instance).

Table 26-6 lists the pin multiplexing according to boot peripheral.

Table 26-6. Pin Multiplexing According to Boot Peripheral

Boot Device	Pins
NAND/OneNAND	General-purpose memory controller (GPMC) pins in mode 0
XIP memory	GPMC pins in mode 0
DiskOnChip	GPMC pins in mode 0
MMC/SD1	MMC1 pins in mode 0
MMC/SD2	MMC2 pins in mode 0
UART3	UART3 pins in mode 0
HS USB	HSUSB0 pins in mode 0

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pins that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.
- HS USB boot: If the internal USB transceiver of a supported power-management IC is used, the IC's configuration interface must be connected to the device through I2C1. No other I²C interface is supported for this purpose. If other USB transceiver is used, the ROM code assumes it is powered, clocked, and out of reset.

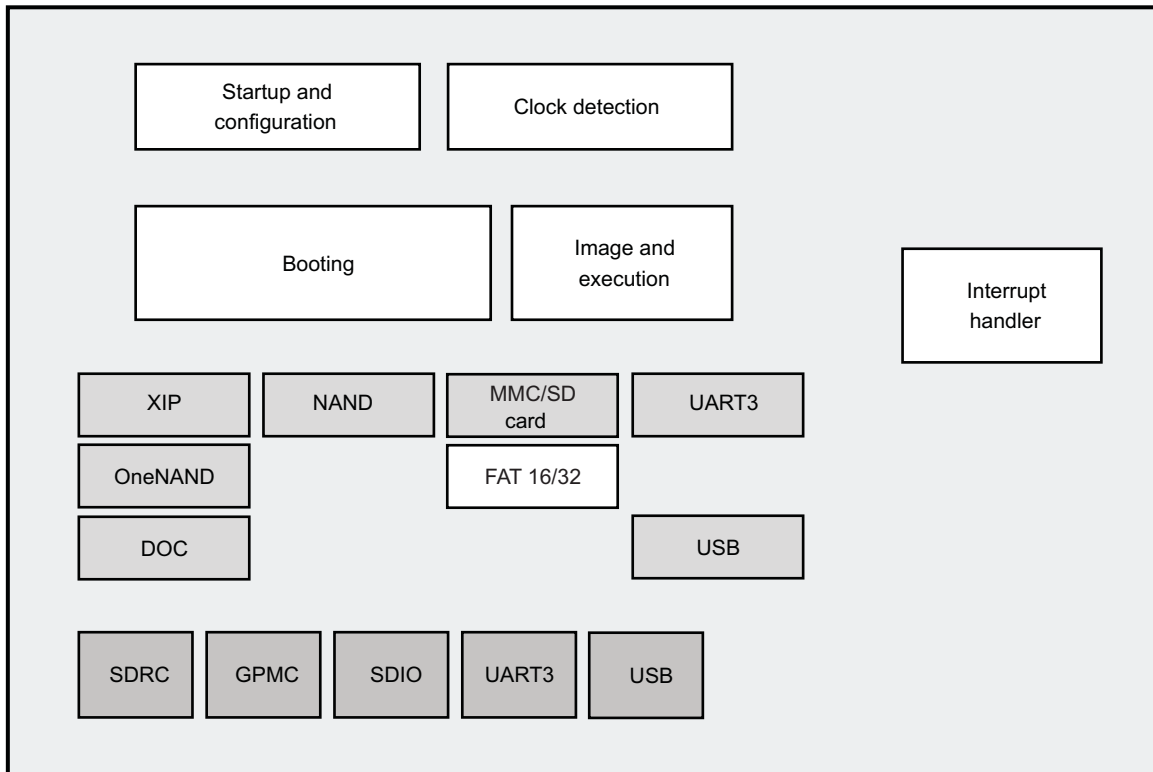

26.4.1.2 Main Features

The ROM code architecture is shown in [Figure 26-5](#). The ROM code is made up of several modules:

- The start-up module takes care of basic system configuration and dispatches control to the booting module.
- The clock detection module supports startup by detecting the system clock frequency.
- The booting module uses several device drivers to boot from an external device.
- The device drivers implement device protocols and perform logical operation on a device. They are abstracted from interface hardware by several interface drivers, which are responsible for interacting with hardware interface facilities.
- The interrupt handler module provides services used by all modules. It allows registering interrupt service routines (ISRs) and calls them when an interrupt occurs.

[Figure 26-5](#) shows each module.

Figure 26-5. ROM Code Architecture

- Device drivers
- Interface drivers
- Other modules

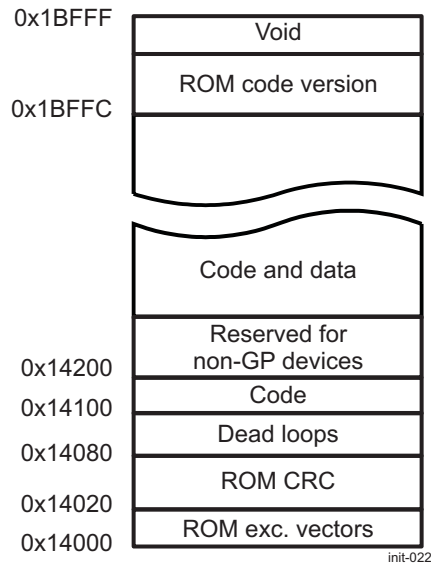

init-006

26.4.2 Memory Map

26.4.2.1 ROM Memory Map

Figure 26-6 shows the ROM memory map.

Figure 26-6. 32KB ROM Memory Map

- ROM exception vectors
Exceptions are redirected to ROM exception vectors (see [Table 26-7](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses in the PC register.

Table 26-7. ROM Exception Vectors

Address	Exception	Content
14000h	Reset	Branch to the public ROM code startup
14004h	Undefined	PC = 4020FFC8h
14008h	Software interrupt (SWI)	PC = 4020FFCCh
1400Ch	Prefetch abort	PC = 4020FFD0h
14010h	Data abort	PC = 4020FFD4h
14014h	Unused	PC = 4020FFD8h
14018h	IRQ	PC = 4020FFDCh
1401Ch	FIQ	PC = 4020FFE0h

- ROM code cyclic redundancy check (CRC)
The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 14000h – 1BFFFh. The 4-byte CRC code is stored at location 14020h.
- Dead loops
Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see [Table 26-8](#)).

Table 26-8. Dead Loops

Address	Purpose
14080h	Undefined exception default handler
14084h	SWI exception default handler
14088h	Prefetch abort exception default handler
1408Ch	Data abort exception default handler
14090h	Unused exception default handler
14094h	IRQ exception default handler
14098h	FIQ exception default handler
1409Ch	Validation tests Pass
140A0h	Validation tests Fail
140A4h	Bootling failed: No more bootling devices
140A8h	Image not executed or returned
140ACh	Reserved
140B0h	Reserved
140B4h	Reserved
140B8h	Reserved
140BCh	Reserved

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 140C0h. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code

This space is used to keep code.

- Code and data

This space is used to keep code and other data.

- ROM code version

The ROM code version consists of two decimal numbers: major and minor. The major number is 18. The minor number identifies the ROM code version. The minor number is not aligned with the ROM code release number, but it can identify it. The ROM code version is coded as hexadecimal readable values (for example, ROM version 18.04 is coded as a 32-bit word: 00001804h).

26.4.2.2 RAM Memory Map

Figure 26-7 shows the RAM memory map. The partitioning of the on-chip SRAM shown in Figure 26-7 is used only during the booting process.

Figure 26-7. 64KB RAM Memory Map of GP Devices

- **Downloaded image**
This space is used by the public ROM code to store a downloaded booting image.
- **Public stack**
This space is reserved for stacks.
- **Tracing data**
The public ROM code tracing data is described in [Table 26-9](#). More information about ROM code tracing can be found in [Section 26.4.9, Tracing](#).

Table 26-9. Tracing Data

Address	Size [Bytes]	Description
0x4020FFB0	4	Current tracing vector, word 1
0x4020FFB4	4	Current tracing vector, word 2
0x4020FFB8	4	Current copy of the PRM_RSTST register (reset reasons)
0x4020FFBC	4	Cold reset run tracing vector, word 1
0x4020FFC0	4	Cold reset run tracing vector, word 2
0x4020FFC4	4	Reserved

- **RAM exception vectors**
The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 26-10](#) shows the contents of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions that load into the PC the value in the next seven addresses. These instructions are executed when an exception occurs, because they are called from ROM exception vectors. By default, all exceptions are redirected to the exception dead loops. Users can redirect an exception to another handler by writing its address to the appropriate position from 0x4020FFE4 to 0x4020FFFC, or by overriding instructions between addresses from 0x4020FFC8 to 0x4020FFE0.

Table 26-10. RAM Exception Vectors

Address	Exception	Content
0x4020FFC8	Undefined	PC = [0x4020FFE4]
0x4020FFCC	SWI	PC = [0x4020FFE8]
0x4020FFD0	Prefetch abort	PC = [0x4020FFEC]

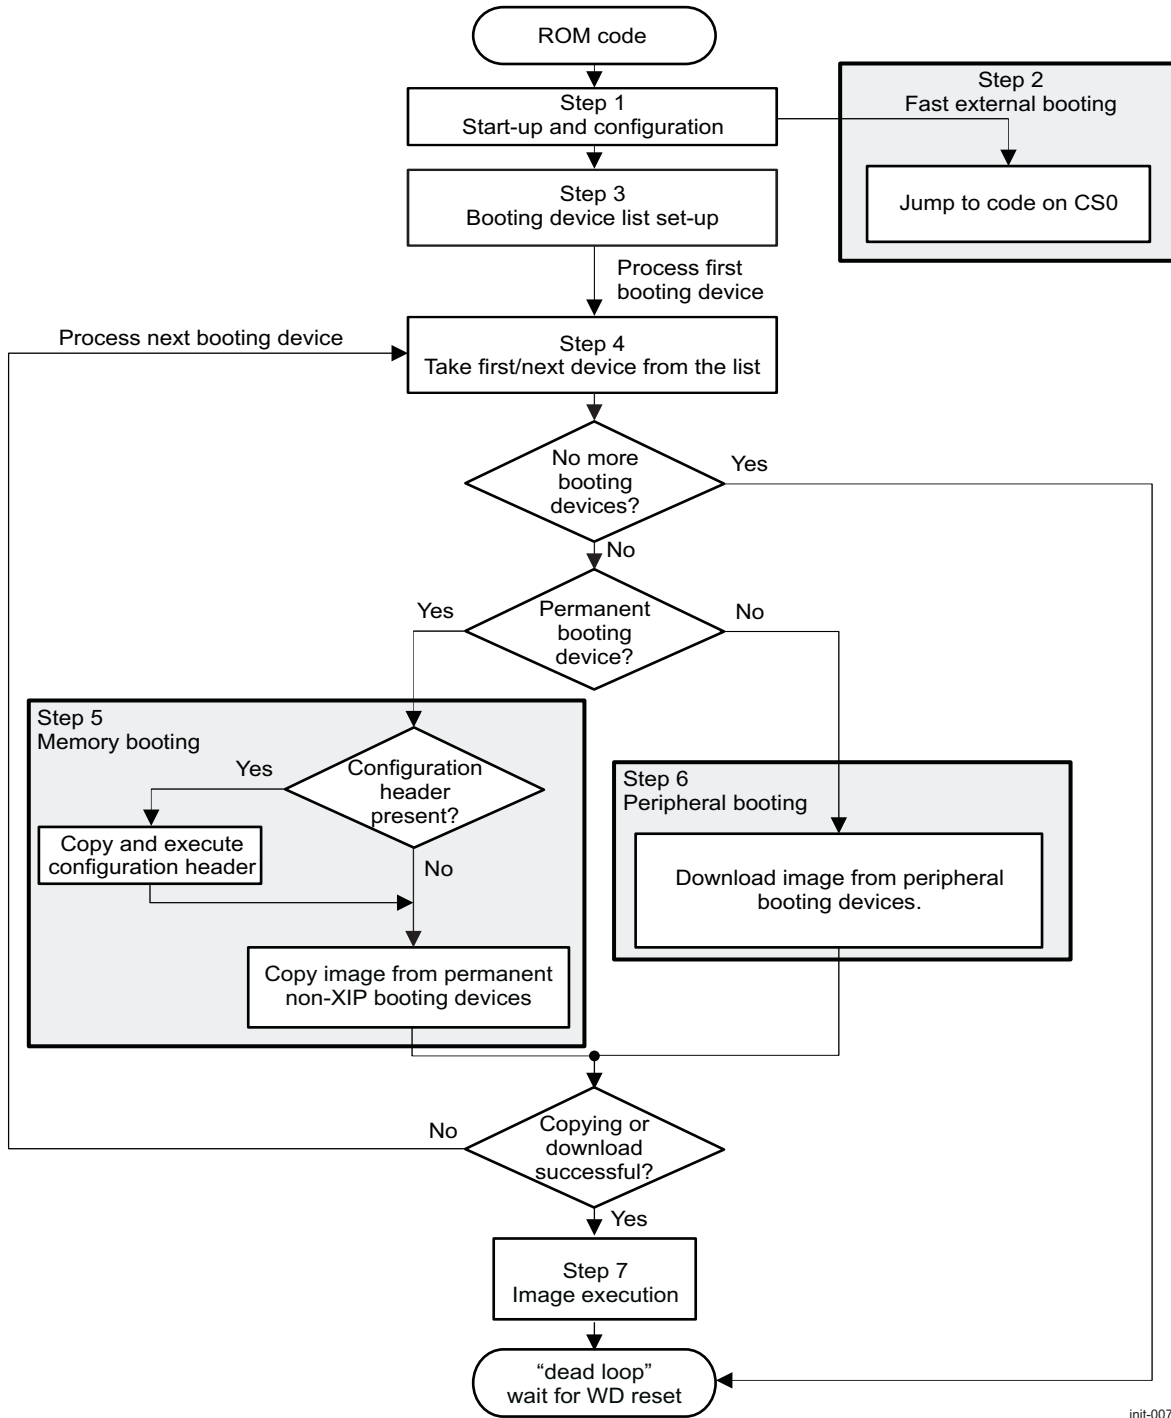

Table 26-10. RAM Exception Vectors (continued)

Address	Exception	Content
0x4020FFD4	Data abort	PC = [0x4020FFF0]
0x4020FFD8	Unused	PC = [0x4020FFF4]
0x4020FFDC	IRQ	PC = [0x4020FFF8]
0x4020FFE0	FIQ	PC = [0x4020FFFC]
0x4020FFE4	Undefined	0x14080
0x4020FFE8	SWI	0x14084
0x4020FFEC	Prefetch abort	0x14088
0x4020FFF0	Data abort	0x1408C
0x4020FFF4	Unused	0x14090
0x4020FFF8	Interrupt request (IRQ)	0x14094
0x4020FFFC	Fast interrupt request (FIQ)	0x14098

26.4.3 Overall Booting Sequence

Figure 26-8 is the ROM code flow chart.

Figure 26-8. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

- Step 1. Basic configurations and initializations.
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to the external addressable memory as soon as possible.
- Step 3. A booting device list is created (see [Section 26.4.4.3, Booting Device List Setup](#)). The list consists of all booting devices to be searched for a booting image. The list is created based on the sys_boot pins and the software booting configuration described in [Section 26.4.4.4, Software Booting Configuration](#). The software booting configuration structure is in the scratchpad memory and can be written by software before executing a software reset. The scratchpad memory is an internal RAM memory that keeps its contents as long as the power is supplied and is not influenced by wakeups or resets. After a software reset, the software booting configuration has priority over the sys_boot pin configuration.
- Step 4. After the booting device list is set, the booting procedure examines the booting devices on the list serially and executes memory booting or peripheral booting, depending on current booting device type:
 - Memory booting is executed when the booting device is permanent: XIP memory, NAND, DiskOnChip, OneNAND/Flex-OneNAND, or MMC/SD cards.
 - Peripheral booting is executed when booting device is temporary: UART or USB.
- Step 5. Memory booting reads data from memory type booting devices. Memory booting is described in detail in [Section 26.4.7, Memory Booting](#).
- Step 6. Peripheral booting downloads data from communication interfaces. The ROM code uses a simple logical protocol with peripheral booting. First, the device sends an ASIC-ID structure to inform the host about the peripheral booting start. The host responds by sending a booting message that can have one of three meanings:
 - Skip peripheral booting.
 - Continue peripheral booting.
 - Change the booting device.

If the message is to continue, the host sends the entire image preceded by its size. Peripheral booting is described in [Section 26.4.5, Peripheral Booting](#).

Step 7. For this booting device, the image is automatically started.

An additional feature of the booting module is the execution of the configuration header (CH). The CH configures the system for faster and more flexible booting from the selected permanent booting device. The CH, which is optional, is described in [Section 26.4.8.2, Configuration Header](#).

26.4.4 Startup and Configuration

26.4.4.1 Startup

The ROM code starts at address 0x0001 4000.

26.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 13 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL, set to provide 96 MHz and 48 MHz for peripheral blocks
- MPU DPLL, set to provide 96 MHz for the Cortex-A8 MPU
- Core DPLL, set to provide 192, 96, 48, or 24 MHz for various blocks, such as interconnect, clocked by this DPLL output

The multipliers and dividers of the DPLLs are set to values which depend on the input clock detected.

[Table 26-11](#) summarizes the ROM code default settings for key clocks.

Table 26-11. ROM Code Default Clock Settings

Clock	Frequency [MHz]	Source
CORE.CLK	192	CORE DPLL output
L3x2.CLK	192	CORE.CLK
L3.ICLK	96	CORE.CLK/2
L4.ICLK	48	L3.ICLK/2
RM clock	24	L4.ICLK/2
MPU	96	CORE.CLK/2 (MPU DPLL in bypass)

The DPLLs and other settings are configured by default after each type of reset to give the ROM code the same working conditions. However, it is possible to override the default clock settings by means of the software booting configuration; for details, see [Section 26.4.4.4, Software Booting Configuration](#).

There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in this paragraph
- Software booting configuration after a software reset, described in [Section 26.4.4.4, Software Booting Configuration](#)
- CH, described in [Section 26.4.8.2, Configuration Header](#). This configuration can be blocked by the software booting configuration; this is possible during the memory booting. The CH lets the user have a known configuration (about GPMC, SDRC, and clock registers) after memory booting.

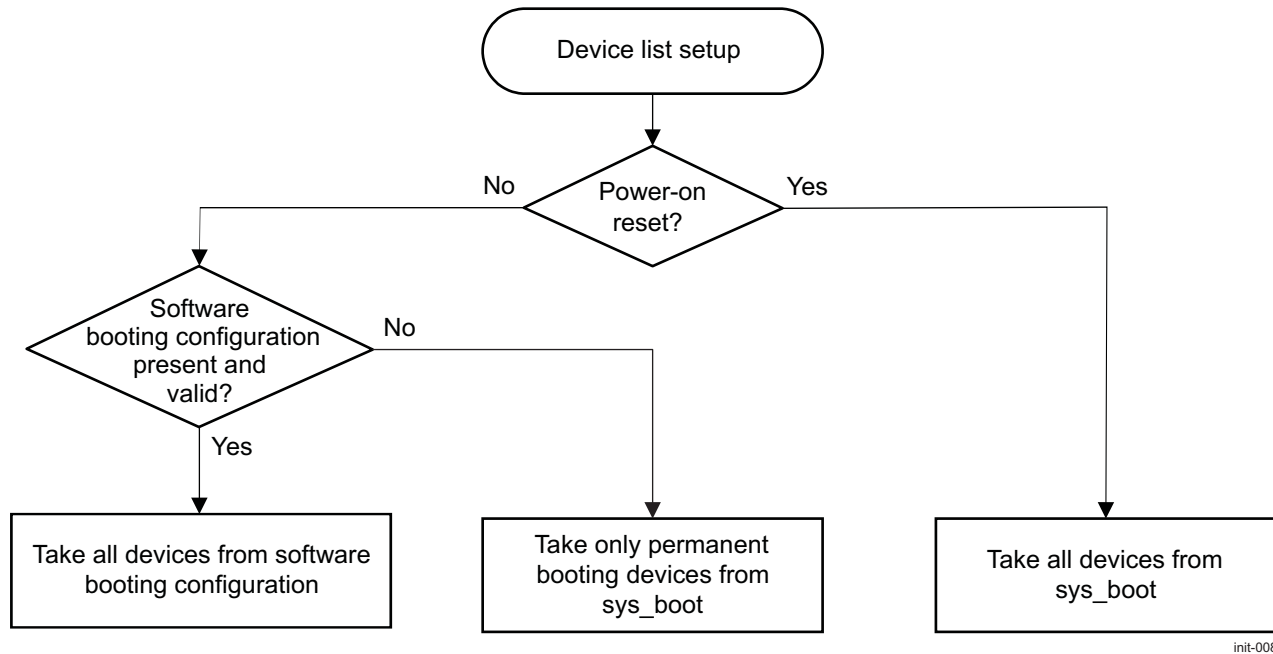

26.4.4.3 Booting Device List Setup

The ROM code creates a booting device list based on two sources:

- The software booting configuration is stored in the scratchpad memory.
- The sys_boot[5:0] pins are used to index the booting device table from which the list of booting devices is extracted.

[Figure 26-9](#) shows how the ROM code sets up the booting device list depending on the reset source.

NOTE: Only permanent booting devices are put on the list when reset is not power on and booting devices are taken from the sys_boot pins. Users can force peripheral booting after software reset using software booting configuration.

Figure 26-9. Booting Device List Setup

26.4.4.4 Software Booting Configuration

The software booting configuration is stored in the special scratchpad memory, which is not cleared after resets or wakeups. The software booting configuration is a simple structure at the address stored at the first location of available scratchpad memory: 0x48002910. [Table 26-12](#) shows the software booting configuration. There are two sections in this structure:

- The first section provides booting devices for the booting device list.
- The second section provides clock settings, which are applied before booting.

The sections are not mandatory and their order is not important. The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration overwrites the CH settings.

Table 26-12. Software Booting Configuration Structure

Field	Size [bytes]	Description
Booting Configuration		
Section 1 key	4	Synchronization key for section 1: 0xCF00AA01
Section 1 size	4	Size of section 1: 0x0000000C (12)
Flags	2	Bits [4:1]: Mask the CH, when one of these 4 bits is set to 1, the CH section is not analyzed: [1]: SETTINGS section [2]: RAM [3]: FLASH (GPMC) [4]: MMCSD

26.4.5 Peripheral Booting

26.4.5.1 Overview

The ROM code can boot from two different peripherals:

- HS USB: HS USB interface
- UART 3: Baud rate 115.2 Kbps, 8 bits, even parity, 1 stop-bit

The purpose of booting from a peripheral is to boot from an external host, such as a PC. This booting method is used primarily for programming flash memories connected to the device. The protocol is common to all peripherals. Some minor exceptions are described in the following sections. The common peripheral booting protocol is shown in [Figure 26-10](#).

Figure 26-10. Common Peripheral Booting Protocol

The ROM code first initializes the interface and sends a message called ASIC-ID to a host. The content of this message is summarized in [Table 26-13](#). The host uses this message to send only appropriate data to the device according to the identification codes sent.

The ROM code waits 300 ms for an answer from UART and 3 s from USB host. If a time-out occurs, the peripheral booting returns to the main booting procedure with TIMEOUT status.

Table 26-13. ASIC-ID Structure

ASIC-ID Item	Size [Bytes]	Description
Items	1	Number of subblocks
ID subblock	7	Device identification information
Reserved for non-GP devices	4	Reserved
ID subblock	23	Identification data
Reserved for non-GP devices	23	Reserved
Checksum subblock	11	CRC (4 bytes)

The host can send different messages, as described in [Table 26-14](#). If the second or third message is not received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which determines the next booting device according to the boot message received.

If the first message is received without a time-out, the image size (a 32-bit word) and the image itself are expected to be received. The image is downloaded directly at address 0x40200000 in the internal RAM.

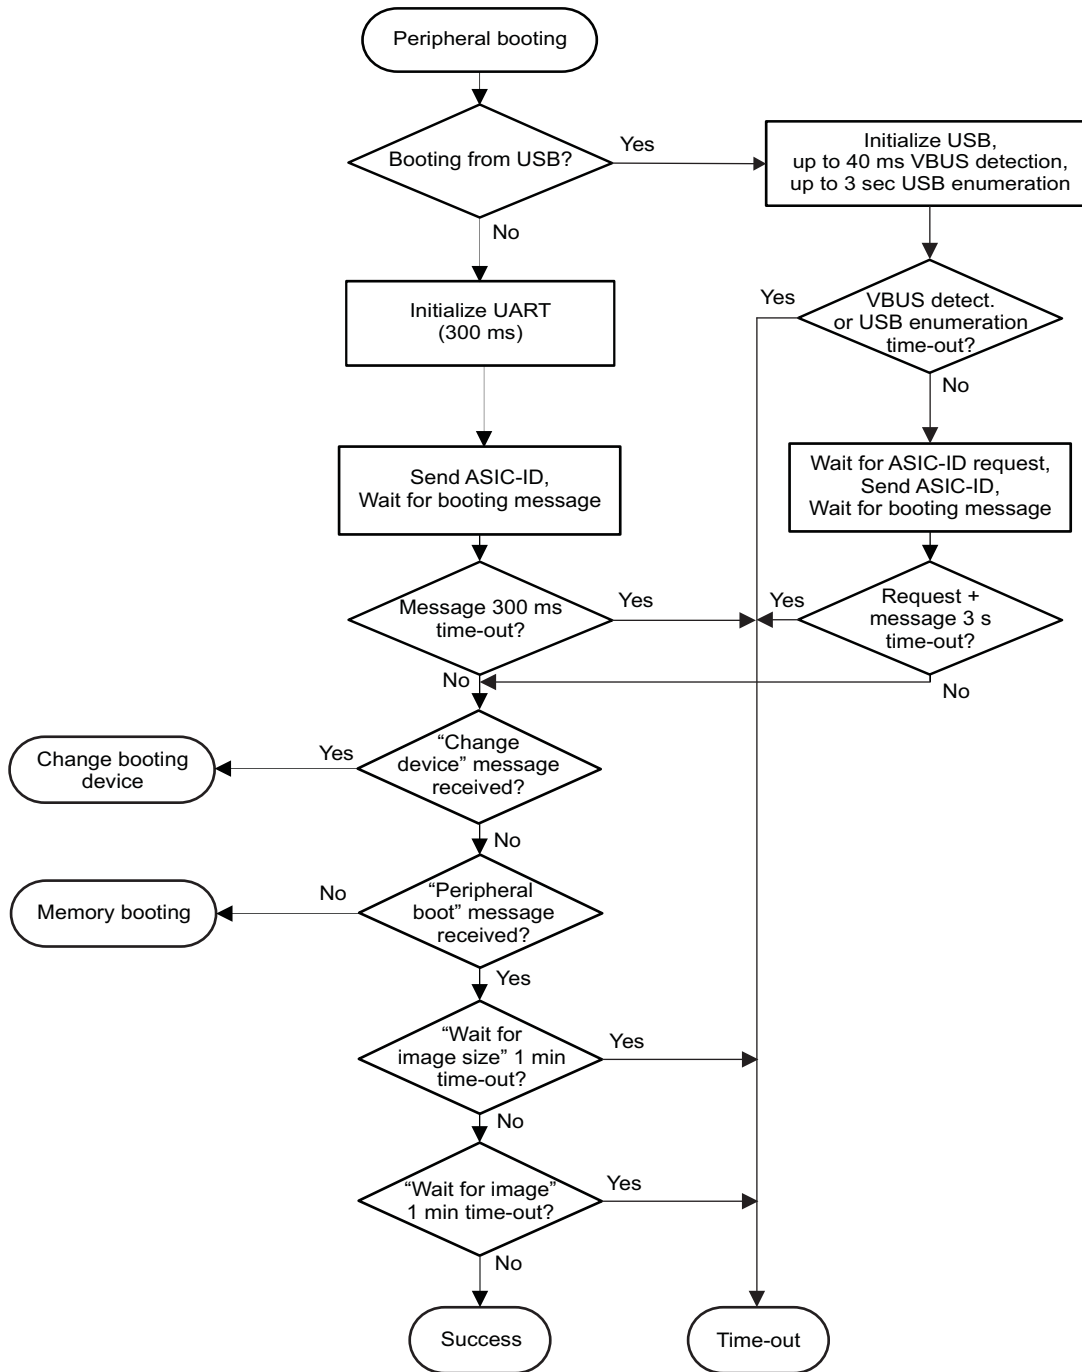

The ROM code waits up to 1 minute for completion. If the downloading procedure does not complete before this period, the peripheral booting fails. If the download passes, the peripheral booting succeeds and the image can be executed.

Table 26-14. Boot Messages

Message Name	Value	Description
Peripheral boot	0xF0030002	Continue peripheral booting.
Change booting device	0xF003XX06	Skip current peripheral booting and continue booting from booting device type indicated by XX: 0x00: Void, no booting device 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x08: MMC/SD2 Hybrid connection 0x09..0x0F: Reserved 0x10: UART 0x11: HS USB Others: Reserved
Next booting device	0xFFFFFFFF	Skip current booting device and move to the next booting device on the device list.
Memory booting	Others	Skip current peripheral booting and move to the first booting device for memory booting.

Figure 26-11 shows the peripheral booting procedure.

Figure 26-11. Peripheral Booting Procedure

init-010

26.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3 at UART3 pins
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX with software flow control (XON/XOFF). The other UART pins are left at their default configuration.
- The UART wait for boot message time-out is 300 ms.

26.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HS USB interface
- USB 2.0 transceiver macrocell interface (UTMI)+ low pin interface (ULPI) 8-bit data transceiver support (single data rate)
- Power IC detection and automatic configuration of its USB transceiver using I2C1
- The enumeration time-out is 3 seconds.
- The USB wait for boot message time-out is 3 seconds

The ROM code USB driver conforms with the USB 2.0 specification and the USB on-the-go (OTG) supplement. It supports transactions at HS (that is, 480 Mbps) and FS (that is, 12 Mbps). During peripheral booting, only the USB device functionality is used. The driver resides in the on-chip memory (OCM) ROM, which is small. The driver therefore contains the minimum functionality needed as a USB device and is not a full-fledged driver. It does not contain the functionality needed for a USB host. The device functionality of the USB OTG controller is used for the peripheral booting process in the ROM code.

26.4.5.3.1 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable information that describes a descriptor. These descriptor details can be used for tool development or debugging:

- Device descriptor

A device descriptor contains general information about a USB device, including information that applies globally to the device and all device configurations. A USB device has only one device descriptor.

Because the ROM code uses the HS feature of the USB core, a device-qualifier descriptor is required. [Table 26-15](#) describes the device descriptors.

Table 26-15. Device Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x01	Device descriptor type
bcdUSB	0x0210	USB specification release number in binary coded decimal (BCD) format
bDeviceClass	Vendor-specific (0xFF)	Class code
bDeviceSubClass	Vendor-specific (0xFF)	Subclass code
bDeviceProtocol	Vendor-specific (0xFF)	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
idVendor	0x0451	Vendor ID (TI default table)
idProduct	Device-specific (0xD00E)	Product ID (TI default table)

Table 26-15. Device Descriptor (continued)

Field	Value	Description
bcdDevice	0x0000	Device release number
iManufacturer	See values in Section 26.4.5.3.2 .	Index of string descriptor describing manufacturer
iProduct	See values in Section 26.4.5.3.2 .	Index of string descriptor describing product
iSerialNumber	See values in Section 26.4.5.3.2 .	Index of string descriptor describing device serial number
bNumConfigurations	0x01	Number of possible configurations

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). [Table 26-16](#) describes a device-qualifier descriptor.

Table 26-16. Device-Qualifier Descriptor

Field	Value	Description
bLength	0x0a	Size of this descriptor in bytes
bDescriptorType	0x06	Device-qualifier descriptor type
bcdUSB	0x0210	USB specification release number in BCD
bDeviceClass	0xFF	Class code
bDeviceSubClass	0xFF	Subclass code
bDeviceProtocol	0xFF	Protocol code
bMaxPacketSize0	0x40	Maximum packet size for endpoint 0
bNumConfigurations	0x01	Number of possible configurations
bReserved	0x00	Reserved for future use

- Configuration descriptor

This descriptor gives information about a specific device configuration. The descriptor describes the number of interfaces supported by the configuration. See [Table 26-17](#) for details.

Table 26-17. Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x02	Configuration descriptor type
wTotalLength	-	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Other speed configuration descriptor

This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed. See [Table 26-18](#) for details.

Table 26-18. Other Speed Configuration Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x07	Other speed configuration descriptor type

Table 26-18. Other Speed Configuration Descriptor (continued)

Field	Value	Description
wTotalLength	-	Combined length of all descriptors
bNumInterfaces	0x01	Number of interfaces supported
bConfigurationValue	0x01	Value to use as an argument for the SetConfiguration() request
iConfiguration	Index	Index of string descriptor describing this configuration
bmAttributes	0xc0	Power setting and remote wakeup
bMaxPower	0x32	Maximum power consumption of the USB device

- Interface descriptor

This descriptor describes a specific interface in a configuration. See [Table 26-19](#) for details.

Table 26-19. Interface Descriptor

Field	Value	Description
bLength	0x09	Size of this descriptor in bytes
bDescriptorType	0x04	Interface descriptor type
bInterfaceNumber	0x00	Number of this descriptor
bAlternateSetting	0x00	Value to select the alternate setting
bNumEndpoints	0x02	Number of endpoints used for this interface
bInterfaceClass	0xFF	Class code
bInterfaceSubClass	0xFF	Subclass code
bInterfaceProtocol	0xFF	Protocol code
iInterface	Index	Index of string descriptor describing this interface

- Endpoint descriptor

Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. See [Table 26-20](#) and [Table 26-21](#) for details.

Table 26-20. BULK IN Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x81 (1 IN)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See ⁽¹⁾ .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 26-21. BULK OUT Endpoint Descriptor

Field	Value	Description
bLength	0x07	Size of this descriptor in bytes
bDescriptorType	0x05	Endpoint descriptor type
bEndpointAddress	0x01 (1 OUT)	Address of the endpoint on the USB device
bmAttributes	0x02 (Bulk)	Type of transfer
wMaxPacketSize	See ⁽¹⁾ .	Number of endpoints used for this interface
bInterval	0x00	Maximum NAK rate

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

See the tables describing string descriptors:

- The language ID string descriptor ([Table 26-22](#))
- The manufacturer ID string descriptor ([Table 26-23](#))
- The product ID string descriptor ([Table 26-24](#))
- The configuration string descriptor ([Table 26-25](#))
- The interface string descriptor ([Table 26-26](#))

Table 26-22. Language ID String Descriptor

Field	Value	Description
bLength	0x04	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
wLangId	0x0409 (US English)	Language ID code

Table 26-23. Manufacturer ID String Descriptor

Field	Value	Description
bLength	0x24	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	Texas Instruments	Manufacturer string

Table 26-24. Product ID String Descriptor

Field	Value	Description
bLength	0x12	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	Multimedia device or specific vendor string	Product string (Device specific)

Table 26-25. Configuration String Descriptor

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbc	Configuration string

Table 26-26. Interface String Descriptor

Field	Value	Description
bLength	0x08	Size of this descriptor in bytes
bDescriptorType	0x03	String descriptor type
bString	pbi	Interface string

26.4.5.3.2 USB Customized Descriptors

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. Table 26-27 lists the parameters that depend on VID value.

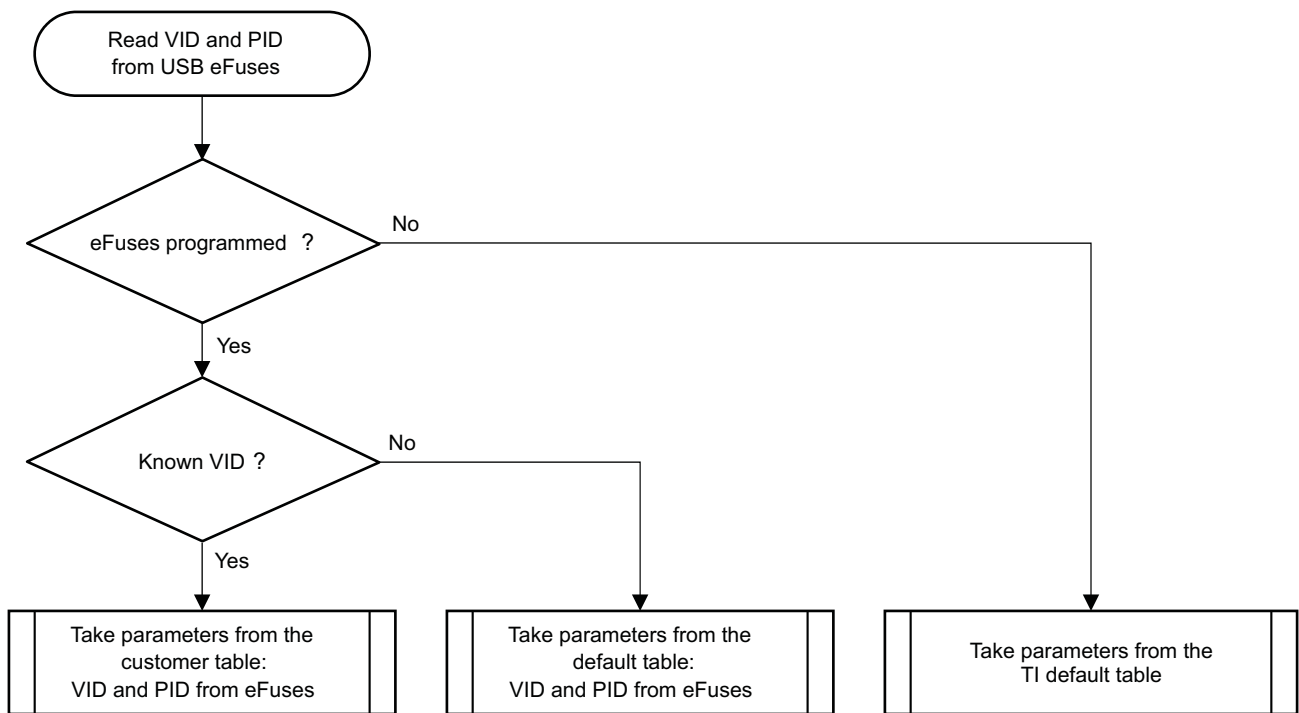

Table 26-27. Customized Descriptor Parameters

Parameter	Size [Bytes]	Default Values	TI Default Values
Device ID code	2	0x0000	0x0000
Device class	1	0xFF	0xFF
Device subclass	1	0xFF	0xFF
Device protocol	1	0xFF	0xFF
Manufacturer	String	N/A	Texas Instruments
Product	String	Multimedia device or specific vendor string	Multimedia device or specific vendor string
Serial number	String	See ⁽¹⁾	See ⁽¹⁾

⁽¹⁾ The Standard device descriptor indicates that the device has no serial number.

Figure 26-12 describes an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

Figure 26-12. Customer USB Descriptor Selection

init-011

26.4.5.3.3 USB Driver Functionality

- Transactions supported

The following transactions are supported:

- Control transactions: Used for standard device requests
- Bulk transactions: Used for data transfer in the image downloading stage. The ASIC-ID is sent on the Bulk IN endpoint and the image is transferred over the Bulk OUT endpoint from the host.

The USB first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are responded to with the corresponding descriptors.

- Standard device request restrictions

Because the USB driver is used only by the ROM code for peripheral booting, some standard device requests are not supported by the driver. [Table 26-28](#) lists the standard device requests supported by the driver.

Table 26-28. Standard Device Requests Supported

Request	Description	Support
CLEAR_FEATURE	Sets/clears a specific feature	Supported only for ENDPOINT_HALT feature
GET_CONFIGURATION	Returns the current device configuration value	Yes
GET_DESCRIPTOR	Returns the specified descriptor	Yes
GET_INTERFACE	Returns the selected alternate setting for the specified interface	Yes
GET_STATUS	Returns the status for the specified recipient	Yes
SET_ADDRESS	Sets the device address	Yes
SET_CONFIGURATION	Sets the device configuration	Yes
SET_DESCRIPTOR	Updates existing descriptors or adds new descriptors	No. Runtime updating of descriptors is not supported.
SET_FEATURE	Sets or enables a specific feature	Supported only for ENDPOINT_HALT feature
SET_INTERFACE	Selects an alternate setting in an interface	No. Runtime setting of alternate features is not supported.
SYNCH_FRAME	Sets and reports an endpoint synchronization frame	No, because isochronous transfers are not used

26.4.6 Fast External Booting

26.4.6.1 Overview

The fast external boot is a special memory booting mode. It is a blind jump to a code in an external XIP device connected to chip-select 0 (CS0). Fast external booting lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

26.4.6.2 External Booting

[Figure 26-13](#) shows the fast external boot procedure. The code is at the beginning and is written in assembly. The code does not use any RAM.

Figure 26-13. Fast External Boot Procedure

26.4.7 Memory Booting

26.4.7.1 Overview

The memory booting process starts an external code in memory type booting devices. Because the device always uses the memory type booting devices for booting, they are called permanent booting devices. The supported permanent booting devices are:

- All NOR devices up to 2 Gb (256M bytes)
- NAND devices from 64Mb
- OneNAND/Flex-OneNAND devices from 512Mb
- SD/MMC/eSD/eMMC flash cards with **active** primary partition of type FAT12/16/32 or with raw data
- DiskOnChip H3 devices

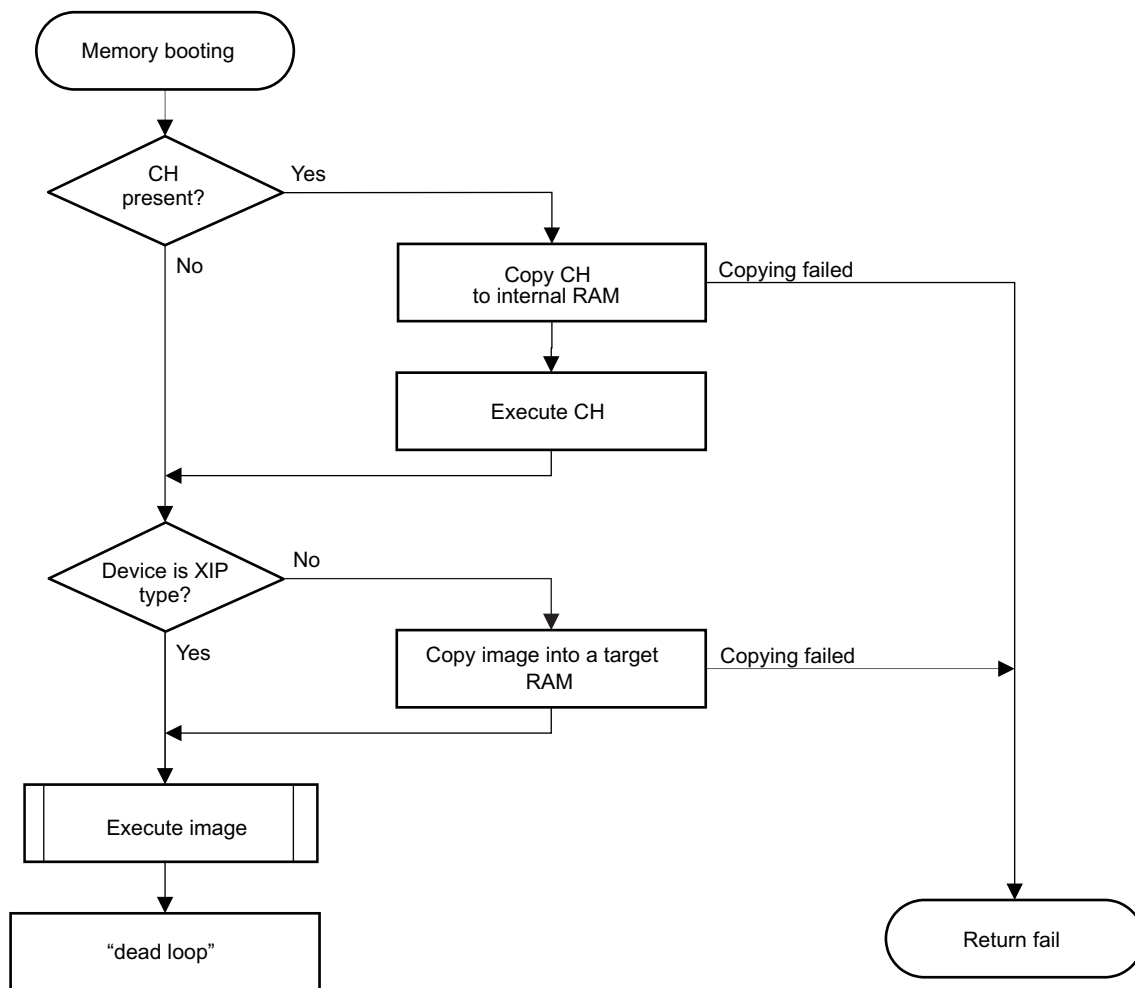

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying a code from a nondirectly addressable memory device (non-XIP) to RAM, where the code can be executed. Directly addressable memory devices are XIP devices.

Figure 26-14 is the general memory booting procedure common to all types of booting devices. First, the CH is copied to internal RAM. It is copied even for XIP booting devices, because the device can temporarily lose a connection with XIP memory during CH execution. The second step is to shadow the image, if the booting device is not XIP. The last step is image execution.

Unsuccessful execution or return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next booting device for booting.

Figure 26-14. Memory Booting Procedure

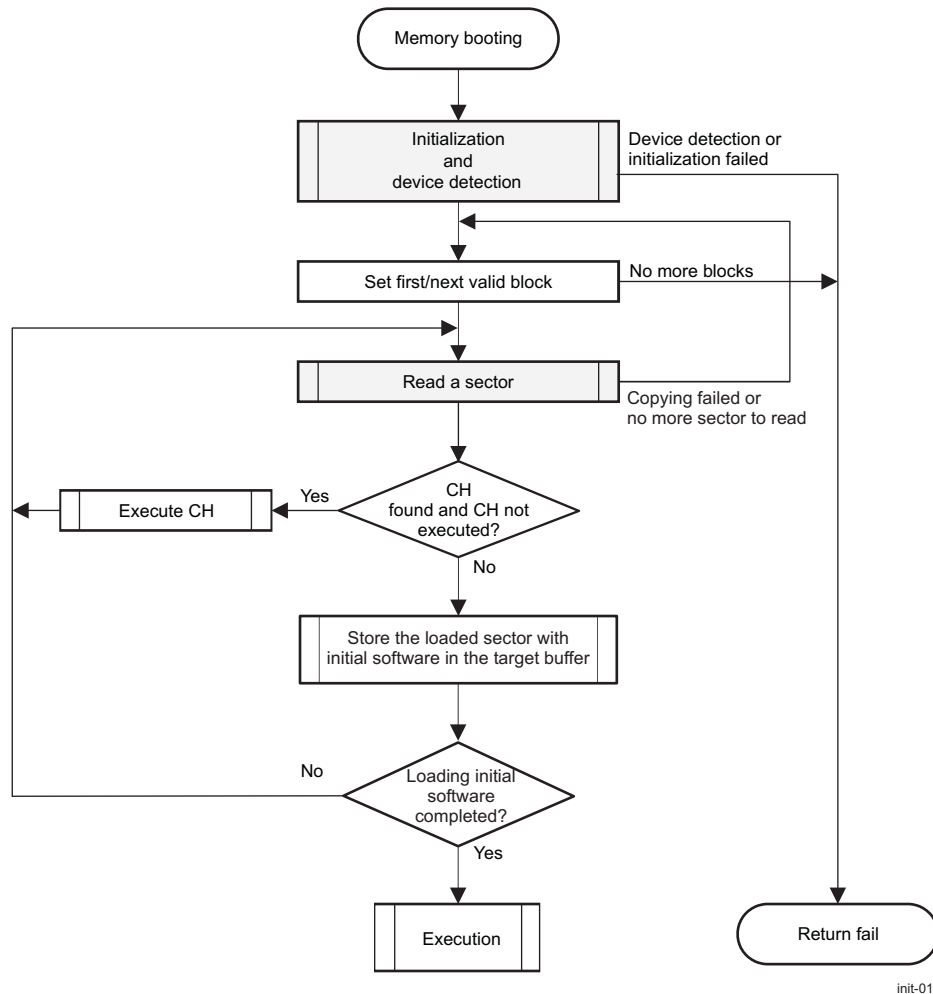

init-014

26.4.7.2 Non-XIP Memory

Figure 26-15 shows the procedure used when memory booting runs with non-XIP booting devices. The grayed procedures are specific to each booting device. NAND and OneNAND/Flex-OneNAND booting devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these booting devices. Other booting devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

Figure 26-15. Detailed Memory Booting for Non-XIP Booting Devices

init-015

Table 26-29 summarizes numbers of blocks and sectors that are searched during memory booting from devices requiring image shadowing. NANDs and OneNAND/Flex-OneNAND are organized with blocks, which are erasable units. DOC memory reserves only one block for booting, which overlaps the XIP part. MMC/SD+FAT card booting consists of reading a file. Because there is only one file read, it can be considered one block trial. When no file system is present the first sectors of two blocks (128KB each) are searched.

Table 26-29. Blocks and Sectors Searched on Non-XIP Memories

Memory	Maximum Number of Checked Blocks	Number of Sectors Searched
NAND	First 4	Number of sectors in a block ⁽¹⁾
OneNAND/Flex-OneNAND	First 4	8
DOC ⁽²⁾	1	4
MMC/SD + FAT system	1 file	
MMC/SD raw	2	1

⁽¹⁾ Depends on NAND type

⁽²⁾ Because XIP booting always precedes DOC booting and the same data is used for XIP areas, the DOC memory image must contain the first sector filled with 0xFF or 0x00. Therefore, a void sector at the beginning makes XIP booting fail and moves to DOC booting.

The following sections describe the supported booting device types.

For more information about the GPMC module, see [Chapter 10, Memory Subsystem](#).

26.4.7.3 XIP Memory

The ROM code can boot directly from XIP booting devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 2 Gb (256MB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 48 MHz.
- The booting device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is monitored according to the sys_boot configuration pins.

Depending on the sys_boot option, the GPMC can be configured to use the wait signal connected to the gpmc_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc_wait0 is low. Wait monitoring is used with memories that require a long time for initialization after reset, or that must pause while reading data. An example of such memory is DiskOnChip.

For an XIP memory booting, no user intervention is needed; the following steps are described for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next booting device.

Booting from an XIP booting device consists of the following steps:

1. Configure the GPMC for XIP booting device access.
2. Verify that the CH is present at address 0x0800 0000. If it is, copy the entire sector (512 B) to internal RAM and execute the CH.
3. Set the image location:
 - 0x0800 0000 if the CH is not found
 - 0x0800 0200 if the CH (512 bits) is found
4. Verify that a bootable image is at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

26.4.7.3.1 GPMC Initialization

[Table 26-30](#) describes the timing settings of GPMC set for XIP and other address-data accessible booting devices, like DiskOnChip or OneNAND/Flex-OneNAND. [Table 26-30](#) is included for debug information.

Table 26-30. XIP Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (where i = 0...7)	Reset Value
Write cycle time	17	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11.	0x11

26.4.7.4 NAND

NAND flash memory is not an XIP booting device; it requires shadowing before the code can be executed. ROM code support for the NAND flash booting devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 64 Mb (8MB)
- x8 and x16 bus width
- Small page size (512 bytes + 16 bytes), large page size (2048 bytes + 64 bytes), and very large page size (4096 bytes + 128 bytes)
- Chip enable (CE) don't care booting devices only
- Single level cell (SLC) and multilevel cell (MLC) devices
- Device identification is based on standard identification data or ID2 protocol.
- One-bit error checking and correction (ECC) is used to protect a 512-byte sector.
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 48 MHz.
- The booting device is connected to CS0.
- The wait pin signal gpmc_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for image. Block size depends on the booting device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next booting device for booting.

26.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, booting device detection with parameter determination, and bad block detection/verification.

- GPMC initialization

The GPMC interface is configured so that it can access NANDs. Because NANDs do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the booting device parameters are determined. [Table 26-31](#) shows the GPMC configuration used during NAND boot. [Table 26-31](#) is included for debug information.

Table 26-31. NAND Timing Parameters

Parameter	Value [Clock Cycles]	Register Initialization (where i = 0...7)	Reset Value
Write cycle time	20	The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x14.	0x11
Read cycle time	20	The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x14.	0x11
CS low time	0	The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x0.	0x1

Table 26-31. NAND Timing Parameters (continued)

Parameter	Value [Clock Cycles]	Register Initialization (where i = 0...7)	Reset Value
OE low time	5	The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x5.	0x3
OE high time	16	The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10.	0x10
WE low time	3	The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3.	0x3
WE high time	15	The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF.	0x10
Data latch time	14	The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xE.	0xF

- Booting device detection and parameters

The ROM code must first identify the NAND type connected on the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND booting device is reset and its status is polled until it is ready for operation, then the Read ID command is issued. If the Read Device ID is recognized as a supported booting device, the booting device parameters are extracted from an internal ROM code table. [Table 26-32](#) lists the supported NAND devices.

Table 26-32. Supported NAND Devices

Capacity	Device ID	Bus Width	Page Size in Bytes
64Mb	E6h	8	512
128Mb	33h	8	512
128Mb	73h	8	512
128Mb	43h	16	512

8Gb	D3h	8	2048 (4096)
8Gb	B3h	16	2048 (4096)
8Gb	C3h	16	2048 (4096)
16Gb	A5h	8	2048 (4096)
16Gb	D5h	8	2048 (4096)
16Gb	B5h	16	2048 (4096)
16Gb	C5h	16	2048 (4096)
32Gb	A7h	8	2048 (4096)
32Gb	B7h	16	2048 (4096)
64Gb	A Eh	8	2048 (4096)
64Gb	B Eh	16	2048 (4096)

After retrieving parameters from the table, page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only NAND devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page NAND devices, but only if their size, according to [Table 26-32](#), is at least 2Gb. NAND devices smaller than 2Gb have the block size parameter set to 32KB when the page size is 512 bytes and to 128KB when the page size is 2048 bytes. [Table 26-33](#) shows the fourth ID data byte encoding used in the ROM code.

Table 26-33. Fourth NAND ID Data Byte

Item	Description	I/O Number							
		7	6	5	4	3	2	1	0
Page Size	512 bytes							0	0
	2048 bytes							0	1
	4096 bytes							1	0
	8192 bytes							1	1
Block Size	64KB			0	0				
	128KB			0	1				
	256KB			1	0				
	512KB			1	1				

The detection procedure is described in [Figure 26-16](#). If the device ID is not recognized, the ROM code tries to read ID2 from the booting device; the sequence is described in [Figure 26-17](#). The description of the ID2 data content is summarized in [Table 26-34](#). If the ROM code fails to identify booting device ID or ID2, it returns with FAIL. When the booting device is successfully detected, the ROM code changes the GPMC to 16-bit bus width if necessary.

- **Bad block detection/verification**

Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block. [Table 26-35](#) lists the validity status coding for the four NAND families.

Table 26-35. Bad Block Mark Locations in NAND Spare Areas

	Small Page NAND	Large Page NAND
8-bit NAND device Block invalid when any byte does not equal FFh	6th byte in 1st page	1st byte in 1st page
	6th byte in 2nd page	1st byte in 2nd page
16-bit NAND device Block invalid when any word does not equal FFFFh	1st word in 1st page	1st word in 1st page
	6th word in 1st page	1st word in 2nd page
	1st word in 2nd page	
	6th word in 2nd page	

Figure 26-18 shows the invalid block detection routine. The routine consists in reading spare areas and checking data according to the conditions listed in Table 26-35. The flags are used internally to give information about the validity of each block.

Figure 26-18. Bad NAND Invalid Block Detection

init-033

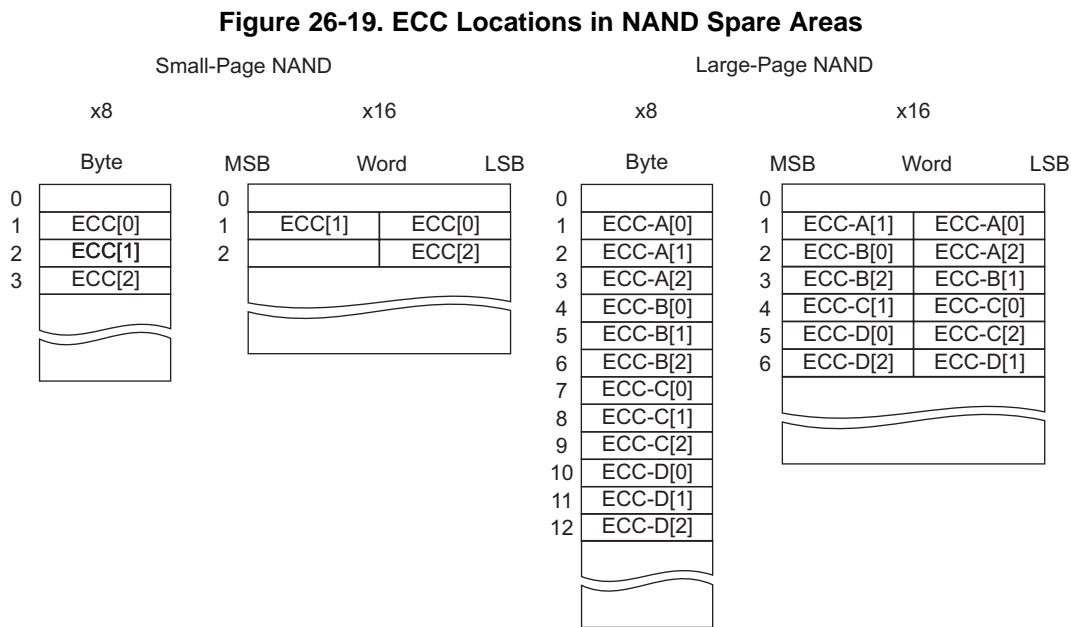

26.4.7.4.2 SLC NAND Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

Pages can contain errors caused by memory alteration (1 error bit/sector maximum). The ROM code uses ECC to correct those errors. The ECC algorithm, based on Hamming codes, is used on 512-byte sectors to generate 3 bytes. They are generated by the GPMC hardware on each read cycle. The computed ECC is compared to the ECC stored in the spare area of the corresponding page. Depending on the number of sectors per page (small pages and large pages), several ECC data are stored in the spare area of the page. If the computed ECC data and the stored ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct the error in the sector and returns the data, if successful. If there are uncorrectable errors, the ROM code returns with FAIL.

Figure 26-19 shows the ECC locations in NAND spare areas.

init-035

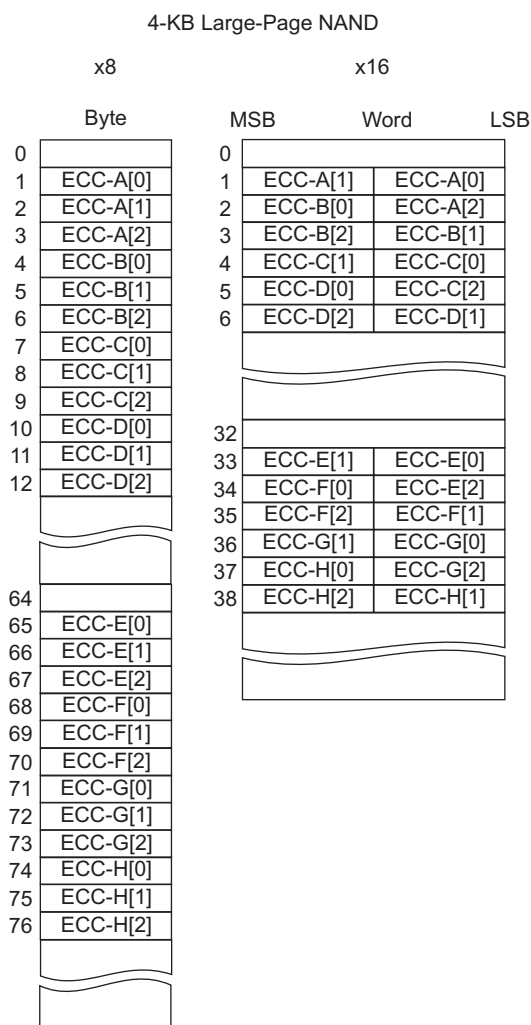

For large page NAND memories, the spare area contains four ECC sets, each for a 512-byte sector within the 2048-byte page. Sectors are tagged A, B, C, and D. Table 26-36 shows parity bit locations inside ECC bytes.

Table 26-36. Hamming Code Parity Bit Locations

Byte	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
ECC-x[0]	128-2	64-2	32-2	16-2	8-2	4-2	2-2	1-2
ECC-x[1]	128-1	64-1	32-1	16-1	8-1	4-1	2-1	1-1
ECC-x[2]	2048-1	1024-1	512-1	256-1	2048-2	1024-2	512-2	256-2

The 4-KB page NAND memories have eight ECC sectors tagged A to H. Figure 26-20 shows the spare area organization for such NANDs.

Figure 26-20. ECC Locations in 4-KB Page NAND Spare Areas

init-036

26.4.7.4.3 MLC NAND Read Sector Procedure

Multilevel cell (MLC) NANDs have a bigger bit error rate than single-level cell (SLC) NANDs. As a consequence, reading data from MLC NANDs requires a stronger error correction capability. Usually, NAND manufacturers recommend Bose-Chaudhuri-Hocquenghem (BCH) code, which can correct 4- or 8-bit errors in 512-byte data sectors. Because of the specific MLC implementation in the device, which is not fully hardware-based, ROM code cannot implement sector BCH encoding. Therefore, ROM code supports MLC booting using its proprietary error correction scheme. This error correction scheme is a combination of BCH, checksum, and redundancy techniques.

26.4.7.4.3.1 MLC Mode Detection

The ROM code verifies whether the block is programmed in MLC mode before reading data from each block. If MLC mode is detected, bad block verification is not performed and the block is considered to be valid. If a user intends a block to be omitted, it should be left erased, which consequently will cause the ROM code to fail in reading data and skipping to the next block.

MLC mode detection consists in reading fifteen 32-bit words of BCH-encoded data and checking whether they match the special encoding scheme described in the following section. The MLC mode is switched on if at least five words match the encoding scheme without errors.

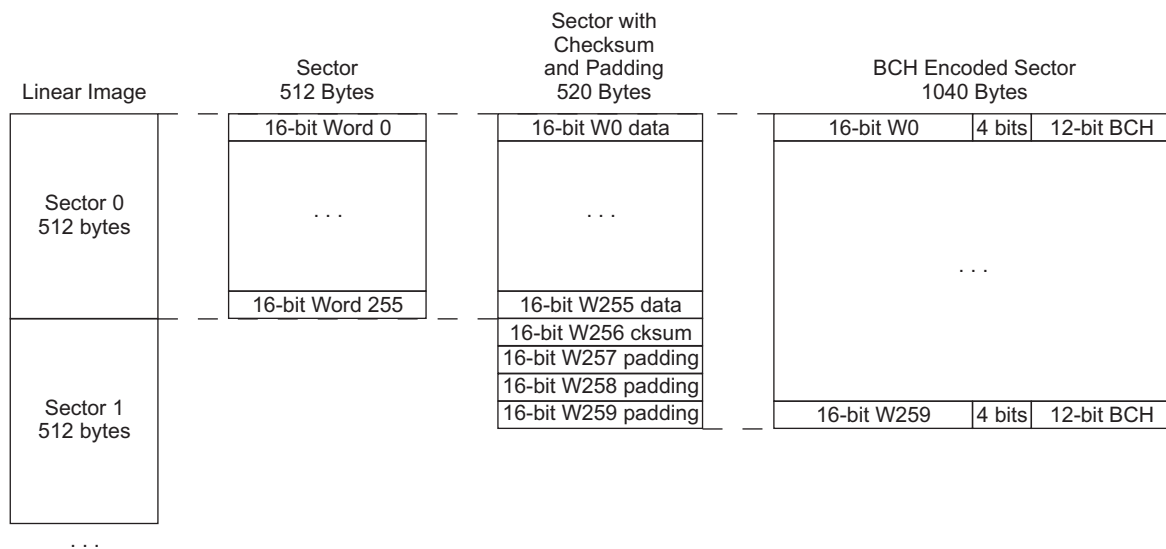

26.4.7.4.3.2 Data Encoding

The plain booting image must be formatted in a special way before being flashed:

1. Checksum modulo 16 is calculated, which means all 256 16-bit words are summed.
2. The checksum result and three empty words of padding are added at the end.
3. A sector is represented by 260 words, 16 bits each.
4. All 16-bit words are converted into 32-bit words by adding 12 bits of the BCH result and 4-bit zero padding.

Figure 26-21 shows how a sector of image data is processed.

Figure 26-21. MLC NAND Data Encoding

init-037

The BCH algorithm has the following characteristics:

- 32,20,2 – 32-bit message, 20-bit data, 2-bit error correction capability
- GF polynomial generator: $p(x) = X^6 + X^5 + 1$
- Generator polynomial: $g(x) = X^{12} + X^9 + X^8 + X^7 + X^4 + X^2 + 1$

The 2 bytes of data, that is a 16-b word, are encoded as follows:

Input byte stream: Byte0, Byte1, Byte3, Byte4, ...

Output byte stream: BCH[3..0], BCH[11..4]+0000b, Byte0, Byte1, BCH[3..0], BCH[11..4]+0000b, Byte3, Byte4, ...

26.4.7.4.3.3 Flash Layout

The 1040-encoded sectors are packed into a NAND space as shown in Figure 26-22. Encoded sectors are located serially, without gaps. The area named "Not Programmed" is not read by ROM code. Each encoded sector is put in twice. This redundancy is required to achieve the necessary booting reliability.

Figure 26-22. MLC NAND Page Layout

init-038

26.4.7.5 OneNAND/Flex-OneNAND

ROM code support for OneNAND/Flex-OneNAND devices has the following characteristics:

- Devices from 512Mb
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 48 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB.
- The ROM Code fully exploits the ECC controller embedded in the OneNAND/Flex-OneNAND devices themselves. The error code correction capability depends on this controller. ROM Code can support any existing and forecasted OneNAND/Flex-OneNAND devices.

The OneNAND/Flex-OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND/Flex-OneNAND memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

26.4.7.5.1 Initialization and OneNAND/Flex-OneNAND Detection

The initialization routine for OneNAND/Flex-OneNAND consists of two parts: GPMC initialization and booting device detection with parameter determination:

- GPMC initialization

The ROM code first initializes the GPMC interface the same way as for an XIP memory (that is,

asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled. See [Table 26-30](#).

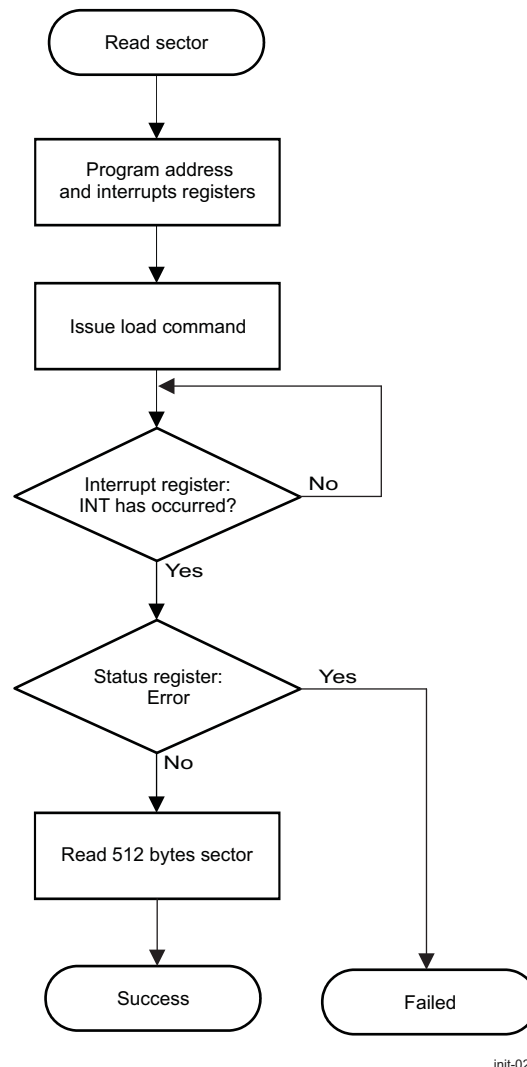

- OneNAND/Flex-OneNAND detection and parameters

The ROM code identifies a OneNAND/Flex-OneNAND device by reading the its identification data. There are two ways to read identification data: using serial commands and reading from fixed memory mapped registers. The ROM code reads identification data using both methods and compares the result. When the comparison passes, the ROM code assumes that the OneNAND/Flex-OneNAND device is connected. If the booting device is successfully recognized, the ROM code reads the booting device configuration (amount and size of data buffers) and configures it for asynchronous mode (default).

26.4.7.5.2 OneNAND/Flex-OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND/Flex-OneNAND device, the ROM code issues the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND/Flex-OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 26-23](#) shows this procedure.

Figure 26-23. OneNAND/Flex-OneNAND Read Sector

26.4.7.5.3 OneNAND/Flex-OneNAND Support Limitations

As described in [Section 26.4.7.5.1, Initialization and OneNAND/Flex-OneNAND Detection](#), the ROM code checks only the coherency of the device ID obtained by two different methods. There is no table of supported OneNANDs/Flex-OneNANDs in the ROM code. This removes any dependency of the ROM code on device IDs from different manufacturers. However, the driver works with the following assumption:

- Page size is assumed to be 2048 bytes, divided into four sectors of 512 bytes. In case of OneNAND/Flex-OneNAND, with pages of 4096 bytes, divided into eight sectors, users must program only the first sectors (sectors 0, 1, 2, 3) of each page. Sectors 4, 5, 6, and 7 of each page are not considered by the driver.

26.4.7.6 MMC/SD Cards

The ROM code supports MMC/SD cards, with some limitations:

- Supports MMC/SD cards compliant with the *Multimedia Card System Specification v4.2* from the MMCA Technical Committee and the *SD I/O Card Specification v 2 .0* from the SD Association. Includes high-capacity (size >2GB) cards: HC-SD and HC MMC
- 3-V power supply, 3-V I/O and 1.8-V I/O voltages on port 1
- Supports eMMC/eSD (1.8-V I/O voltage and 3.0-V Core voltage) on port 2. The external transceiver mode on port 2 is not supported.
- Initial 1-bit MMC mode, 4-bit SD mode
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: 20 MHz
- Only one card connected to the bus
- Raw mode, image data read directly from card sectors
- FAT12/16/32 support, with or without a master boot record (MBR).
- For a FAT (12/16/32)-formatted memory card, the booting file must not exceed 128 KB.
- For a raw-mode memory card, the booting image must not exceed 128 KB.

For MMC/SD memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Failure in MMC/SD card detection causes a return to the main booting procedure, which selects the next booting device for booting.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code. The MMC/SD specification defines two operating voltages for standard or HS cards. The ROM code supports only standard operating voltage range (3 V) (both modes supported).

The ROM code reads a booting file from the card file system and boots from it. [Figure 26-24](#) shows the complete procedure.

Figure 26-24. MMC/SD Booting

init-016

26.4.7.6.1 Initialization and MMC/SD Card Detection

The ROM code initializes the card connected on interface 1 using the standard high-voltage range (3.0 V) if a card is plugged in. If no card is present, the ROM code goes to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code searches for only one card connected on the bus. This is done using the CMD line common to the SD and MMC cards. The MMC and SD standards describe this phase as the initialization phase.

Figure 26-25 shows the MMC/SD detection procedure.

Figure 26-25. MMC/SD Detection Procedure

int-026

26.4.7.6.2 Read Sector Procedure

- Raw mode:

In raw mode, an image can be at offset 0 or 128KB and must not be bigger than 128KB. Raw mode is detected by reading sector 0 and sector 256. The content of these sectors is verified for the presence of a TOC structure. In the case of a GP device, a configuration header (CH) must be in the first sector followed by a GP header. The CH can be void (contains only a CHSETTINGS item for which the valid field is 0), as described in [Section 26.4.8.2, Configuration Header](#). Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is checked.
- File system handling:

The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can address sectors freely in the booting file space.

26.4.7.6.3 File System Handling

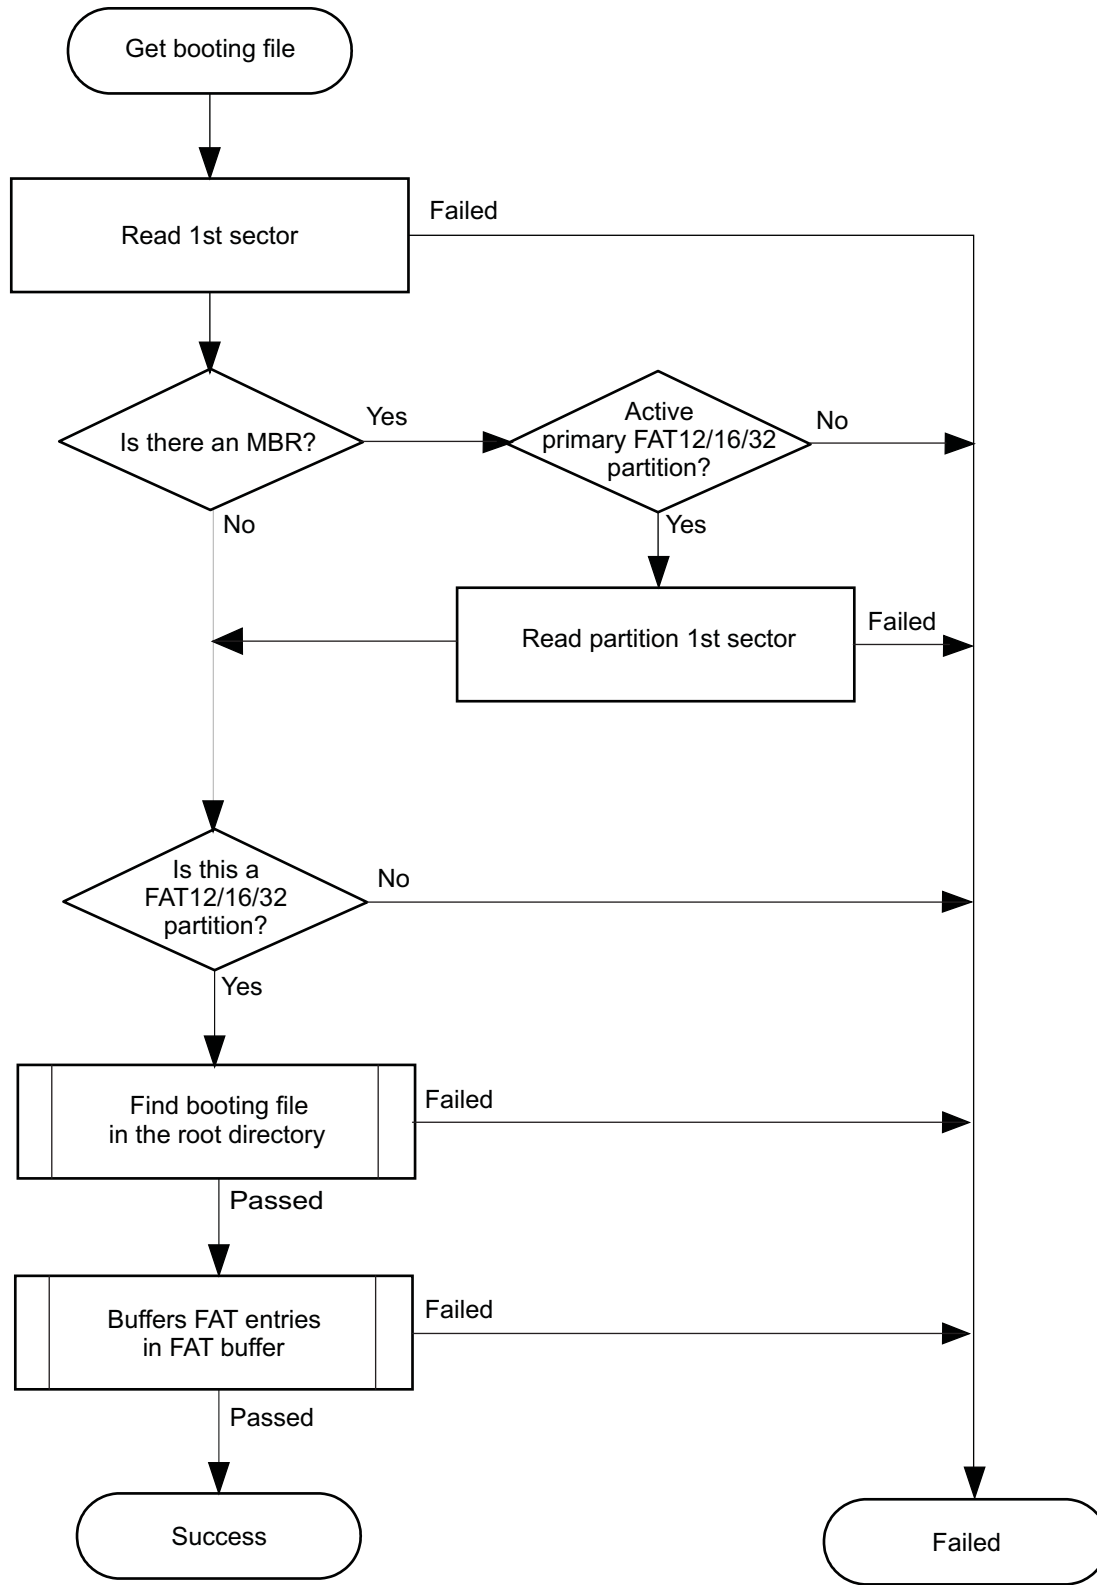

The MMC/SD cards can hold a file system that ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 26-26](#) shows the complete process.

Figure 26-26. SD/MMC Booting

init-027

26.4.7.6.3.1 MBR and FAT File System

This section describes the functions used by the ROM code to determine whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the booting device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 26-37](#); partition table entry is described in [Table 26-38](#).

Table 26-37. Master Boot Record Structure

Offset	Length (Bytes)	Entry Description
0000h	446	Optional code
01BEh	16	Partition table entry
01CEh	16	Partition table entry
01DEh	16	Partition table entry
01EEh	16	Partition table entry
01FEh	2	Signature (= 0xAA55)

Table 26-38. Partition Table Entry

Offset	Length (Bytes)	Entry Description	Value
0000h	1	Partition state	00h: Inactive 80h: Active
0001h	1	Partition start head	Hs
0002h	2	Partition start cylinder and sector	Cs[7:0]–Cs[9:8]–Ss[5:0]
0004h	1	Partition type	01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32
0005h	16	Partition end head	He
0006h	2	Partition end cylinder and sector	Ce[7:0]–Ce[9:8]–Se[5:0]
0008h	4	First sector position relative to the beginning of media	LBA _s = Cs.H.S+ Hs.S+ Ss–1
000Ch	4	Number of sectors in partition	LBA _e = Ce.H.S+ He.S+ Se–1 Nb s = LBA _e –LBA _s + 1

SD/MMC booting consists of the following steps:

Step 1. MBR detection:

The ROM code checks whether the MBR signature is present and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the type field. If the MBR entries are not valid or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- (a) If its type is set to 00h, all fields in the entry must be 00h.
- (b) The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

[Figure 26-27](#) shows the MBR detection procedure.

Figure 26-27. MBR Detection Procedure

init-028

Step 2. Get the MBR partition:

Once identified, the ROM code gets the partition using the procedure described in [Figure 26-27](#). The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or if there is more than one active partition, the test fails. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the booting device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, if another partition type is used (for instance, Linux FS) or if the partition is not valid, the ROM code returns with FAIL.

The FAT file system consists of:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. [Figure 26-28](#) shows the process to get the MBR partition.

Figure 26-28. Get MBR Partition

init-029

Step 3. Find the booting file:

When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$Cluster_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_NumFATs \cdot BPB_FATSz + Cluster \cdot BPB_SecPerCLus$$

init-E001

NOTE: For FAT12/16, BPB_FatSz is BPB_FatSz16.
For FAT32, BPB_FatSz is BPB_FatSz32.

NOTE: The BPB_HiddSec field can contain 0 even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, etc.). (See [Table 26-39](#).)

Table 26-39. FAT Directory Entry

Offset	Length [Bytes]	Name	Description
0000h	11	DIR_Name	Short Name (8 + 3)
000Bh	1	DIR_Attr	File Attributes: ATTR_READ_ONLY 01h ATTR_HIDDEN 02h ATTR_SYSTEM 04h ATTR_VOLUME_ID 08h ATTR_DIRECTORY 10h ATTR_ARCHIVE 20h ATTR_LONG_NAME ATTR_READ_ONLY ATTR_HIDDEN ATTR_SYSTEM ATTR_VOLUME_ID
000Ch	1	DIR_NTRes	Reserved. Set to 00h.
000Dh	1	DIR_CrtTimeTenth	Millisecond stamp at file creation
000Eh	2	DIR_CrtTime	Time file was created.
0010h	2	DIR_CrtDate	Date file was created.
0012h	2	DIR_LstAccDate	Last access date
0014h	2	DIR_FstClusHi	High word of the first cluster number of this entry
0016h	2	DIR_WrtTime	Time of last write
0018h	2	DIR_WrtDate	Date of last write
001Ah	2	DIR_FstClusLo	Low word of the first cluster number of this entry
001Ch	4	DIR_FileSize	File size in bytes

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR_LONG_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt, which is the total of 32-byte entries. Handling this directory is therefore straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. The way in which the FAT is handled is described in the following paragraph.

Step 4. Buffer FAT entries in the FAT buffer.

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB_FATsSz16 or BPB_FATsSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster located in the data area. One entry of

the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 26-40](#).

NOTE: For compatibility, cluster 0 and cluster 1 are not used for files, and those entries must contain FF8h and FFFh (for FAT12), FFF8h and FFFFh (for FAT16), and 0FFFFFFF8h and 0FFFFFFFh (for FAT32).

Table 26-40. FAT Entry Description

FAT12	FAT16	FAT32	Description
000h	0000h	00000000h	Free cluster
001h	0001h	00000001h	Reserved cluster
002h-FEFh	0002h- FFEFh	00000002h- 0FFFFFFEFh	Used cluster; value points to next cluster
FF0h-FF6h	FFF0h- FFF6h	0FFFFFFF0h- 0FFFFFFF6h	Reserved values
FF7h	FFF7h	0FFFFFFF7h	Bad cluster
FF8h-FFFh	FFF8h- FFFh	0FFFFFFF8h- 0FFFFFFFh	Last cluster in file

NOTE: FAT32 uses only 28 bits [27:0] of the 32 possible; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

26.4.7.7 DiskOnChip

The ROM code support for DiskOnChip devices has the following characteristics:

- DiskOnChip H3
- 1.8-V power supply
- Density from 256MB

The DiskOnChip contains an XIP part that can hold a boot image. In this case, the DiskOnChip is connected just like a regular NOR device, and uses the same procedure as for NOR, described in [Section 26.4.7.3, XIP Memory](#).

If booting determines that it must boot from DOC, the ROM code initializes the GPMC using standard asynchronous, 16-bit, multiplexed mode. The DOC device is then detected using the M-System driver. This proprietary driver handles all DiskOnChip protocols and identification. If the booting device cannot be identified, the ROM code returns a failed code. Otherwise, booting directly requests sectors from the M-System driver.

26.4.8 Image Format

26.4.8.1 Overview

An image has two major parts:

- An optional CH
- Software to execute

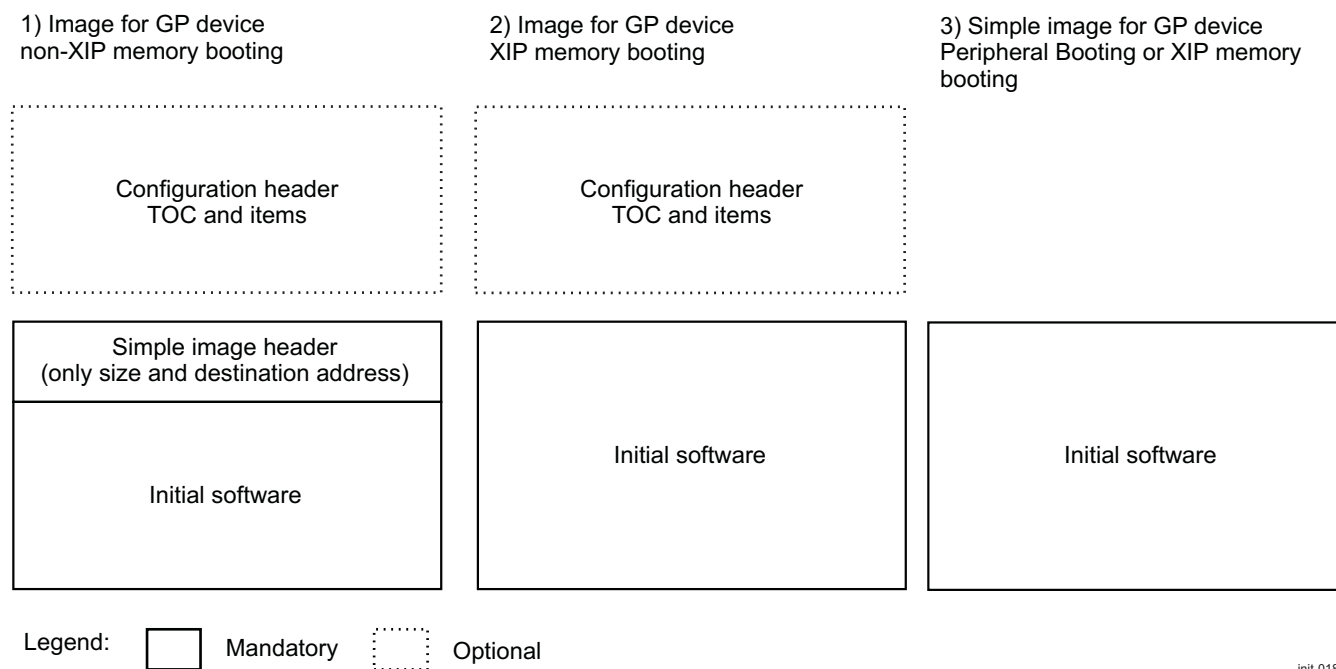

The CH, which is optional, can contain several parameters set by users to speed up booting. It is further described in the next section.

The mandatory part contains software that is loaded into the memory and executed.

An overview of the image formats is shown in [Figure 26-29](#). There are two image types:

- GP non-XIP memory booting: This image type is used for memories that require shadowing. The image must begin with a simple header that contains information about the size to copy and the destination. This format is described in [Section 26.4.8.3, Image Format for GP Devices](#).
- GP XIP memory booting and peripheral booting: A GP image on XIP memory contains only code. The first sector can contain CH. The GP peripheral booting image contains only code.

Figure 26-29. Image Format

26.4.8.2 Configuration Header

The CH is optional and is required only if the customer wants to use settings different from the ROM code defaults (for example, clock frequencies, SDRAM/double-data rate [DDR] SDRAM settings, GPMC settings). The CH can be present only when booting from a memory-type device (for example, CH is not supported when booting from UART or USB). Therefore, the CH contains settings only for memory booting.

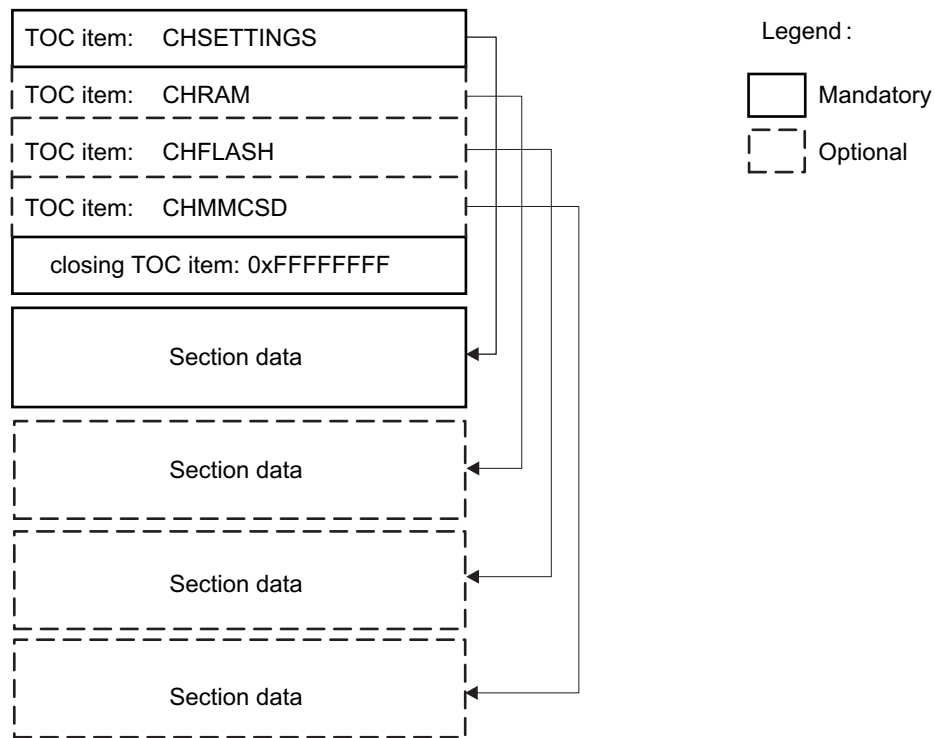

The CH can contain up to four parts:

- Settings: Clock settings (mandatory)
- RAM: SDRAM/DDR SDRAM interface settings
- FLASH: Flash interface (GPMC) settings
- MMC/SD: MMC/SDIO interface settings

The beginning of the CH is a table of contents (TOC) pointing to each item (see [Figure 26-30](#)). Each TOC item is a simple structure described in [Table 26-41](#). The complete CH (CH TOC and items) must fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Then, the TOC is identified and searched until a 0xFFFFFFFF offset is found. The CH is read and parameters are executed sequentially.

Figure 26-30. CH Format

init-019

Table 26-41. CH TOC Item

Offset	Field	Size (Bytes)	Description
0x0000	Start	4	Offset from the start address of TOC to the actual address of a section
0x0004	Size	4	Size of a section
0x0008	Reserved	4	Unused
0x000C	Reserved	4	Unused
0x0010	Reserved	4	Unused
0x0014	Filename	12	12-character name of a section, including the zero (0) terminator

26.4.8.2.1 CHSETTINGS

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the device clocking to some default settings as described in [Section 26.4.4.2, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clocking settings.

The fields are described in [Table 26-42](#). The clocking procedure, as well as the clocking setting structure are described in [Section 26.4.4.4, Software Booting Configuration](#).

The peripherals used during booting, that is, UART and USB are fed with 96 MHz and 48 MHz. This cannot be changed in the configuration header as it is only available for memory booting.

Table 26-42. CHSETTINGS

Offset	Field	Description
0000h	Section key	Key used for section verification: C0C0C0C1h
0004h	Valid	Enables/disables the section 00h: Disable

Table 26-42. CHSETTINGS (continued)

Offset	Field	Description
		Other: Enable
0005h	Version	Configuration header version 0001h Others: For future use
0006h	Reserved	
0008h	Clocking settings	Described in Table 26-12 , <i>Software Booting Configuration Structure</i> , starting from the FLAGS field

26.4.8.2.2 CHRAM

The CHRAM configuration header contains settings specific to SDRAM memory controller (SDRC). The fields are described in [Table 26-43](#). The ROM code does not configure the SDRC by default, as it cannot assume any external SDR/DDR SDRAM type. For more information, see [Section 10.2](#), *SDRC*, in [Chapter 10](#), *Memory Subsystem*.

Table 26-43. CHRAM

Offset	Field	Description CH – Used in CH Process CR – Used in Context Restore

0052h	SDRC_RFRCTRL_1 (MSB)	CH	CR
0054h	Reserved, write 0s for future compatibility		CR
0056h	Reserved, write 0s for future compatibility		CR
0058h	Flags	CH	CR
005A	Must be 0	CH	CR

26.4.8.2.3 CHFLASH

The CHFLASH configuration header contains settings specific to the GPMC. For more information, see [Section 10.1, GPMC](#), in [Chapter 10, Memory Subsystem](#). [Table 26-44](#) lists the fields. The ROM code configures the GPMC by default to these settings:

- CS0
- Asynchronous mode
- Wait input enabled
- Base address 08000000h

Table 26-44. CHFLASH

Offset	Field	Description
0000h	Section key	Key used for section verification: C0C0C0C3h
0004h	Valid	Enables/disables the section: 00h: Disable Others: Enable
0005h	Reserved	
0008h	GPMC_SYSCONFIG (LSB)	Register value
000Ah	GPMC_IRQENABLE (LSB)	
000Ch	GPMC_TIMEOUT_CONTROL (LSB)	
000Eh	GPMC_CONFIG (LSB)	
0010h	GPMC_CONFIG1_0	
0014h	GPMC_CONFIG2_0	
0018h	GPMC_CONFIG3_0	
001Ch	GPMC_CONFIG4_0	
0020h	GPMC_CONFIG5_0	
0024h	GPMC_CONFIG6_0	
0028h	GPMC_CONFIG7_0	
002Ch	GPMC_PREFETCH_CONFIG1	
0030h	GPMC_PREFETCH_CONFIG2 (LSB)	
0032h	GPMC_PREFETCH_CONTROL (LSB)	
0034h	GPMC_ECC_CONFIG	
0036h	GPMC_ECC_CONTROL	
0038h	GPMC_ECC_SIZE_CONFIG (LSB)	
003Ch	Enable_A1_A10	0: Do not change A1– A10 Others: Enable pins A1 – A10

26.4.8.2.4 CHMMCS D

The CHMMCS D configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see [Chapter 24, MMC/SD/SDIO Card Interface](#). [Table 26-45](#) lists the fields. The ROM code configures the MMCHS by default to these settings:

- 400-kHz clock during identification mode
- 19.2-MHz clock during data transfer mode

Table 26-45. CHMMCS D CH

Offset	Register Modified	Description
0000h	Section key	Key used for section verification C0C0C0C4h
0004h	Valid	Enables/disables the section 00h: Disable Other: Enable
0005h	Reserved	
0008h	MMCHS_SYSCTRL(MSB)	Register value
000Ah	MMCHS_SYSCTRL(LSB)	0xFFFFFFFF -> Do not update register. 1 -> 1 bit
000Ch	Bus width	2 -> 4 bits 4 -> 8 bits (on SD/MMC2 interface only) 0xFFFFFFFF -> Do not update register.

NOTE: The ROM code transmits a booting parameter structure to the initial software (see [Section 26.4.8.4, Image Execution](#)). This structure contains a field that indicates whether the configuration header sections have been correctly considered. For the CHMMCSO section, if all the section fields are set to 0xFFFFFFFF, regardless of the value of the VALID bit field, the booting parameters should indicate that the CHMMCSO section has not been executed.

26.4.8.3 Image Format for GP Devices

For a GP device, the image is simple and must contain a small header having the size of the software to load and the destination address of where to store it when a booting device is other than XIP. The XIP device image is even simpler and starts with executable code. [Table 26-46](#) describes the image format. The header is used only for memory booting. The peripheral booting image does not have a header and starts directly with executable code.

Table 26-46. GP Device Software Image

Field	Non-XIP Device	XIP Device	Size (Bytes)	Description
	Offset	Offset		
Size	0x0000	–	4	Size of the image
Destination	0x0004	–	4	Address where to store the image
Image	0x0008	0x0000	x	Image

26.4.8.4 Image Execution

The image is executed when the ROM code performs a branch instruction to the first executable instruction in the initial software. The execution address is the first word after the image header. After the branch, the ARM® runs in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting. [Table 26-47](#) shows the booting parameters structure.

Table 26-47. Booting Parameter Structure

Offset	Field	Size (Bytes)	Description
0x00	Booting message	4	Last received booting message
0x04	Current booting device	1	Code of booting device used for booting: 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x08: MMC/SD2 with hybrid connection 0x10: UART 0x11: HS USB Other: Reserved
0x05	Reserved	1	Reserved

Table 26-47. Booting Parameter Structure (continued)

Offset	Field	Size (Bytes)	Description
0x06	Reset reason	1	Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset (POR) [1]: Global software reset [2]: Reserved [3]: Reserved [4]: WDT2 reset [5]: Reserved [6]: External warm reset [7]: VDD1 voltage manager reset [8]: VDD2 voltage manager reset [9]: ICEPick™ reset [10]: ICECrusher™ reset Other bits: Reserved
0x07	CH flags	1	Configuration header sections flag. Each section is described by 1 bit. A set bit indicates that the section was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMC Other bits: Reserved
0x08	Device descriptor	4	Pointer to the device descriptor structure. This pointer is required when current booting device driver functions are called.

26.4.9 Tracing

Tracing in the public ROM code consists of a 64-bit vector in which each bit corresponds to a certain point of the ROM code execution flow. The tracing vector is divided into two 32-bit words. [Table 26-48](#) lists the location and organization of the tracing data in RAM. Tracing data is initialized at the beginning of startup.

There are two sets of tracing data: current trace information and tracing collected during the first ROM code run after a cold reset. This cold reset tracing is copied to its location during the tracing initialization of the second ROM code run after the cold reset run. These data can be used for debugging.

Table 26-48. Tracing Vector

Bit Number	Group	Meaning
0	General	Reset
1	General	ROM code C main
2	General	ROM code runs after the cold reset
3	Boot	Booting started
4	Memory boot	Memory booting started
5	Boot	No more booting device to check
6	Peripheral boot	Peripheral booting started
7	Boot	Booting message change booting device
8	Boot	Booting message skip per. booting
9	Reserved	Reserved
10	Memory boot	CH found
11	Memory boot	Image header correct
12	Peripheral boot	Device initialized
13	Peripheral boot	ASIC-ID sent

Table 26-48. Tracing Vector (continued)

Bit Number	Group	Meaning
14	Peripheral boot	Booting message received
15	Peripheral boot	Image received
16	Peripheral boot	Peripheral booting failed
17	Peripheral boot	UART
18	Peripheral boot	USB
19	Reserved	Reserved
20	Reserved	Reserved
21	Peripheral boot	NULL device
22	Execute	Image executed
23	Reserved	Reserved for non-GP devices
24	Reserved	Reserved for non-GP devices
25	Reserved	Reserved for non-GP devices
26	Reserved	Reserved for non-GP devices
27	Reserved	Reserved for non-GP devices
28	Reserved	Reserved for non-GP devices
29	Boot	Software booting configuration section 1 found
30	General	Software booting configuration clocking section found
31	Reserved	Reserved
32	Memory boot	Null device
33	Memory boot	XIP
34	Memory boot	NAND
35	Memory boot	OneNAND
36	Memory boot	DOC
37	Memory boot	MMC/SD2
38	Memory boot	MMC/SD1
39	Memory boot	XIP memory with wait monitoring
40	Reserved	Reserved
41	Reserved	Reserved
42	Reserved	Reserved

44	Reserved	Reserved
45	Reserved	Reserved
46	Reserved	Reserved
47	Memory boot	No known NAND was detected.
48	Memory boot	MLC NAND image was detected.
49	Memory boot	NAND boot was attempted from block 0.
50	Memory boot	NAND boot was attempted from block 1.
51	Memory boot	NAND boot was attempted from block 2.
52	Memory boot	NAND boot was attempted from block 3.

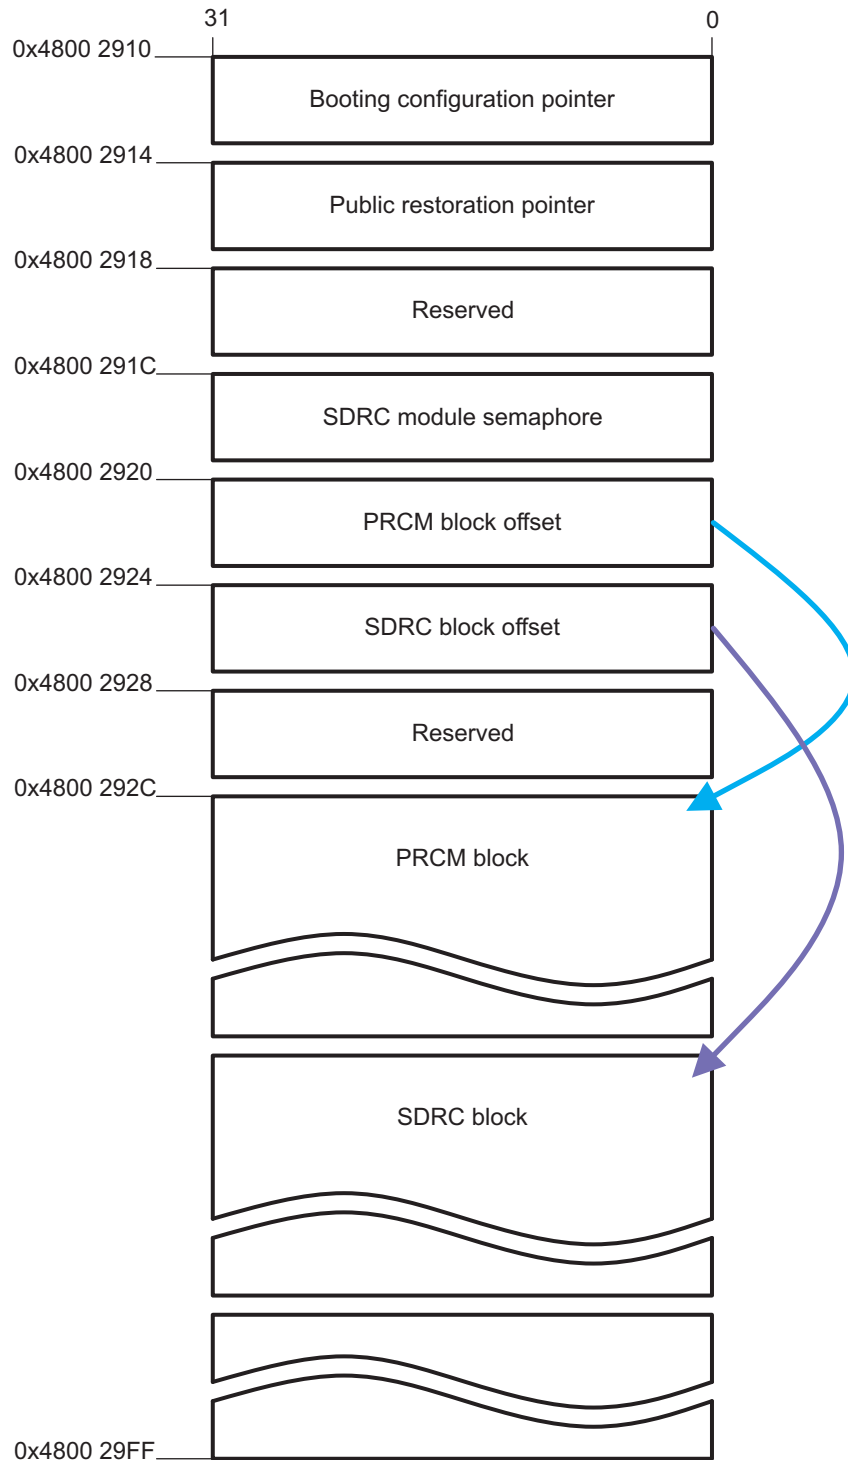

26.5 Wake-Up Booting by ROM Code

In CORE OFF power state, all configurations outside the WKUP power domain are reset and must be restored to restart the system in the condition it was in before being stopped. After an MPU and CORE power domain wake-up reset, the ROM code restores the SDRC and clock settings to allow a jump to a public restore function. This public restore function is specifically implemented by users to restore their own hardware and software environments. Users must set the public restore function address in the public restore pointer field of the CONTROL_SAVE_RESTORE_MEM structure.

The CONTROL_SAVE_RESTORE_MEM memory of the SCM saves and restores mandatory information to automatically reconfigure the SDRC and PRCM registers. The SDRC and clock registers must be saved by users in the respective structures (see [Table 26-50](#) and [Table 26-51](#)) in the SCM (scratchpad memory) before going to off mode to be automatically restored on wake-up boot by the ROM code.

The size of CONTROL_SAVE_RESTORE_MEM is 240 bytes starting at the hardware physical address 0x48002910 to 0x480029FF. [Figure 26-31](#) shows the memory format that must be obeyed to handle the context restoration.

Figure 26-31. CONTROL_SAVE_RESTORE_MEM Format

init-021

Table 26-49. CONTROL_SAVE_RESTORE_MEM Field Definitions

Field Name	Size	Description
Booting Configuration Pointer	32 bits	Address of public booting information used after a software reset
Public Restore Pointer ⁽¹⁾	32 bits	Address of the public restore function to branch to when exiting a wake-up reset boot

⁽¹⁾ Field to be set by users

Table 26-49. CONTROL_SAVE_RESTORE_MEM Field Definitions (continued)

Field Name	Size	Description
SDRC Module Semaphore ⁽²⁾	32 bits	Semaphore used for accessing the SDRC module
PRCM Block Offset ⁽¹⁾	32 bits	Offset of the PRCM configuration in the control save restore memory. Set 0x0 to not use this block. When the block is used the minimum allowed value is 0x18.
SDRC Block Offset ⁽¹⁾	32 bits	Offset of the SDRC configuration in the control save restore memory. Set 0x0 to not use this block. When the block is used the minimum allowed value is 0x18.

26.6 Debug Configuration

26.6.1 Overview

This section provides information for using a debugger on the public ARM Cortex™-A8 in the device. The debug capability is accessible through the JTAG interface with a limited number of pins.

26.6.2 JTAG Port Signal Description

The target debug interface of the device uses the five standard IEEE 1149.1 (JTAG) signals (nTRST, TCK, TMS, TDI, and TDO), a return clock (RTCK) to meet the clocking requirements of the ARM968 processor, and two instrumentations pins (EMU0, EMU1). [Table 26-52](#) lists the debug POR signals.

Table 26-52. Debug POR Signals

Pin	Type ⁽¹⁾	Name	Description
jtag_ntrst	I	Test logic reset	When asserted (active low), causes all test and debug logic in the device to be reset with the IEEE 1149.1 interface
jtag_tck	I	Test clock	Test clock used to drive an IEEE 1149.1 test access port (TAP) state-machine and logic. Depending on the emulator attached to the device, this is a free-running clock or a gated clock, depending on RTCK monitoring.
jtag_rtck	O	Returned test clock	Synchronized TCK. Depending on the emulator attached to device, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
jtag_tms	I	Test mode select	Directs the next state of the IEEE 1149.1 TAP state-machine
jtag_tdi	I	Test data input	Scan data input to the device.
jtag_tdo	O	Test data output	Scan data output of the device.
jtag_emu0	I/O	Emulation 0	Channel 0 trigger: Boot mode
jtag_emu1	I/O	Emulation 1	Channel 1 trigger: Boot mode

⁽¹⁾ I = Input; O = Output

To reduce power consumption, the power domain that contains the debug logic can be switched off in normal operating mode.

CAUTION

Before starting the debugger, the DEBUG power domain must be activated by applying a minimum of 10 TCK pulses to the device after nTRST is pulled high. To prevent the JTAG_TMS pin from floating when the EMU power domain is off, an external pullup (10 kΩ) must be added.

26.6.3 Initial Scan Chain Configuration

The GP ports that can provide access to many test support functions built into the device (including the test logic defined by the IEEE 1149.1 standard) are the TAP.

The first level of the debug interface that sees the scan controller is the TAP router module.

The debugger can configure the TAP router to link to 16 TAP controllers serially or to scan one TAP controller individually without disrupting the instruction register (IR) state of the other TAPs. The initial scan chain configuration of the device is determined from the level of the EMU0 and EMU1 pins on the release of POR. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins must be pulled high at POR to configure the initial scan chain of the device to the TAP router-only mode. In the TAP router-only configuration, no secondary TAPs are selected. The TAP router is the only TAP between the device-level TDI and TDO.

The router TAP has an IR length of 6 bits. This is the recommended boot mode. The third-party debugger must assume that the TAP router is the only TAP between TDI and TDO at boot.

26.6.4 Adding TAPs to the Scan Chain

The TAP router must be programmed to add TAPs to the scan chain (used in Design For Test). The following JTAG scans must be completed before the CoreSight debug access port (DAP) is added to the scan chain. CoreSight is the on-chip debug and trace ARM technology. IR and DR are the instruction register and the data register, respectively.

```
## Function : Update the JTAG preamble and post-amble counts. Parameter : The IR pre-
amble count is '0'. Parameter : The IR post-amble count is '0'. Parameter : The DR pre-
amble count is '0'. Parameter : The DR post-
amble count is '0'. Parameter : The IR main count is '6'. Parameter : The DR main count is '1'.
## Function : Do a send-
only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-ir'. Parameter : The JTAG destination state is 'pause-
ir'. Parameter : The bit length of the command is '6'. Parameter : The send data value is
'0x00000007'. Parameter : The actual receive data is 'discarded'. ## Function : Do a send-
only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-dr'. Parameter : The JTAG destination state is 'pause-
dr'. Parameter : The bit length of the command is '8'. Parameter : The send data value is
'0x00000089'. Parameter : The actual receive data is 'discarded'. ## Function : Do a send-
only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-ir'. Parameter : The JTAG destination state is 'pause-
ir'. Parameter : The bit length of the command is '6'. Parameter : The send data value is
'0x00000002'. Parameter : The actual receive data is 'discarded'. ## Function : Embed the POR
address in next command. Parameter : The POR address field is '0x0f000000'. Parameter : The POR
address value is '3'. ## Function : Do a send-
only JTAG IR/DR scan. Parameter : The route to JTAG shift state is 'shortest transition'.
Parameter : The JTAG shift state is 'shift-dr'. Parameter : The JTAG destination state is 'pause-
dr'. Parameter : The bit length of the command is '32'. Parameter : The send data value is
'0xa3002108'. Parameter : The actual receive data is 'discarded'. ## Function : Do a send-
only all-ones JTAG IR/DR scan. Parameter : The JTAG shift state is 'shift-
ir'. Parameter : The JTAG destination state is 'run-
test/idle'. Parameter : The bit length of the command is '6'. Parameter : The send data value is
'all-
ones'. Parameter : The actual receive data is 'discarded'. ## Function : Wait for a minimum
number of TCLK pulses. Parameter : The count of TCLK pulses is '10'. ## Function : Update the
JTAG preamble and post-amble counts. Parameter : The IR pre-
amble count is '0'. Parameter : The IR post-amble count is '6'. Parameter : The DR pre-
amble count is '0'. Parameter : The DR post-
amble count is '1'. Parameter : The IR main count is '4'. Parameter : The DR main count is '1'.
```

After the DAP is added to the scan chain, the debugger can communicate with the Cortex-A8 processor.

26.6.5 Debugger Address Space

The CoreSight components are interfaced with the TAP router through the DAP. As recommended by the CoreSight architecture, the DAP is directly interfaced to the device bus. The debugger can directly access the entire memory space without requiring the processor to enter debug state and be programmed with a load or store instruction. [Table 26-53](#) lists the modules that are mapped to the DAP address, and the address space detail.

Table 26-53. Debugger Address Space

Start Addr (Hex)	End Addr (Hex)	Size	Description
0x5401 0000	0x5401 0FFF	4KB	ARM embedded trace macrocell (ETM) module
0x5401 1000	0x5401 1FFF	4KB	Cortex-A8 module
0x5401 9000	0x5401 9FFF	4KB	Trace port interface unit (TPIU)
0x5401 B000	0x5401 BFFF	4KB	ARM embedded trace buffer (ETB) module

The DBGEM signal on the Cortex-A8 is driven by setting bit 13 at address 0x5401 D030 in the DAP-APB address space.

Debug and Emulation

This chapter describes the debug and emulation module on the device.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see [Section 1.5, AM/DM37x Family](#) and your device-specific data manual. In unavailable modules and features, the memory area is reserved, read is undefined, and write can lead to unpredictable behavior.

27.2 ICEPick Module	3600
27.3 SDTI Module	3620
27.4 Emulation Pin Manager	3652

27.1 Debug and Emulation Overview

This chapter presents an overview of the debug and emulation hardware features.

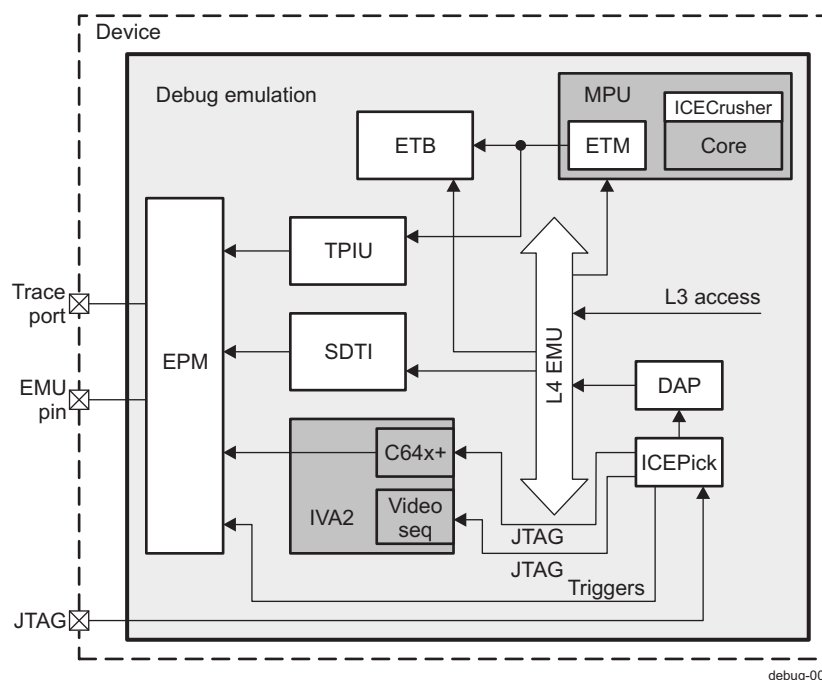

27.1.1 Debug and Emulation Overview Features

Debugging a system containing multiple embedded processors involves an environment that connects high-level debugging software, executing on a host computer, to a low-level debug interface supported by the device. Between these levels is an emulator, which facilitates communication between the host debugger and the emulation logic on the device.

Debug and emulation is a combination of hardware and software that connects the host debugger to the target device. It uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG commands and scans that execute the core hardware.

Figure 27-1 shows the module used in the device for debug and emulation.

Figure 27-1. Debug and Emulation Hardware in the Device

The debug software and hardware components lets the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors (the ICEPick™ feature is not supported by all the platform processors)
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors.

27.1.2 Debug and Emulation Functional Description

27.1.2.1 ICEPick

The device contains multiple processors, each of which has a JTAG test access port (TAP) embedded in the processor. The ICEPick module manages these TAPs and the power, clock, and reset controls for the module that has the TAP. At its root, ICEPick is a scan path linker that allows the scan controller to selectively choose which subsystem TAPs are accessible through the device level debug port. ICEPick is configured through its IEEE 1149.1 JTAG TAP controller.

The ICEPick module is described in [Section 27.2, ICEPick Module](#).

27.1.2.2 SDTI

The system debug trace interface (SDTI) is a component that implements the device system trace. The SDTI module provides real-time software tracing functionality to the device. It generates operating system monitor messages that are encoded as defined in the custom protocol.

NOTE: The custom protocol is not MIPI® compliant.

Messages let software provide crucial information, thus providing a high level of visibility on system behavior (task entry, procedures calls, system status, test signatures, and memory allocation); 256 message channels, which can be allocated between software components, are available.

The SDTI implements only trace export from the device to a remote PC through an emulator box. There is no receive path feature in the SDTI. A standard asynchronous serial port (universal asynchronous receiver/transmitter [UART], 8 data bits, 1 stop-bit, no parity) can be used as a back-channel to send emulation-related control requests and data back to the device.

The SDTI is described in [Section 27.3, SDTI Module](#).

27.1.2.3 EPM

The emulation pin manager (EPM) manages emulation pin multiplexing to the application pin manager. It allows the selection of an emulation interface to be routed to the device boundary pads.

The EPM is described [Section 27.4, Emulation Pin Manager](#).

27.1.2.4 DAP

The debug access port (DAP) enables the external debugger to directly access the entire memory space of the device without requiring the processor to enter the debug state and be programmed with a load or store instruction.

The DAP directly interfaces with the device level 4 (L4) EMU interconnect. The DAP is attached to the last ICEPick secondary TAP and translates JTAG transactions into interconnect transactions.

For more information about the DAP, see the documentation section at <http://www.arm.com/>.

27.1.2.5 ETM

The embedded trace macrocell (ETM) generates a real-time trace to the trace port interface unit (TPIU) or is stored in the embedded trace buffer (ETB).

For more information about the ETM, see the documentation section at <http://www.arm.com/>.

27.1.2.6 ETB

The ETB stores the trace generated by the ETM. The trace can then be read by the JTAG interface.

For more information about the ETB, see the documentation section at <http://www.arm.com/>.

27.1.2.7 TPIU

The TPIU is used to export the ETM trace at the device pads.

For more information about the TPIU, see the documentation section at <http://www.arm.com/>.

27.2 ICEPick Module

This section describes the ICEPick module in the device.

27.2.1 ICEPick Overview

System-on-a-chip designs typically have multiple processors, each of which has a JTAG TAP embedded in the processor. The ICEPick module manages these TAPs and the power, clock, and reset controls for modules that have TAPs. At its root, ICEPick is a scan path linker that lets the scan controller selectively choose which subsystem TAPs are accessible through the device level debug port. ICEPick is configured through its IEEE 1149.1 JTAG TAP controller. [Figure 27-2](#) is an overview of the ICEPick module in the device.

Figure 27-2. ICEPick Overview

ICEPick supports:

- Individually selecting one or more of the TAPs for scan without disrupting the state of other TAPs
- Management of the reset to many processors
- Management of the power and clock of many power domains

The ICEPick module has the following characteristics:

- IR length of 6 bits
- DR length of 1 in bypass mode
- DR length from 1 to 32 (see [Section 27.2.4.5, ICEPick Instructions](#))
- Boot mode controlled by device pins (see [Section 27.2.2, ICEPick Environment](#))

27.2.2 ICEPick Environment

The ICEPick module is connected to the JTAG interface in the device. The JTAG interface has six pins plus two pins for selecting ICEPick boot mode (see [Table 27-1](#)).

Table 27-1. JTAG Pins

PAD	Name	Width	Type ⁽¹⁾	Reset Value	Description
jtag_ntrst	Test Logic Reset	1	I	HiZ	When asserted (active low), causes all test and debug logic in the device to be reset along with the IEEE 1149.1 interface.

⁽¹⁾ I = Input; O = Output

Table 27-1. JTAG Pins (continued)

PAD	Name	Width	Type ⁽¹⁾	Reset Value	Description
jtag_tck	Test Clock	1	I	HiZ	This is the test clock used to drive an IEEE 1149.1 TAP state-machine and logic. Depending on the emulator attached to the device, this is a free-running clock or a gated clock, depending on RTCK monitoring.
jtag_rtck	Returned Test Clock	1	O	0	Synchronized TCK. Depending on the emulator attached to the device, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK.
jtag_tms	Test Mode Select	1	I	HiZ	Directs the next state of the IEEE 1149.1 TAP state-machine
jtag_tdi	Test Data Input	1	I	HiZ	Scans data input to the device
jtag_tdo	Test Data Output	1	O	HiZ	Scans data output of the device
jtag_emu0	Emulation 0	1	IO	HiZ	Channel 0 trigger – boot mode – HS-RTDX – trace port
jtag_emu1	Emulation 1	1	IO	HiZ	Channel 1 trigger – boot mode – HS-RTDX – trace port

For more information about ICEPick boot modes, see [Section 27.2.4.4](#).

The ICEPick module has a TAP state-machine consistent with the IEEE 1149.1 specification. For more information about TAP states, see [Section 27.2.4.3](#).

27.2.3 ICEPick Integration

The ICEPick module is in the EMU power domain.

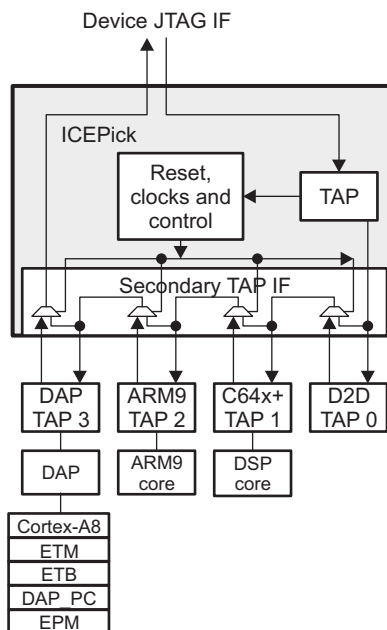

The ICEPick module use only JTAG clocks (jtag_tck and jtag_rtck). These clocks are external clocks and are not managed by the device power, reset, and clock management (PRCM) module.

27.2.4 ICEPick Functional Description

27.2.4.1 ICEPick Block Diagram

Figure 27-3 is the block diagram of the ICEPick module with the four external (secondary) TAPs connected to the ICEPick scan chain.

Figure 27-3. ICEPick Overview

27.2.4.2 ICEPick Secondary Debug TAPs

Table 27-2 shows the secondary debug TAPs connected to the ICEPick scan chain. The TAP number shows the position of the TAP in the scan chain and the SDTRj register (see Table 27-23) used to get access to control and status for this TAP. The ICEPick internal TAP can also be referenced as the primary TAP; it is always in the first position in the scan chain (ICEPick TAP input is connected to the device jtag_tdi pin).

Table 27-2. Secondary Debug TAP Mapping

Secondary JTAG port	CoreSight	TAP No.	Modules Accessed Through That JTAG Port
D2D	No	0	Die-to-die interface
IVA	No	1	C64x+/ICEMaker
ARM968™	No	2	ARM968/ICECrusher™ – IVA Sequencer
DAP	Yes	3	MPU/ICECrusher – CS / ETM11 / PSA
	Yes		ETB
	Yes		SDTI
	No		Clocks Management → L3 → L4_CORE
	No		Power Management → L4_EMU → L4_WKUP
Reserved	No	4–15	Reserved

27.2.4.3 ICEPick TAP states

The TAP consists of:

- 32-bit device ID register
- 1-bit bypass register
- 6-bit instruction register (IR)

Figure 27-4 shows ICEPick TAP states. In the figure, TMS corresponds to the jtag_tms input pin.

Figure 27-4. TAP State Transitions

27.2.4.4 ICEPick Boot Modes

The initial configuration of ICEPick is determined from the level of `jtag_emu0` and `jtag_emu1` at POR release. At POR, `jtag_emu0` and `jtag_emu1` are automatically configured as inputs.

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between the device level TDI and TDO. This is the recommended boot mode (`jtag_emu0` and `jtag_emu1` are set at 1).

The device can boot to invoke wait-in-reset mode. This mode keeps the device microprocessor unit (MPU) in wait-in-reset mode until the ICEPick module disables the MPU reset through a JTAG by writing the `SDTRj` register (see [Table 27-23](#)).

When TCK direct boot mode is used, the ICEPick clock voting logic is bypassed. TCK is driven onto each secondary TAP.

[Table 27-3](#) shows the values of `jtag_emu0` and `jtag_emu1` used to select different boot modes.

Table 27-3. ICEPick Boot Mode

<code>jtag_emu1</code>	<code>jtag_emu0</code>	TAPs in the TDI → TDO Path	Other Effects
0	0	ICEPick + D2D	Boundary scan stacked die
0	1	ICEPick	TCK direct
1	0	ICEPick	Wait-in-reset
1	1	ICEPick	

27.2.4.5 ICEPick Instructions

27.2.4.5.1 ICEPick Instruction List

ICEPick TAP supports the instructions listed in [Table 27-4](#). All unused TAP controller instructions default to the bypass register. Several instructions are reserved for extensions to the ICEPick opcodes.

Table 27-4. ICEPick Instructions

IR	ICEPick Instruction	Extended Instruction	Access
000000	BYPASS	Not available	Always-open
000001	Reserved	Not available	Always-open

111111	BYPASS	BYPASS	Always-open

27.2.4.5.2 Instruction Register Scan Path and State

Capture IR state: The binary value 000001b is loaded into the data shift register.

Shift IR state: The IR shift section of the data shift register is selected as the serial path between the ICEPick TDI and TDO. The value captured at Capture IR is shifted out during Shift IR, with the least significant bit (LSB) first, while a new instruction is shifted in, also with the LSB first.

Update IR state: The value in the data shift register is loaded into the instruction register so it becomes the current instruction.

Test Logic Reset state: On TAP reset, the IDCODE becomes the current instruction. When the ICEPick TAP reaches the Test Logic Reset state, the IR register is automatically loaded with the IDCODE instruction.

27.2.4.5.3 Data Shift Register Scan Path and State

27.2.4.5.3.1 IDCODE Instruction

Description: The IDCODE instruction specifies that the DR shift path is 32 bits long. This path provides a way to export the value of the identification (ID) register in the device. The ID register is a 32-bit register that specifies the manufacturer, part number, and version of the component (see [Table 27-10](#)). The use of this instruction has no effect on the operation of the on-chip system logic.

Capture DR state: The 32-bit ID code of the device is loaded into the data shift register during the Capture DR state.

Shift DR state: The value captured is shifted out during the Shift DR TAP state with the LSB first, while the value of jtag_tdi is shifted into the most-significant bit (MSB) of the data shift register. Data is shifted from the MSB to the LSB.

Update DR state: The shifted-in data is ignored in the Update DR state.

The device ID can be determined following the generation of the Test Logic Reset TAP state. The Test Logic Reset TAP state causes all JTAG-compliant devices to load the IR with an IDCODE or a BYPASS instruction. These two opcodes provide a different first output (1 for IDCODE; 0 for BYPASS) during the first Shift DR state after the TRST, provided the DR Scan occurs without an intervening IR scan.

Therefore, examination of the first bit of data that is shifted out of a component during a test data scan sequence immediately after exiting the Test Logic Reset state shows whether a device ID register is included in the design.

When test data register scanning is entered in this way, the serial path at the board level includes:

- The device ID registers of components that provide them
- The bypass registers of components that do not include a device ID register

Examination of the first bit of data shifted out of a component as a result of the above interrogation sequence identifies the data as coming from the bypass bit or a device ID register. ICEPick exports a device ID for this sequence, thus providing a way to retrieve and identify the device ID.

27.2.4.5.3.2 ICEPICKCODE Instruction

Description: The ICEPICKCODE instruction specifies that the DR shift path is 32 bits long. This path provides a way to export the ICEPick identification (IPID) register (see [Table 27-12](#)). The IPID register is a 32-bit register that specifies the features and version of ICEPick. This ID register is for the ICEPick module and should not be confused with the ID register for the device or any other module. The use of this instruction has no effect on the operation of the on-chip system logic.

Capture DR state: The 32-bit ICEPick code is loaded into the data shift register during the Capture DR state.

Shift DR state: The value captured is shifted out during the Shift DR TAP state with the LSB first, while the value of `jtag_tdi` is shifted into the MSB of the data shift register. Data is shifted from the MSB to the LSB.

Update DR state: The shifted in data is ignored in the Update DR state.

27.2.4.5.3.3 USERCODE Instruction

Description: The USERCODE instruction specifies that the DR shift path is 32 bits long. This path provides a way to export the value of the user code (UC) register (see [Table 27-11](#)). The UC register is a 32-bit register that specifies the variant of a device. The use of this instruction has no effect on the operation of the on-chip system logic.

Capture DR state: The 32-bit UC register in the device is loaded into the data shift register during the Capture DR state.

Shift DR state: The value captured is shifted out during Shift DR TAP state with the LSB first, while the value of `jtag_tdi` is shifted into the MSB of the data shift register. Data is shifted from the MSB to the LSB.

Update DR state: The shifted-in data is ignored in the Update DR state.

27.2.4.5.3.4 BYPASS Instruction

Description: The IEEE 1149.1 specification mandates a BYPASS instruction and that the instruction decode must be an all-ones value equal in length to the instruction register length. All unused TAP controller instruction codes default to having the same characteristics as the BYPASS instruction.

The BYPASS instruction, and all instruction codes defaulting to the BYPASS instruction, specifies a DR shift path 1 bit long between the ICEPick TDI and TDO. This path provides a way to export the 0 used to differentiate bypass data from the data in the device ID register, if a DR scan is performed immediately following the Test Logic Reset TAP state.

Capture DR state: In the Capture DR state, 0 is loaded into the 1-bit shift path selected by this instruction.

Shift DR state: When the BYPASS instruction is the current instruction in the instruction register, serial data is transferred from TDI to TDO through the 1-bit bypass register while in the Shift DR state with a delay of one TCK cycle.

Update DR state: The shifted-in data is ignored in the Update DR state.

The BYPASS instruction is used when a scan controller wants to shift in data or commands to another TAP on the scan path without disturbing this TAP.

27.2.4.5.3.5 CONNECT_PUBLIC Instruction

Description: The CONNECT_PUBLIC instruction, in combination with the connect register, is used to enable many of the other IR instructions. Before being enabled, the instructions act as the BYPASS instruction.

The CONNECT_PUBLIC instruction specifies that the DR shift path is 8 bits long. This path provides a way to access the connect register, which is described in [Table 27-13](#).

Capture DR state: When the CONNECT instruction is in the IR, a DR scan scans through the 8 lower bits of the data shift register. Bit 7 is not part of the connect register (0 is used to read the register; 1 is used to write the register).

Shift DR state: When in the Shift IR state, the connect shift section of data shift register is selected as the serial path between the ICEPick TDI and TDO. The value captured at Capture DR is shifted out to ICEPick TAP TDO during Shift DR, with the LSB first. The value on `jtag_tdi` is shifted into the data shift register. Data is shifted from the MSB to the LSB.

NOTE: While the value is being scanned out, a new register access (read or write) can be scanned in.

Update DR state: On read and write, the scan chain is decoded at the Update DR state. The value of bit 7 determines whether the connect register is written at the Update DR state. If 1, the register is written.

27.2.4.5.3.6 CONNECT_PRIVATE

Description: The CONNECT_PRIVATE instruction, in combination with the private enable register, is used to enable extended TAP functions. The CONNECT_PRIVATE instruction is accessible only after the Connect Public scan sequence is complete.

The CONNECT_PRIVATE instruction specifies that the DR shift path is 1 bit in length. This path provides a way to access the private enable register.

Capture DR state: In the Capture DR state, the current value of Private_Enable is loaded into the 1-bit shift path selected by this instruction.

Shift DR state: When the CONNECT_PRIVATE instruction is the current instruction in the instruction register, serial data is transferred from TDI to TDO through the 1-bit Private_Enable register while in the Shift DR state with a delay of one TCK cycle.

Update DR state: The shifted-in data is latched in a temporary register in the Update DR state.

Run Test Idle state The data value in the temporary register is written to Private_Enable when the Run_Test_Idle state is reached.

The Private_Enable instruction is used to prevent extended TAP functions from being invoked until the connect sequence completes. This can be used to ensure test functions are held in reset, even though the chip-level test reset is no longer asserted.

27.2.4.5.3.7 ROUTER Instruction

Description: The ROUTER instruction specifies that the DR shift path is 32 bits long. This path provides a way to access the ICEPick TAP linking, status, and control registers. It provides accessibility to the secondary TAP controls for each TAP that ICEPick manages (see [Section 27.2.4.6.3.1, TAP_ROUTING_REG Description](#)).

The ROUTER instruction connects the ICEPick router scan path between TDI and TDO when doing a DR scan. This scan chain facilitates reading and writing of all ICEPick registers. All ICEPick functions are accessed through registers. The ROUTER instruction is used to read and write the registers.

NOTE: To use the ROUTER instruction, ICEPick must be in the connected state. Otherwise, this instruction acts like the BYPASS instruction.

Capture DR state: During the Capture DR state, the data shift register is inspected. The register specified by the block and register fields is read and the value is placed in the lower 24 bits of the data shift register.

NOTE: The current contents of the data shift register are those loaded by the previous scan. The register specified in DR scan $n-1$ is read during scan n . If an intervening IR scan occurs, the contents of the data shift register are unpredictable; therefore, a read of the register indicated in DR scan $n-1$ does not occur.

The write-failure (WF) bit is captured into the data shift register at bit 31. Once the value is captured, the WF flag is cleared.

Shift DR state: The 32-bit value captured is shifted out during the Shift DR TAP state with the LSB first, while the value of jtag_tdi is shifted into the MSB of the data shift register. Data is shifted from the MSB to the LSB.

The shifted-in value may contain a new register read or write request and the associated payload.

Update DR state: For a read or write, the scan chain is decoded during the Update DR state.

Figure 27-5 shows multiple read access in the ROUTER instruction.

Figure 27-6 shows multiple write access in the ROUTER instruction.

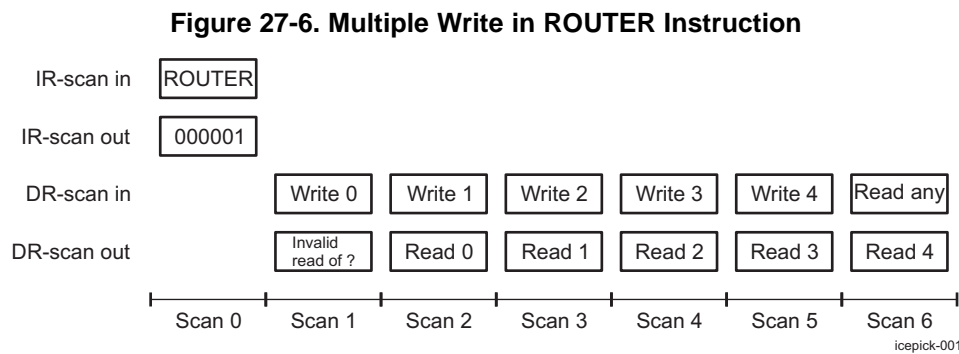

Figure 27-7 shows mixed read and write access in the ROUTER instruction.

27.2.4.6 ICEPick Registers

ICEPick registers are accessed through the ICEPick TAP.

27.2.4.6.1 Registers

Table 27-5 shows the ICEPick registers.

Table 27-5. ICEPick Registers

Register	Name	Width	Number	Description
Data shift register	DSR	32	1	TAP data register
Instruction register	IR	6	1	TAP instruction register
Bypass register	BP	1	1	Used by the BYPASS instruction
Device identification register	TAPID	32	1	Device ID used with IDCODE
User code register	UC	32	1	User Code used with USERCODE
ICEPick identification	IPID	32	1	Version of ICEPick
Connect	CONNECT	8	1	Connect code
All 0s	ALL0S	24 ⁽¹⁾	1	Returns 0s
ICEPick control	CONTROL	24 ⁽¹⁾	1	General ICEPick control
Linking mode	LINKING_MODE	24 ⁽¹⁾	1	Specifies how ICEPick manages the TAP selection
Secondary debug TAP register	SDTRj	24 ⁽¹⁾	16	One register exists for each test TAP instantiated. It is used to control selection of each TAP.

⁽¹⁾ Register is 32 bits, but 8 upper bits are used for read/write, block, and register selection. See [Table 27-14](#) pseudo register.

27.2.4.6.2 Register Reset Conditions

Each register bit has a reset condition. One of these reset conditions is used to reset each bit in ICEPick. [Table 27-6](#) shows the reset conditions.

Table 27-6. Register Reset Conditions

Condition	Description
–	The bit always reflects the current value of an input signal.
Fixed	The bit is set to a particular value and does not change during operation.
POR	The bit is reset upon POR.
QTLR	The bit is reset upon state change to Test Logic Reset if the ICEPick TAP is visible and the ICEPick register reset is not blocked. In this sense, reset based on reaching the Test Logic Reset state is qualified.
QnTRST	The bit is reset on assertion low of the device pin nTRST if the ICEPick TAP is visible and the ICEPick register reset is not blocked. In this sense, reset based on nTRST assertion is qualified. Because the assertion of nTRST changes the TAP state to Test Logic Reset, the QTLR reset condition often applies. Unlike QTLR, a bit that is reset based on this condition is not reset if the Test Logic Reset state is reached through changes in TAP state.
ARST	The bit is reset upon any of the above resets. In other words, the bit is reset upon POR or QTLR or QnTRST. In practice, QnTRST is not needed in this equation because nTRST assertion drives the TAP state to Test Logic Reset so the QTLR condition will then apply.

27.2.4.6.3 Register Description

[Table 27-7](#) through [Table 27-13](#) describe the individual registers.

Table 27-7. DSR

Description	The data shift register is the register used to shift bits between the ICEPick TDI and TDO. This register is 32 bits wide. It has multiple shift in points to facilitate shifts on the instruction path and several of the data paths.
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
RESERVED																Instruction shift		BYPASS													
RESERVED																															
RESERVED																Connection shift															

When asked to shift, one bit is shifted from each bit into the next lower bit. A new value is shifted in from TDI while the LSB is shifted out to TDO. The shift register has several insertion points based upon the current TAP state or value in the instruction register.

Table 27-8. IR

Description	The instruction register (IR) contains the current TAP instruction. ICEPick's instruction register is 6 bits wide
Type	W
Reset	IDCODE upon QTLR

5	4	3	2	1	0
INSTRUCTION					

Table 27-9. BP

Description	The bypass register is a 1 bit register. Whatever value is scanned in TDI is preserved and scanned out of TDO one ITCK cycle later.
Type	RW

0
BYPASS

Table 27-10. TAPID

Description	The device identification register allows the manufacturer, part number, and version of a component to be determined through the TAP. The device identification register is scanned in response to the IDCODE instruction. This allows the manufacturer, part number, and variant for the component to be read in a serial binary form.
Type	R

⁽¹⁾ TI internal data**Table 27-13. CONNECT**

Description		The Connect Register serves 2 purposes. First, it is used to guard use of most IR instructions. This prevents noise, hot connecting an emulator cable, or accidental scan by a miss configured scan controller, from causing test, debug, or boundary scan operations from mistakenly engaging debug functions. Secondly, this register can be used to signal that a debugger is connected and that emulation logic should be powered and enabled.													
Type		R (ARST)													
7	6	5	4	3	2	1	0	WRITE		RESERVED		CONNECTKEY

Bits	Field Name	Description	Type	Reset
31:24	TAP_ROUTING	See Table 27-14 .	RW	-
23:18	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	0x0 (ARST)
17	ADVANCERTCKTIMING	When 0, the ICEPick clock voting logic is configured so RTCK lags ITCK. When 1, the ICEPick clock voting logic is configured so RTCK has same timing as ITCK	RW	0 (ARST)
16	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	-
15	UNNATURALSYSRESET	When 0, the system-reset state is consistent with the application controls. When 1, the system-reset state is not consistent with the application controls due to emulation actions or controls.	R	-

Bits	Field Name	Description	Type	Reset
14	REDUCEDTCK	When 0, the ICEPick clock voting logic is configured to operate upto the TCLK input frequency. When 1, the ICEPick clock voting logic is configured to operate upto the TCLK input frequency when no debug TAPs are selected.	RW	0 (ARST)
13	SYSTEMSTATUS	This bit reflects the value of a system status signal.	R	-
12	FREERUNNINGEMUL	This bit drives the FreeRunEmul output port and is used to configure ICECrusher modules for operation with an emulator which has a free running TCLK.	RW	0 (ARST)
11	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R/W	0 (ARST)
10	CLEARALLEXFLAG	When a 1 is written, the latched value of all run bits in all secondary TAPs is cleared back to 0. Writing a 0 has no effect.	W	0 (ARST)
9	GLOBALXEMASK	When 0, the value in the Secondary Debug TAP Register ExecuteAction bit is immediately applied to the secondary TAP and module. When 1, the run signal to the terminal is held at 0. After several secondary TAP's run bit have been set while this bit is 1, changing this bit to 0 will cause all of the secondary TAP to see the run signal at the same time.	RW	0 (ARST)
8	GLOBALRELEASEWIR	When a 1 is written to this bit and the device is held in reset due to the GlobalWaitInReset signal, the GlobalWaitInReset signal is deasserted. This is a self-clearing bit. Writing a 0 has no effect.	R/W	0 (ARST)
7	KEEPOWERINTLR	When 1, the ICEPick logic remains powered at all times. When 0, the ICEPick logic may be powered down in the Test-Logic-Reset state if ICEPick is visible and TMS is 1.	RW	0 (POR)
6	BLOCKSYSRESET	When 1, the device system reset signal is blocked.	RW	0 (ARST)
5	TDOALWAYSOUT	When 1, the device level TDO pin will always be driven (in output mode) regardless of the TAP state. When 0, the device level TDO pin will be influenced by the current TAP state in compliance with the IEEE1149.1 specification (either output or Hi-Z mode)	RW	0 (POR)
4	RESERVED	Reserved, write reset value for further compatibility	W	0 (POR)
3:1	DEVICETYPE	Device Type.	R	011b
0	SYSTEMRESET	Emulator controlled System Reset. This signal provides the scan controller with the ability to assert the system warm reset. When a 1 is written, this behaves as if the external chip warm reset signal had been momentarily asserted. This signal does not reset any emulation logic. This is a self-clearing bit. This is cleared by the assertion of the reset requested. Writing a 0 has no effect.	RW	0 (ARST)

Table 27-19. LINKING_MODE

Description		This register control link features of the ICEPick module																													
Type		RW																													
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TAP_ROUTING								RESERVED				SPONTDISCOFLAG	DESELECTMODE	KEYSEQUENCE								ESERVED	TAPLINKMODE	ActivateMode							
Bits	Field Name	Description	Type	Reset																											
31:24	TAP_ROUTING	See Table 27-14 .	RW	-																											
23:19	RESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	0x0 (ARST)																											

Bits	Field Name	Description	Type	Reset
18	SPONTDISCOFLAG	This flag is set if the TAPs are spontaneously removed from the scan chain or if a selected TAP loses power. It also forces the TDO output to HiZ. Writing a 1 to this bit clears it. Writing a 0 has no effect.	RW	0 (POR)
17:16	DESELECTMODE	See Table 27-20 .	RW	0 (POR)
15:6	KEYSEQUENCE	When the TAPLinkMode is set to "key sequence", this field contains the "key sequence pattern" that will make the ICEPick TAP visible again. 0x2CD is the recommended value. Another 10-bit sequence may be used. During KeySequence detection, LSB of the Key sequence should be shifted into TDI first.	RW	0 (POR)
5:4	ESERVED	Reserved, Read return reset value, write reset value for further compatibility	R	0
3:1	TAPLINKMODE	See Table 27-21 .	RW	0 (POR)
0	ActivateMode	When a 1 is written to this bit, the currently selected TAPLinkMode is activated. ICEPick will link the TAPs according to these settings when the ICEPick TAP is advanced to Run-Test/Idle with any opcode in the IR. When in key-sequence mode, this bit is automatically cleared when the key sequence is detected.	RW	0 (POR)

NOTE: These registers are updated when entering the Update DR state, but the action that results from the update occurs when entering the Run Test/Idle state.

Table 27-20. DESELECTMODE Values

Value	Mode	Behavior
00	Stay-selected	Even though a selected secondary TAP becomes inaccessible, the set of selected TAPs does not change. Scan to any and all modules may not be possible.
01	Reserved	Acts like Stay-Selected
10	Reserved	Acts like Stay-Selected
11	Auto-deselect	When a selected secondary TAP becomes inaccessible due to power constraints, all secondary TAPs are deselected. TDO is forced to Hiz.

Table 27-21. TAPLINKMODE Values

Value	Mode	Behavior
000	Always-first	The ICEPick TAP always exists and is linked as the TAP closest to TDI.
001	Reserved	Reserved (behaves like Always-first)
010	Key-Sequence	When this mode is activated, the ICEPick TAP is no longer visible. The selected secondary TAPs are connected between the device TDI and TDO. Although the ICEPick TAP is not visible, it continues to advance state in step with the other selected TAPs. In this sense it is a shadow TAP. When in the Run Test Idle state, a special address can be scanned that will make the ICEPick TAP visible again.
011	Disappear-forever	Once activated, the ICEPick TAP is no longer visible between the device TDI and TDO. Only a power-on reset will make the TAP visible again.
100	Reserved	Reserved (behaves like Always-first)
101	Reserved	Reserved (behaves like Always-first)
110	Key Sequence with Forwarding	This mode operates in the same manner as the KeySequence mode except that any values shifted in during the Run Test Idle state are driven out the device TDO. The device TDO pin is driven during RunTest Idle.
111	Reserved	Reserved (behaves like Always-first)

27.2.4.6.3.1.2 Debug TAP Linking Control Block

The debug TAP linking block contains the control and status registers used in the selection of secondary TAPs into the master scan path. Up to 16 secondary TAPs can be supported. Each TAP has its own debug TAP control and status register.

Table 27-22 shows the registers available in the ICEPick control block and the value of the TAP_ROUTING_REG[27:24] bit field used to access them.

Table 27-22. Debug TAP Linking Control Block Registers

Register	Register Name	Description
0x0	SDTR0	Secondary debug TAP 0 register
0x1	SDTR1	Secondary debug TAP 1 register
0x2	SDTR2	Secondary debug TAP 2 register
0x3	SDTR3	Secondary debug TAP 3 register
0x4	SDTR4	Secondary debug TAP 4 register
0x5	SDTR5	Secondary debug TAP 5 register
0x6	SDTR6	Secondary debug TAP 6 register
0x7	SDTR7	Secondary debug TAP 7 register
0x8	SDTR8	Secondary debug TAP 8 register
0x9	SDTR9	Secondary debug TAP 9 register
0xA	SDTR10	Secondary debug TAP 10 register
0xB	SDTR11	Secondary debug TAP 11 register
0xC	SDTR12	Secondary debug TAP 12 register
0xD	SDTR13	Secondary debug TAP 13 register
0xE	SDTR14	Secondary debug TAP 14 register
0xF	SDTR15	Secondary debug TAP 15 register

Table 27-23. SDTRj

Description	There is a separate Secondary Debug TAP Register (SDTR) for each secondary TAP (j = 0 to 15).
Type	RW

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bits	Field Name	Description	Type	Reset
31:24	TAP_ROUTING	See Table 27-14.	RW	-
23	BLOCKNTRST	When this bit is 0, the nTRST signal for this secondary TAP follows the device level nTRST. When this bit is 1 and the TAP is deselected, the nTRST signal for this secondary TAP is held high.	RW	0 (ARST)
22	RESERVED	Reserved, read return reset value.	R	0
21	POWERLOSSDETECTED	When this bit is 1, the module associated with this TAP has had its power turned off. Once a power loss has been detected, this bit will remain 1 until manually cleared by writing to this bit. Writing a 1 to this bit clears this latched value back to 0. Writing a 0 has no effect.	R	0 (ARST)

Bits	Field Name	Description	Type	Reset
20	INHIBITSLEEP	When 0, this bit does not influence the clock and the power settings to the module. While this bit is 1, if power or clock for TAP's module is not allowed to be turned off once turned on. The value read does not reflect the value written until the power and clock controller has acted upon a change in the written value.	RW	0 (ARST)
19	TAPPOWER	When 0, the module TAP power is off. When 1, the module TAP power is on.	R	-
18	UNNATURALRESET	When 0, the warm-reset state is consistent with the application controls. When 1, the warm-reset state is not consistent with the application controls due to emulation actions or controls.	R	-
17	INRESETANDRELEASE WIR	Read 1, the module(s) controlled by the secondary TAP is in the reset state. Read 0, the module(s) is not in reset. When a 1 is written to this bit and the module is held in reset due to the WaitInReset bit, the module reset is released. This only occurs if WaitInReset is 1 and it is the only cause for holding the module in reset. This is a self-clearing bit. Writing a 0 has no effect.	RW	0 (ARST)
16:14	RESETCONTROL	Override the application controls of the functional warm reset to a module. See Table 27-24 .	RW	0 (ARST)
13	DEBUGENABLE	When 1, the module(s) associated with this secondary TAP has its debug logic enabled. This is referred to as debug enable or connect on some modules. When 0, the debug logic is allowed to be turned off.	RW	0 (ARST)
12:11	DEBUGMODE	Specify the debug mode of the module upon power-on-reset. See Table 27-25 .	RW	0 (ARST)
10	DEBUGANDEXECUTE	Read 0, all processors (modules) on this secondary TAP are in execution state. Read 1, one or more processors (modules) on this secondary TAP have entered a state where debugger interaction is required. Writing a 1 enables the module to take action on a preloaded execution command, such as run. This bit may be gated by the GlobalExecuteMask. Writing a 0 has no effect.	RW	0 (ARST)
9	VISIBLETAP	When 1, the TAP is currently selected and visible in the active scan chain.	R	-
8	SELECTTAP	While 1, the TAP is selected for inclusion in the master scan path. While 0, the TAP is not selected. The effects of changing this bit do not take place until the Run-Test-Idle state is reached.	RW	0 (ARST)
7	POWERDOWNDESIRED	When 0, the module's power is not being affected by the by emulation controls or actions. When 1, the power would normally be turned off to the module if it were not for emulation controls.	R	-
6	FORCEPOWER	When 0, this bit does not influence the module power state. When 1, the TAP and its module are held in a operational powered state regardless of whether the TAP is selected or not. The value read does not reflect the value written until the power controller has acted upon a change in the written value.	W	0
5	POWER	When 0, the module power is off. When 1, the module power is on.	R	-
4	CLOCKDOWNDESIRED	When 0, the module clock state is not being affected by emulation controls or actions. When 1, the clock would normally be turned off to the module if it were not for emulation controls.	R	-

Bits	Field Name	Description	Type	Reset
3	FORCEACTIVE	When 0, this bit does not influence the module's power or clock settings. When 1, the clock for TAP's module is forced on. It is implied that this control will also turn on the power. The value read does not reflect the value written until the power and clock controller has acted upon a change in the written value.	W	-
2	CLOCK	When 0, the module clock is off (Idle). When 1, the module clock is on.	R	-
1	TAPACCESSIBLE	When 0, the TAP cannot be accessed. When 1, the TAP can be accessed.	R	-
0	TAPPRESENT	When 0, there is not a TAP assigned to this spot. When 1, this TAP exists in the device.	R	-

Table 27-24. RESETCONTROL Values

Value	Command	Description
000	Normal Operation	Reset operates under the normal control of the application or device controls.
001	Wait-in-reset (extended reset)	The module(s) controlled by this secondary TAP will remain in the reset state once the reset is asserted. This bit alone does not reset the processor.
010	Block Reset	Warm-reset to the module is blocked. At this point, only emulation reset controls will work.
011	Block and Assert Reset	Assert and hold the reset to the module.
1xx	Cancel	Cancels reset command lockout

Table 27-25. DEBUGMODE Values

Value	Debug Mode	Description
00	Default mode	The processor will use whatever debug mode is its default mode.
01	Monitor mode	The debug features of the processor will be configured for monitor mode.
10	Halt mode	The debug feature of the processor will be configured for halt or stop mode.
11	Real-time halt mode	The debug features of the processor will be configured for real-time halt mode.

27.2.5 ICEPick Basic Programming Model

27.2.5.1 Basic Initialization

The following sequence connects the ICEPick to the debugger and configures ICEPick rtck behavior:

1. Connect ICEPick:
 - Select IR scan.
 - Send the CONNECT instruction in IR scan (000111).
 - Select DR scan.
 - Send the following value in DR scan 10001001 (write and connect key).
 - At the update DR, the ICEPick is in connected state.
2. Configure ICEPick:
 - Select IR scan.
 - Send the the ROUTER instruction in IR scan (000010).
 - Select DR scan.
 - Send the following value in DR scan (see [Table 27-18](#)):
 - WRITE (bit 32) = 1
 - BLOCK (bit field [31:28]) = 0x0, block 0 is ICEPick control.
 - REGISTER (bit field [27:24]) = 0x0
 - ADVANCERTCKTIMING (bit 17) must be configured.

- FREERUNNINGEMUL (bit 12) must be configured.
- Configure other bit field if needed.
- At the update DR, the ICEPick is properly configured.

27.2.5.2 Adding a TAP in the Debug Chain

The following sequence adds a new TAP in the debug chain:

1. Select IR scan.
2. Send the ROUTER instruction in IR scan (000010).
3. Select DR scan.
4. Send the following value in DR scan (see [Table 27-18](#)) to enable power and clock for the TAP:
 - WRITE (bit 32) = 1
 - BLOCK (bit field [31:28]) = 0x2; bloc 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number, select the TAP to be added to the chain; see [Table 27-2](#) for more information.
 - FORCEACTIVE (bit 3) = 1, enable the TAP power and clock.
 - FORCEPOWER (bit 6) = 1, force the TAP power to ON state regardless of whether the TAP is selected or not.
 - INHIBITSLEEP (bit 20) = 1, force the TAP clock to be active.
5. Read back the value in next DR scan:
 - WRITE (bit 32) = 0
 - BLOCK (bit field [31:28]) = 0x2; block 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number , select the TAP to be added to the chain; see [Table 27-2](#) for more information.
6. Check if the FORCEACTIVE, FORCEPOWER, and INHIBITSLEEP bits are set to 1.
7. Send the following value in DR scan (see [Table 27-18](#)) to enable debug mode:
 - WRITE (bit 32) = 1
 - BLOCK (bit field [31:28]) = 0x2; block 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number , select the TAP to be added to the chain; see [Table 27-2](#) for more information.
 - DEBUGENABLE (bit 13) = 1; enable the TAP debug.
 - DEBUGMODE (bit field [12:11]) = MODE; see [Table 27-25](#) for available debug modes.
8. Read back the value in next DR scan:
 - WRITE (bit 32) = 0
 - BLOCK (bit field [31:28]) = 0x2; block 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number , select the TAP to be added to the chain; see [Table 27-2](#) for more information.
9. Check if DEBUGENABLE and DEBUGMODE bit are well set.
10. Send the following value in DR scan (see [Table 27-18](#)) to add the TAP in the chain:
 - WRITE (bit 32) = 1
 - BLOCK (bit field [31:28]) = 0x2; block 2 is Debug TAP Linking Control.
 - REGISTER (bit field [27:24]) = TAP number , select the TAP to be added to the chain; see [Table 27-2](#) for more information.
 - SELECTTAP (bit 8) = 1; add the TAP in the chain.
11. Go in Run Test Idle (RTI) so the change takes effect and the TAP is added to the chain (a wait may be needed).

When the TAP is added to the chain, DR and IR are longer (ICEPick length + new TAP).

To write in IR for the new TAP, write BYPASS in ICEPick IR so the next DR is not taken into account and is only 1 bit for ICEPick.

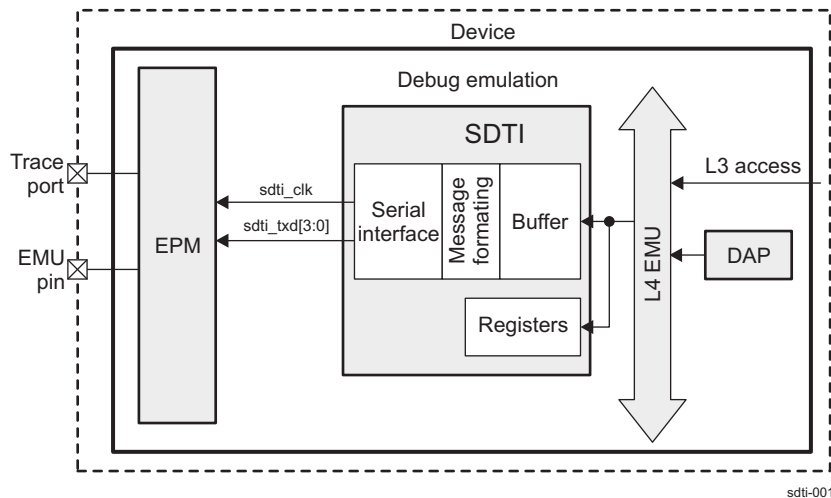

27.3 SDTI Module

This section describes the SDTI in the device.

27.3.1 SDTI Overview

SDTI is a main component that implements system trace in the device. The SDTI is connected to the L4_EMU and mapped to the EMU domain. L4_EMU is accessible by the MPU and the digital signal processor (DSP). [Figure 27-8](#) shows the SDTI in the device.

Figure 27-8. SDTI in the Device

The SDTI provides real-time software tracing to device. It generates software messages, which are encoded as defined in the custom protocol.

NOTE: The custom protocol is not MIPI® compliant.

Messages are a way for software to export crucial information and thus provide a high level of visibility on system behavior (task entry, procedures calls, system status, test signatures, and memory allocation); 256 message channels, which can be allocated between software components, are available.

Messages are exported to trace receivers through a serial interface.

SDTI has its own local, dedicated first in first out (FIFO) buffering to allow trace capabilities concurrent to ETM trace captured in ETB.

SDTI implements only trace export from device to remote PC through an emulator box. There is no receive path feature in the SDTI. A standard asynchronous serial port (UART, 8 data bits, 1 stop-bit, no parity) can be used as a back-channel to send emulation related control requests and data back to device.

27.3.2 SDTI Environment

The trace interface has four trace data pins and one trace clock, as shown in [Table 27-26](#).

Table 27-26. SDTI Pins

Port	Width	I/O ⁽¹⁾	Reset Value	Description
sdti_clk	1	O	1	Trace interface clock output
sdti_txd	4	O	0000	Trace interface data

⁽¹⁾ I = Input; O = Output

NOTE: 1, 2, and 4-bit serial interface configurations are supported.

Serial interface is a dual-edge interface (new sdti_txd data is available with rising and falling edge of sdti_clk). Interface can be also configured in single-edge mode where data are available with the falling edge of sdti_clk. This can be configured in the [SDTI_SCONFIG\[4\] SINGLEEDGE](#) bit

Serial interface operates in clock stop regime (the serial clock is not free-running), when there is no trace data there is no trace clock.

27.3.2.1 SDTI Pins Configuration Mode

Figure 27-9 through Figure 27-11 show the SDTI connected with an emulator box in four, two, and one data pin configuration, respectively. The number of pins used for transmission can be configured in the [SDTI_SCONFIG\[6:5\] TXDSIZE](#) bit field.

Figure 27-9. SDTI Connected in Four Data Pins Mode

Figure 27-10. SDTI Connected in Two Data Pins Mode

Figure 27-11. SDTI Connected in One Data Pin Mode

27.3.2.2 SDTI Protocol

The SDTI serial interface is a dual-edge, 4-pin serial interface used to connect the device to trace receivers (for example, XDS560T).

Trace receivers sample trace data on each clock edge. The trace clock (SDTI_CLK) starts with a falling edge. The sdti_clk signal is forced high until the first data value is available.

Serial interface operates in clock stop mode; when there is no data available, the clock stops. SDTI_CLK is not a free-running clock.

To support older trace receivers, serial interface can be placed into single-edge mode where data is captured with the falling edge of the trace clock ([SDTI_SCONFIG\[4\]](#) SINGLEEDGE = 1).

[Figure 27-12](#) shows the SDTI dual-edge serial interface waveform.

[Figure 27-13](#) shows the SDTI single-edge serial interface waveform.

The SDTI serial interface is configurable to support one, two, and four data bits operation. Depending on the configuration, trace data is exported on sdti_txd[0], sdti_txd[1:0], or sdti_txd[3:0].

Serial clock frequency is selected in the SDTI serial configuration register (the [SDTI_SCONFIG\[3:0\]](#) SDTISCLKRATE bit field). Programmers must select the correct serial frequency (choose division factor) based on the functional clock frequency.

27.3.2.3 SDTI Data Format

[Table 27-27](#) summarizes the message types.

Table 27-27. SDTI CPU Software Messages

Type	Identification
CPU1 timestamped message	001D DAtt
CPU1 message	010D DA00
CPU2 timestamped message	011D DAtt
CPU2 message	110D DA00

NOTE:

- DD: Data length
 - 00 = 8-bit data
 - 01 = 16-bit data
 - 10 = 32-bit data
 - 11 = Reserved
- A: Address length
 - 0 = No address
 - 1 = 8-bit address
- tt: Time stamp bits always zero in SDTI

Table 27-28 to Table 27-31 show detailed message structure.

Table 27-28. CPU1 Timestamped Message

Description	Format		
Header	001D DA00		
Timestamp	0		
Address	A = 1	A = 0	
	Ad[7:0]	Nonexistent field	
Data	DD = 00	DD = 01	DD = 10
	Da[7:0]	Da[15:8]	Da[31:24]
			Da[23:16]
		Da[7:0]	Da[15:8]
		Da[7:0]	

Table 27-29. CPU1 Message

Description	Format		
Header	010D DA00		
Address	A = 1	A = 0	
	Ad[7:0]	Nonexistent field	
Data	DD = 00	DD = 01	DD = 10
	Da[7:0]	Da[15:8]	Da[31:24]
			Da[23:16]

		Da[15:8]	Da[7:0]	

27.3.3 SDTI Integration

Figure 27-14 shows the internal connections between the SDTI and other modules in the device.

Figure 27-14. SDTI Integration

27.3.3.1 Clocking and Reset

27.3.3.1.1 Clocks

The SDTI receives two clocks:

- SDTI_ICLK: The L4_EMU clock for the interface and the functional clock for SDTI
- SDTI_FCLK: The serial interface base clock, which is always twice as fast as SDTI_ICLK

Trace serial interface (sdti_clk) runs on a clock generated in SDTI. The serial interface clock is derived from SDTI_FCLK in programmable clock divider.

Divider factors for serial clock generation are referenced to SDTI_ICLK. These factors range from 1 to 10. SDTI_FCLK always has an internal clock that runs twice as fast as the serial clock selected through division factors, which is used as a base clock in dual-edge serial transmitters.

27.3.3.1.2 Reset

The SDTI is reset with hardware POR. All SDTI registers are asynchronously reset. The SDTI remains operational and with its setup preserved when a warm reset is triggered to export the trace history to the trace controller. This trace history may contain key information from a debug perspective for understanding the root cause of the warm reset.

The PRCM module delivers the EMU_RSTPWON reset qualifier and the RESET signal to distinguish power on from a warm (soft) reset.

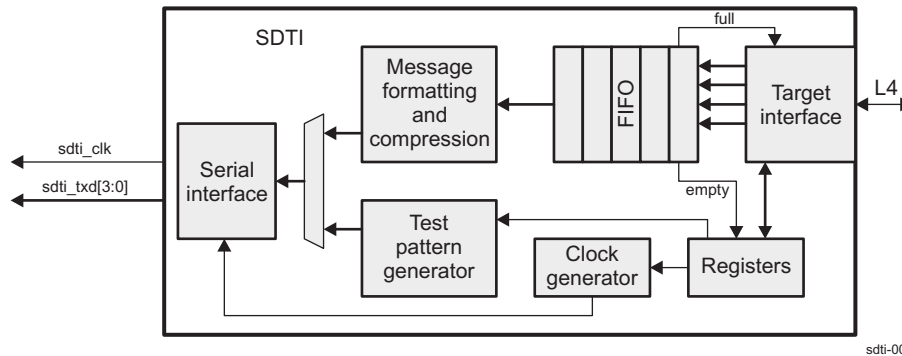

The application or debugger software can reset the SDTI at any time by writing 1 to the [SDTI_SYSCONFIG\[1\] SOFTRESET](#) bit. This puts the SDTI in the same reset state as a hardware reset.

27.3.4 SDTI Functional Description

27.3.4.1 SDTI Block Diagram

Figure 27-15 is a block diagram of the SDTI.

Figure 27-15. SDTI Block Diagram

sdti-008

The SDTI is configured through the L4 EMU target interface.

All SDTI registers are 32-bit (double word) aligned. For information about handling non-aligned addresses, supported/not supported byte enables, access to nonexistent memory address, reads to write-only registers, and writes to read-only registers, see [Section 27.3.4.9, SDTI Error Handling](#).

The SDTI is active (enabled) when enabled through claim procedure. For information about the claim procedure, see [Section 27.3.4.2, SDTI Ownership](#). When enabled, SDTI generates messages or test patterns and exports them through the serial interface.

27.3.4.2 SDTI Ownership

Some SDTI resources can be owned by the application or by the debugger. Ownership is required to configure or program the SDTI. Ownership determines whether write access is granted to the SDTI configuration registers. SDTI resource ownership is exclusive. Hence, simultaneous use of SDTI resources by both debugger and application is not permitted. However, the debugger can forcibly seize ownership of SDTI resources.

NOTE: Read access does not require ownership; therefore, either party can read any SDTI register with or without ownership.

The application and the debugger cannot simultaneously write to the following SDTI resources (also called units):

Window control register (accompanied by the serial configuration register and the test control register)

27.3.4.2.1 Ownership States

Ownership has three basic states:

- Available: The unit has not been claimed.
- Claimed: The unit has been claimed.
- Enabled: The unit is enabled by the owning party.

27.3.4.2.1.1 Available State

The SDTI is set to available state when one of two conditions occurs:

- The state is available when POR is asserted.
- The state is available if the SDTI is owned by the debugger and the emulator is disconnected.

NOTE: A warm reset has no effect on the operation of the SDTI. An emulator disconnect has no effect when the application owns the unit.

27.3.4.2.1.2 Claimed State

The SDTI is in claimed state when the debugger or the application claims it. The claimed state provides exclusive access to the owner. The other party is not permitted write access to the unit until the owning party releases the claim. Once a unit has been claimed, only the owner can write to the other resources controlled by the claim.

The debugger, however, is allowed to forcibly seize control of a unit, if already claimed by the application, by setting the [SDTI_WINCTRL\[29\]](#) DEBUGGEROVERRIDE bit.

27.3.4.2.1.3 Enabled State

The SDTI enters into enabled state when it is activated. The owner can continue to write to other resources while the SDTI is enabled.

27.3.4.2.2 Ownership Commands

Ownership of SDTI resources is managed through the [SDTI_WINCTRL\[31:30\]](#) OWNERSHIP bit field. [Table 27-32](#) lists the ownership commands.

Table 27-32. Ownership Commands

Command	Meaning	Description
00	Release ownership	Release ownership of SDTI. The release command is accepted only from the owner.
01	Claim ownership	Claim access to the SDTI. The claim command is successful only if the unit is available or the requester is the debugger and the SDTI_WINCTRL[29] DEBUGGEROVERRIDE bit is high.
10	Enable unit	Activate the SDTI for use. The enable command is accepted only from the owner.
11	No operation	The NOP command does not affect ownership or claim state.

27.3.4.2.3 Claim Bits

The 4 claim bits are implemented in the [SDTI_WINCTRL](#) register, as shown in [Table 27-33](#).

Table 27-33. Claim Bits

Field	Width	R/W	Reset	Description
Ownership[1:0]	2	R	00	Read to get current ownership status. The claim status encoding is (0 = available; 1 = claimed; 2 = enabled; 3 = reserved)
		W		Send command to modify ownership state. See Table 27-32 . ⁽¹⁾
DebuggerOverride	1	R	1	A read from the DEBUGGEROVERRIDE bit returns 1.
		W		This qualifier bit is used with the debugger claim request. The DEBUGGEROVERRIDE bit is not registered. When written with DEBUGGEROVERRIDE set to 1, a claim request by the debugger is granted, regardless of the ownership status of the unit. When written with DEBUGGEROVERRIDE set to 0, the claim request is granted only if the unit is available.
CurrentOwner	1	R	0	This value reflects the SDTI ownership when the register is in a nonavailable state. 0 = Debugger owns resource. 1 = Application owns resource.

⁽¹⁾ A successful command causes these bit values to reflect the new state.

27.3.4.2.4 Claim Resets

When the SDTI is owned by the debugger, the resource is released if the debugger is disconnected.

If the SDTI is owned by the application and the processor enters debug state, the resource continues to belong to the application. The SDTI is not sensitive to debug state.

If the SDTI ownership is released while data are in the SDTI FIFO, the serial interface continues to export data until the FIFO is drained.

27.3.4.3 Trace Data Collection

The messages allow the application software to export, through the serial trace interface, key information that provides high-level visibility on system behavior (task entry, system status, test signature, and memory allocation); 256 message channels are available, starting at 0x5460 0000.

To minimize cycle overhead, the generation of messages is implemented through a dedicated address window. Each write to an address within the window triggers a message.

To facilitate memory management unit (MMU) use for channel enabling and disabling, channel to memory address mapping is organized as follows:

- Each of the 256 channels is allocated 4KB of memory. This corresponds to an MMU page.
- Within 4KB, CPU1 and CPU2 channels are interleaved:
 - 1KB CPU1 message
 - 1KB CPU1 timestamped message
 - 1KB CPU2 message
 - 1KB CPU2 timestamped message
- Each write to addresses within the first KB of channel space triggers a CPU1 message.
- Each write to addresses within the second KB of channel space triggers a CPU1 timestamped message.
- Each write to addresses within third KB of channel space triggers a CPU2 message.
- Each write to addresses within fourth KB of channel space triggers a CPU2 timestamped message.

When there is a write in that range, SDTI hardware decodes the access and stores the address decoded as channel, CPU1/2, and message/ timestamped message, along with the data and access size.

The message header is determined from the accessed address and access type (1, 2, or 4 bytes).

Trace matching for CPU1 and CPU2 message generation can be globally enabled or disabled in the [SDTI_WINCTRL](#) register.

Although timestamped messages are supported, the SDTI does not implement time-stamping logic, and all time-stamp-related bit fields in timestamped message are always zeroed.

Timestamped messages can be used as an end message marker. Trace software generates a timestamped message on the same channel with previously exported non-timestamped messages as an end message marker.

There is no MConn-ID supported on L4_EMU and thus no capability to differentiate accesses from various initiators. Each access to the CPU1 address space generates a CPU1 message/ timestamped message, regardless of the initiator. The same applies for CPU2 message generation.

Debugger accesses are differentiated from other initiators by using the MRegDebug qualifier. If enabled through the [SDTI_WINCTRL\[2\]](#) DEBUGGERTRACEEN bit, debugger accesses to the trace matching window generate a CPU1 or CPU2 message, depending only on the address accessed. The external trace receiver cannot differentiate between debugger-initiated and application-initiated trace. Otherwise, debugger writes to the trace matching address window do not generate messages.

Burst writes not supported by L4_EMU burst from level 3 (L3) are split into single writes in the L3/L4_EMU bridge (for example, originating from STM instruction), with each of them triggering a separate message.

As a simple compression scheme for serial bandwidth improvement, in case of consecutive writes to the same message channel, the channel address is omitted from a message. For particular message encoding, see [Section 27.3.2.3, SDTI Data Format](#). Because initiators are not differentiated on L4_EMU compression, the scheme is based only on the address accessed. Consecutive accesses to the same address originating from various initiators activates compression.

The SDTI does not lose messages. If it is necessary, the SDTI stalls its interface until there is enough space in the FIFO to store new messages.

A valid write access to the trace address matching window with an all-zeroes byte-enable pattern do not trigger a message.

The SDTI starts to output serial data as soon as it has at least one captured line in the FIFO.

27.3.4.4 Trace Buffer FIFO

The SDTI FIFO is organized as listed in [Table 27-34](#).

Table 27-34. FIFO Data Organization

Field	Size (Bits)
Timestamped message (end message marker)	1
CPU1/CPU2	1
Channel number	8
Data size (in bytes)	2
Data	32

When full, the SDTI FIFO stalls L4_EMU by not acknowledging the write access. When FIFO room becomes available, the SDTI can capture a new message.

The SDTI FIFO status can be polled by reading the [SDTI_SYSSTATUS\[8\] FIFOEMPTY](#) bit. FIFOEMPTY reflects the state of SDTI buffering, including the SDTI FIFO and serial interface shift register. When read as 1, there is no more data in the SDTI to be exported.

Check the SDTI FIFO status before powering down the EMU domain or changing the serial interface configuration.

27.3.4.5 Serial Interface Test Pattern Generation

To support calibration, tuning, and testing, the SDTI includes a test pattern generator, which drives the serial interface when testing mode is selected.

When serial interface test mode is selected and the SDTI is enabled, the SDTI continuously exports test patterns until it is disabled. For the test mode enable procedure, see [Section 27.3.5.2, Serial Interface Test Mode Setup](#).

[Table 27-35](#) lists the different patterns that are supported.

Table 27-35. Test Pattern Format

Pattern Name	Pattern Example
Simple A	0x5, 0xA
Simple F	0x0, 0xF
Walking ones	0x0, 0x1, 0x2, 0x4, 0x8
Ramp (incremental counter)	0x0, 0x1, 0x2,..., 0xF, 0x0,...
Pseudo random (LFSR)	-

Test patterns are exported in chunks that are sized to the internal serial interface data bus. For example, if the serial interface is configured as 4-wire, test patterns are exported in a multiple of four patterns. For 2-wire interface, patterns are exported in a multiple of 8 patterns; for 1-wire interface, patterns are exported in a multiple of 16 patterns.

27.3.4.5.1 Simple Patterns

Simple A and F patterns can be used for calibration, observing cross-talk, and ground bounce.

These patterns depend on the interface width selected. [Table 27-36](#) summarizes the patterns generated.

Table 27-36. Simple Test Pattern

Interface Width (Bits)	Pattern A	Pattern F
1	0, 1	0, 1
2	01, 10	00, 11
4	0x5, 0xA	0x0, 0xF

27.3.4.5.2 Walking Ones

The walking-ones pattern can be used to verify connectivity and correct bits that are being driven.

This pattern depends on the interface width selected. [Table 27-37](#) lists the patterns generated.

Table 27-37. Walking Test Pattern

Interface Width (Bits)	Pattern
1	0, 1
2	00, 01, 10
4	0x0, 0x1, 0x2, 0x4, 0x8

27.3.4.5.3 Ramp Pattern

The ramp pattern can be used to verify that no data is lost at the trace receiver.

The ramp pattern generator is implemented as a 4-bit up counter.

27.3.4.5.4 Pseudo Random (LFSR) Pattern

The linear feedback shift register (LFSR) pattern can be used to verify the transporting of SDTI data across the entire software stack without loss of data.

Pseudo random data is obtained from the 16-bit LFSR. The shift register implements the following polynomial:

$$G(x) = x^{16} + x^{15} + x^{13} + x^4 + 1$$

LFSR is initialized with a 0xFFFF each time pattern generation is enabled.

This LFSR can provide a 64-K long unique data sequence of 16-bit data. For the LFSR pattern, the LSBs are output (the lower 4 bits are output in the case of a 4-bit interface). The upper bits keep the pattern unique for 64-K samples.

The first six values of LFSR are:

1. 0xFFFF
2. 0x5FEF
3. 0xBFDE
4. 0xDFAD
5. 0x1F4B
6. 0x3E96

27.3.4.6 CoreSight Integration Mode

As a CoreSight-compliant peripheral, the SDTI provides an integration mode where the interface input ports can be probed and the output ports can be driven. The following CoreSight integration registers are used to set up and use this mode:

- [INT_MODE_CTRL_REG](#)
- [INT_OUTPUT_REG](#)
- [INT_INPUT_REG](#)

The [CLAIM_TAG_SET_REG](#) register is included for CoreSight compliance. Normally, the lower 4 bits are used for claiming and releasing debug components. The SDTI, however, implements a more sophisticated claim mechanism. These bits can be used as software semaphores to help manage the debug resources, although the claim-and-enable mechanism of the SDTI resources must still be used. Writing 1 to one of the set bits causes the corresponding bit in the claim tag value word to go high.

The [CLAIM_TAG_CLEAR_REG](#) bits can be used as software semaphores to help manage the debug resources. Writing 1 to one of the CLEAR bits causes the corresponding bit in the claim tag value word to go low. Reading this register returns the value of the claim tag.

27.3.4.7 Serial Interface Clock Generation

The `sdti_clk` is derived from `SDTI_FCLK` with a programmable clock divider controlled by the [SDTI_SCONFIG\[3:0\]](#) `SDTISCLKRATE` bit field. [Table 27-38](#) shows the divider for the value of the [SDTI_SCONFIG\[3:0\]](#) `SDTISCLKRATE` bit field.

Table 27-38. sdti_clk Divider Value

SDTISCLKRATE Value	Division Value
0x0	Division by 1
0x1	Division by 1
0x2	Division by 2
0x3	Division by 3
0x4	Division by 4
0x5	Division by 5
0x6	Division by 6
0x7	Division by 7
0x8	Division by 8
0x9	Division by 9
0xA	Division by 10
Others	Division by 1

27.3.4.8 SDTI Memory Mapping

[Table 27-39](#) shows the SDTI memory mapping, and [Table 27-40](#) provides channel address examples.

Table 27-39. SDTI Memory Mapping

CPU2 message	51	0x33800 – 0x33BFF
CPU2 timestamped message	255	0xFFC00 – 0xFFFFF

27.3.4.9 SDTI Error Handling

The SDTI port returns the in-band error as a response in the following cases:

- Unsupported master command
- Unsupported byte enable
- Unaligned address
- Application write access to locked SDTI registers

Read and write accesses pointing to memory holes are considered as software errors, not interconnect errors. Such accesses get a valid response, do not affect the module behavior, and are not reported. In case of a read command, the returned data is zeroes.

A read from the trace matching address window is also considered a software error and returns a valid response with don't care data (all zeroes).

A write access to the trace matching window with CPU1 or CPU2 message generation disabled returns a valid response.

Read accesses are not affected by the state of the lock access register.

Debugger write accesses are never locked (affected by the state of the [LOCK_ACCESS_REG](#) register).

27.3.5 SDTI Basic Programming Model

27.3.5.1 Trace Setup

To enable trace, perform the following steps:

1. If setup is performed through application software, enable write access to the SDTI by writing unlock key to the lock access register ([LOCK_ACCESS_REG](#)).
2. Claim the SDTI through the ownership procedure.
3. Configure the serial interface.
4. Configure [SDTI_WINCTRL](#) to enable message generation.
5. Enable the SDTI through the ownership procedure.

Interface configuration (data width, serial clock selection, dual-/single-edge of operation) must be considered as static and are not to be changed on the fly. The serial interface must be properly configured before enabling trace capture and the interface configuration must not be changed while data are in the SDTI FIFO.

If the address window is disabled (CPU1 and CPU2 message generation is disabled in the [SDTI_WINCTRL](#) register while data are in the SDTI FIFO), the serial interface continues to export data until the FIFO is drained.

Write access to the disabled address window has no effect.

If SDTI ownership is released while data are in the SDTI FIFO, the serial interface continues to export data until the FIFO is drained.

If released (in AVAILABLE ownership state), the SDTI does not generate new messages.

If one trace session ends and a new session starts without a change in the interface configuration, the programming model is:

1. Disable trace.
2. Wait until SDTI FIFO is drained.
3. Enable trace and thus start a new session.

This ensures that the first message in the new session is always exported with the address field.

In case of a short disable/enable sequence (when trace is re-enabled while data from a previous session are still in the SDTI FIFO), session breaks are filtered out (disregarded). From an address compression standpoint, when compression is on, the message address field in the new session depends on the previous trace session.

Functional or message generation mode has priority over serial interface test mode (if message generation and test mode are enabled, the SDTI is in functional mode).

27.3.5.2 Serial Interface Test Mode Setup

To enable serial interface test mode, perform the following steps:

1. If setup is performed through application software, enable write access to the SDTI by writing unlock key to the lock access register ([LOCK_ACCESS_REG](#)).
2. Claim the SDTI through the ownership procedure.
3. Configure the serial interface.
4. Configure [SDTI_WINCTRL](#) to disable message generation.
5. Configure [SDTI_TESTCTRL](#) to select test pattern and test pattern generation mode.
6. Enable the SDTI through the ownership procedure.

The SDTI continues to export test patterns until one of the following occurs:

- Serial test mode is disabled.
- Message generation is enabled.
- The SDTI is released.

CAUTION

Serial interface test mode must be entered only when trace is not enabled and the SDTI FIFO is empty. Switching to serial interface test mode while trace is active leads to unpredictable results.

27.3.5.3 CoreSight Integration Mode Setup

To enable the serial CoreSight integration mode, perform the following steps:

1. If setup is performed through application software, enable write access to the SDTI by writing unlock key to the lock access register ([LOCK_ACCESS_REG](#))
2. Switch to integration mode by setting the [INT_MODE_CTRL_REG](#)[0] ITM bit to 1.
3. The SDTI remains in Integration mode until [INT_MODE_CTRL_REG](#)[0] ITM is cleared to 0.

CAUTION

Integration mode must be entered only when trace is not enabled and the SDTI FIFO is empty. Switching to integration mode while trace is active leads to unpredictable results.

27.3.5.4 SDTI Register Ownership

[Table 27-41](#) lists all the SDTI registers with their ownership and description.

Table 27-41. SDTI Register Ownership

Address Offset	Mnemonic	Description	R/W	Ownership
0x000	SDTI_REVISION	SDTI identification register	R	No ownership
0x010	SDTI_SYSCONFIG	SDTI system configuration register	R/W	No ownership

Table 27-62. CLAIM_TAG_SET_REG

Address Offset	0x0000 0FA0		
Physical Address	See Table 27-43	Instance	SDTI
Description	The Claim Tag Set register is included for CoreSight compliance. Normally the lower 4 bits are used for claiming and releasing debug components, but SDTI implements a more sophisticated Claim mechanism. These bits can be used for software semaphores to help manage the debug resources, although the claim and enable mechanism of the SDTI resources must still be used. Writing a 1 to one of the set bits will cause the corresponding bit in the Claim Tag Value word to go high.		
Type	RW		

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

27.4 Emulation Pin Manager

This section describes the debug pins in the device.

27.4.1 EPM Overview

The EPM manages the multiplexing of the emulation pin to the application pin manager. [Figure 27-16](#) shows the EPM in the device.

Figure 27-16. EPM Overview

For more informations about the application pin manager, see [Chapter 13, System Control Module](#).

27.4.2 EPM Integration

The EPM is in the EMU power domain and is connected to the L4 debug interconnect for register control access.

27.4.3 EPM Functional Description

27.4.3.1 EPM Overview

Some subsystems provide a debug port that can be configured to support a specific debug and trace feature. The configuration and debug source selection are done through the EPM.

At the device level, the platform shares a unique debug port. A similar mechanism allows configuring and selecting a specific debug source for each pin. This allows supporting concurrent debug features, provided that pin mapping does not conflict.

The device EPM can be programmed from the application or debugger software. A claim mechanism ensures exclusive ownership. However, the debugger can override the ownership state.

The debug port is mapped on top of a set of application pins. The device platforms provide the application software with the flexibility to map a set of peripheral interfaces to these pins. The configuration and the application source selection are done through the device application pin manager in the system control module (SCM) (for more information, see [Chapter 13, System Control Module](#)).

When the EPM is programmed to map a debug function to the debug port, the application pin manager (in the SCM) automatically selects the EPM channel.

27.4.3.2 EPM Multiplexing

EPM multiplexes multiple debug signals to the `etk_xxx` and `jtag_emu0/1` signals. The multiplexing function is controlled by the following registers:

- [DAPC_EPM0](#)
- [DAPC_EPM1](#)
- [DAPC_EPM2](#)

Multiple signals can be controlled by a single bit field (for example, the etk_d10, etk_d9, and etk_d8 signals are controlled by the [DAPC_EPM1\[19:16\]](#) DBGP12 bit field).

[Table 27-100](#) lists the different modes supported for each pin and the bit field that controls the output mode.

Table 27-100. EPM Multiplexing

Debug Control	Interface Signals	ETM 16		ETM 8		IVA HS-RTDX/Triggers 2-Pin Mode		SDTI 4 Data		SDTI 4 Data		SDTI 2 Data		SDTI 1 Data	
		Function	Dir	Function	Dir	Function	Dir	Function	Dir	Function	Dir	Function	Dir	Function	Dir

	etk_d3	etk_d3	O	etk_d3	O		–		–		–		–		–
	etk_d2	etk_d2	O	etk_d2	O		–		–		–		–		–
	etk_d1	etk_d1	O	etk_d1	O		–		–		–		–		–
	etk_d0	etk_d0	O	etk_d0	O		–		–		–		–		–
	etk_ctl	etk_ctl	O	etk_ctl	O		–		–		–		–		–
etk_clk	etk_clk	O	etk_clk	O		–		–		–		–		–	
DBGP1	jtag_emu1				–	emu1	IO		O	sdti_txd0 ⁽³⁾	O	sdti_txd1 ⁽³⁾	O	sdti_txd0 ⁽³⁾	O
DBGP0	jtag_emu0				–	emu0	IO		O	sdti_clk ⁽¹⁾	O	sdti_txd0 ⁽¹⁾	O	sdti_clk ⁽¹⁾	O

⁽¹⁾ Two SDTI pins can be mapped to the same etk_#; SDTI_CLK selects the sdti_clk pin, and SDTI_DATA selects the sdti_txd# data pin.

⁽²⁾ To map the uart1_rx pin, configuration must be done on the application pin manager (that is, SCM)

⁽³⁾ Two SDTI data share the same etk_#; sdti_txd0 is mapped on jtag_emu1 if sdti_clk is mapped on jtag_emu0; and sdti_txd1 is mapped on jtag_emu1 if sdti_txd0 is mapped on jtag_emu0.

All the output pins are controlled by a 4-bit bit field that configures the current mode. [Table 27-101](#) shows the list of modes supported and the corresponding values to enter in the EPM control bit field in the following registers:

- [DAPC_EPM0](#)
- [DAPC_EPM1](#)
- [DAPC_EPM2](#)

Table 27-101. EPM Control

EPM Control Value	Debug Mode	Subsystem	
0000	Boot mode – Default state at POR		
0001	Trigger	ICEPick	
0010	HS-RTDX	IVA	
0011	Reserved	Reserved	
0100	Trace	ETM	MPU
0101	Trace	Reserved	
0110

27.4.3.3 Concurrent Debug Support

Table 27-102 summarizes the concurrent debug scenarios supported in the device.

Table 27-102. Concurrent Debug Interfaces

	ETM16	ETM8	Triggers	IVA	SDTI	SDTI
				HS-RTDX		
⁽¹⁾⁽²⁾ ETM16			x	x	x	
ETM8			x	x	x	x
Triggers	x	x		x ⁽¹⁾		x
IVA HS-RTDX	x	x	x ⁽¹⁾			x
SDTI ⁽³⁾	x	x				
SDTI ⁽²⁾		x	x	x		

⁽¹⁾ Single HS-RTDX data line concurrent with single trigger

⁽²⁾ 4-pin trace data plus trace clock mapped to dedicated SDTI port

⁽³⁾ Single trace data line plus trace clock mapped to jtag_emu0, jtag_emu1 pins

The jtag_emu0 debug signal routing is directly defined by the EPM CONTROL[0] setup.

The jtag_emu1 debug signal routing depends on the debug function mapped to jtag_emu1 and the debug signal routed to jtag_emu0.

The etk_clk debug signal routing depends on the debug function mapped to etk_clk and the debug signals routed to jtag_emu0 and jtag_emu1.

The etk_ctl debug signal routing depends on the debug function mapped to etk_ctl and the debug signal routed to jtag_emu0, jtag_emu1, and etk_clk.

If the same debug feature is mapped to consecutive etk_d pins and the debug signal [n] is routed to etk_d[i], the debug signal [n+1] is routed to etk_d[i+1].

If different features are mapped to consecutive etk_d pins and the debug signal [x,n] is routed to etk_d[i], the debug signal [y,0] is routed to etk_d[i+1].

27.4.3.4 EPM Control Access

The EPM control registers are attached to the emulation L4 bus and can be programmed by the debugger through DAP or by the application software. Figure 27-17 shows the two accesses.

Figure 27-17. EPM Control Access

All access done by using DAP are considered debugger access; otherwise, they are considered application access.

27.4.3.5 Claim Procedure

The application or the debugger can own the EPM control registers. The ownership is required to configure or program the EPM. In other words, ownership determines if write access is granted to the component. EPM ownership is exclusive. Hence, simultaneous use of EPM is not permitted. However, the debugger can forcibly seize ownership of the EPM.

Claim state can be read in the [DAPC_EPM2\[31:30\]](#) CLAIMOWNERSHIP bit field. [Table 27-103](#) shows the different claim values returned by this bit field.

Table 27-103. Claim States

State	Value	Definition
Available	00	The EPM has not been claimed.
Claimed	01	The EPM has been claimed.
Enabled	10	The EPM is enabled by the owning party.
Reserved	11	Reserved

If the EPM is in a nonavailable state (the [DAPC_EPM2\[31:30\]](#) CLAIMOWNERSHIP bit field = 01 or 10), the current owner can be read in the [DAPC_EPM2\[28\]](#) CLAIMCURRENTOWNER bit.

To change claim ownership state, write a command in the [DAPC_EPM2\[31:30\]](#) CLAIMOWNERSHIP bit field. [Table 27-104](#) shows the different commands to manage EPM ownership.

Table 27-104. Claim Commands

Encoding	Command	Definition
00	Release ownership	Release EPM ownership. The release command is accepted only from the owner.
01	Claim ownership	Claim access to the EPM. The claim command is successful only if the EPM is available or requested by the debugger and the DEBUGGEROVERRIDE bit is high.
10	Enable unit	Activate the EPM for use. The enable command is accepted only from the owner.
11	No operation	The NOP command does not affect ownership or the claim state.

The debugger can force the claim procedure by writing 1 in the [DAPC_EPM2\[27\]](#) CLAIMDEBUGGEROVERRIDE bit. When this bit is set to 1, the debugger can get EPM ownership even if the application already ownership. When this bit is cleared to 0, the debugger can get EPM ownership only if the current state is Available.

27.4.4 EPM Programming Model

27.4.4.1 EPM Concurrent Debug Examples

[Table 27-105](#) through [Table 27-110](#) show different examples of concurrent debug with the corresponding EPM control field and value.

Table 27-105. Triggers

EMU Pin	Debug Mode	Debug Signal Routing	EPM Control Field	EPM Control Value

Glossary

Numerical

- 2D**— Two dimensional
- 3D**— Three dimensional
- 3GPP**— 3rd Generation Partnership Project

A

- ABS**— Absolute value
- ADC**— Analog-to-digital converter/conversion
- AEW**— Adaptive multirate
- AHB**— Advanced high-performance bus
- AMR**— Adaptive multirate; also Audio modem riser: An Intel specification that defines a new architecture for the design of motherboards.
- APB**— Advanced peripheral bus
- APE**— Applicative processor engine
- API**— Application programming interface; also ARM port interface
- ARAU**— Auxiliary register arithmetic unit
- ARGB**— Alpha, red, green, blue
- ASIC**— Application-specific integrated circuit: A chip built for a specific application. In the context of this document, ASIC refers to the FPGA that resides on the EVM board.
- ASCII**— American standard code for information
- ATR**— Answer to reset
- AVC**— Advanced video coding (MPEG4 - Part 10 also known as H264)
- AXI**— Advanced extensible interface

B

- BB**— Busy bus
- BCD**— Binary-coded decimal: A representation of decimal digits (0–9) using a nibble that uses a certain number of bits. For example, using 4 bits, two BCDs can be packed into 1 byte.
- BGA**— Ball grid array
- BGAPTS**— Band gap voltage and temperature sensor
- BGT**— Block guard time

BIOS— Built-in operating system

BIST— Built-in self-test

Bluetooth®— A short-range radio technology designed to simplify communications among network devices and between devices and the Internet. It also simplifies data synchronization between network devices and other computers.

BPP— Bits per pixel

BTA— Bus turn around

C

CALU— Central arithmetic logic unit

CAVLC— Context-adaptive variable length coder

CAVLD— Context-adaptive variable length decoder

CBUFF— Circular buffer

CDL— Controlled delay line

CE— Chip enable

CH— Configuration header. To use settings other than ROM code defaults, (that is, clock frequencies, SDRAM/DDRAM settings, or GPMC settings).

CID— Card identification number

CIF— Common intermediate format. A video format used in video conferencing systems that easily supports both NTSC and PAL signals. CIF is part of the ITU H.261 video conferencing standard. It specifies a data rate of 30 fps, with each frame containing 288 lines and 352 pixels per line.

CLE— Command latch enable

CLK— Clock

CLUT— Color look-up table

CMOS— Complementary metal oxide semiconductor

CMT— Cellular mobile telephone

Codec— Coder/decoder or compression/decompression: A device that codes in one direction of transmission and decodes in another direction of transmission.

ConnID— Connection identifier: An initiator module identifier. A ConnID transmitted in-band with the request and is used for protection and error logging mechanism.

CP15— Coprocessor 15: This coprocessor controls the operation and configuration of the TI925T.

CPSR— Current program status register

CPU— Central processing unit: The CPU is the portion of the processor involved in arithmetic, shifting, and Boolean logic operations, as well as the generation of data and program memory addresses. The CPU includes the CALU, the multiplier, and the ARAU.

CRC— Cyclic redundancy check

CS— Chip-select

CTRL— Control

CVBS— Composite video broadcast signal

CWT— Command wire tracer

D

D2D— Die-to-die

DAC— Digital-to-analog converter

DBB— Digital baseband

DBI— Display data interface

DCS— Display command set

DCO— Digitally controlled oscillator

DCT— Discrete cosine transform: A fast Fourier transform used to manipulate compressed still and moving picture data.

DDR— Dual data rate

DE— Data enable

DFF— Digital flip-flop

DFT— Design for test

DI— Data identifier

DISPC— Display controller

DLL— Delay-locked loop

DMA— Direct memory access: A mechanism whereby a device other than the host processor contends for and receives mastery of the memory bus so that data transfers can occur independent of the host.

DMC— Data memory controller

DPD, DPDM— Deep power-down mode

DPF— Dynamic power framework

DPI— Display parallel interface. Digital implementation of PLL

DPLL— Digital phase-locked loop

DRD— Dual role device

DRDY— Data ready

DRM— Digital rights management

DSI— Display serial interface

DSP— Digital signal processor: A semiconductor that manipulates discrete or discontinuous electrical impulses in a manner that implements a desired algorithm.

DSS— Display subsystem

DT— Data type

DVFS— Dynamic voltage and frequency scaling

E

EAV— End of active video

- ECC**— Error checking and correction; also error correction code.
- ED**— Endpoint descriptor
- EDC**— Error detection code
- eFuse**— Electrical fuse: A one-time programmable memory location usually set at the factory
- EHCI**— Enhanced host controller interface
- EMC**— External memory controller
- EMI**— Electromagnetic interference
- EMV**— Initial letters of Europay, MasterCard, and VISA, the three companies which originally cooperated to develop the EMV standard
- EOF**— End of frame
- EOT**— End of transfer
- ES**— Erase status
- ETB**— Embedded trace buffer
- ETSI**— European Telecommunications Standard Institute
- ETM**— Embedded trace macrocell

F

- FC**— Frame counter
- FE**— Framing error: An error that occurs when the asynchronous serial port receives a data character that does not have a valid stop-bit.
- FIFO**— First in first out: A queue; a data structure or hardware buffer from which items are removed in the same order they were put in. A FIFO is useful for buffering a stream of data between a sender and receiver which are not synchronized; that is, the sender and receiver are not sending and receiving at exactly the same rate. If the rates differ by too much in one direction for too long, the FIFO becomes either full (blocking the sender) or empty (blocking the receiver).
- FIQ**— Fast interrupt request
- FlatLink™ 3G**— A Texas Instruments display interface protocol
- FS**— Frame synchronization
- FSM**— Finite state-machine: A model of computation consisting of a set of states, a start state, an input alphabet, and a transition function that maps input symbols and current states to a next state.
- FSR**— Fault status register
- FT**— Feed through

G

- GDD**— Generic distributed DMA
- GP device**— General-purpose device
- GPIO**— General-purpose input/output: Pins that can accept input signals and/or send output signals but are not linked to specific uses.
- GPMC**— General-purpose memory controller
- GSM**— Global system for mobile communications

H

- HC**— Host controller
- HDTV**— High-definition television
- HFP**— Horizontal Front Porch
- HNP**— Host Negotiation Protocol
- HPI**— Host port interface
- HS**— High speed
- HSEC**— Horizontal sync end code
- HSSC**— Horizontal sync start code
- HSYNC**— Horizontal synchronization: A bidirectional horizontal timing signal occurring once per line with a pulse width defined as an integral number of FCLK periods. Synchronization signals can be used to enable retrace of the electron beam of a display screen. Also HS.
- HSW**— Horizontal Synchronization Pulse Width
- HVGA**— Half-size video graphics array. One-half the resolution of VGA
- HW, H/W**— Hardware
- HWA**— Hardware accelerators

I

- I²C**— Inter-integrated circuit: A multimaster bus where multiple chips can be connected. Each chip can act as a master by initiating a data transfer.
- I2S**— Inter-IC sound: A digital audio interface standard.
- IA**— Initiator agent, also Identifier address
- IC**— Integrated circuit
- ICR**— Intersystem communication registers
- IF**— Interface
- INT**— Interrupt: A signal sent by hardware or software to a processor requesting attention. An interrupt tells the processor to suspend its current operation, save the current task status, and perform a particular set of instructions. Interrupts communicate with the operating system and prioritize tasks to be performed.
- INTC**— Interrupt controller
- I/O**— Input/output
- IP**— Intellectual property
- IPC**— Interprocessor communication. Also referred to as *mailbox*.
- IrDA**— Infrared Data Association: Represents the group of device manufacturers that developed a standard for transmitting data via infrared light waves.
- IRQ**— Interrupt request: IRQs are hardware lines over which devices can send interrupt signals to the microprocessor.

ISO— Isochronous: This refers to processes where data must be delivered within certain time constraints. For example, multimedia streams require an isochronous transport mechanism to ensure that data is delivered as fast as it is displayed and to ensure that the audio is synchronized with the video. Also, *International Standards Organization*.

ISP— Image sensing product; also image signal processor

ISR— Interrupt service routine: A function or set of functions that are called when an interrupt is encountered.

ITU— International Telecommunications Union

IVA— Image and video accelerator

J

JPEG— Joint Photographics Experts Group

JTAG— Joint Test Action Group: The JTAG was formed in 1985 to develop economical test methodologies for systems designed around complex integrated circuits and assembled with surface-mount technologies. The group drafted a standard that was subsequently adopted by IEEE as IEEE Standard 1149.1-1990, IEEE Standard Test Access Port, and Boundary-Scan Architecture.

K

Kb— Kilobits

KB— Kilobyte, 1024 B

Kbps— Kilobits per second

L

L1— Level 1 cache/memory

L2— Level 2 cache/memory

L3— First level of interconnect in platform

L4— Second level of interconnect in AM/DM37x platform

LCD— Liquid crystal display: A display that uses two sheets of polarizing material with a liquid crystal solution between them.

LCh— Logical DMA channel

LDM— Load multiple

LDO— Low dropout

LH— Local host

LINK— Link layer device

LLP— Low-level protocol

LP— Low power, operation mode for PHY

LPDDR— Low-power, double-data rate (SDRAM)

LPM— Low-power mode

LPP— Lines per panel

LPDDR— Low-power, single-data rate (SDRAM)

- LRC**— Longitudinal redundancy check
- LRU**— Least recently used
- LS**— Level shifter; also low speed
- LSB**— Least-significant bit
- LUT**— Look-up table
- LVDS**— Low-voltage differential signaling

M

- Mailbox**— See *IPC*
- Mb**— Megabit
- Mbps**— Megabits per second
- McBSP**— Multichannel buffered serial port: An enhanced buffered serial port that includes the following standard features: buffered data registers, full duplex communication, and independent clocking and framing for receive and transmit. In addition, the McBSP includes the following enhanced features: internal programmable clock and frame generation, multichannel mode, and general-purpose I/O.
- MCSPi**— Multichannel serial port interface
- MCP**— Multi-chip package
- MCU**— Microcontroller unit (refers to the MPU)
- MDDR**— Mobile double-data-rate SDRAM, dedicated to mobile applications
- MIPI®**— Mobile industry processor interface
- MMC**— Multimedia card
- MMC/SD**— Multimedia card/secure data
- MMU**— Memory management unit: The MMU performs virtual-to-physical address translations, performs access permission checks for access to the system memory, and provides the flexibility and protection required for the OS to manage a shared physical memory space between the two processors.
- MPEG**— Motion Pictures Expert Group: A compression scheme for full-motion video.
- MPEG1**— The first MPEG compression scheme specification
- MPEG4**— The most current MPEG compression scheme specification, intended for very narrow bandwidths.
- MPU**— Microprocessor unit
- MS**— Mobile station
- MSB**— Most-significant bit: The highest order bit in a word. The plural form (MSBs) refers to a specified number of high-order bits, beginning with the highest order bit and counting to the right. For example, the 8 MSBs of a 16-bit value are bits 15 through 8.
- MUX**— Multiplex/multiplexer
- Muxed pin**— A pin is muxed when its pin control register field can be reconfigured by software to change the function associated with the pin.

MuxMode— A 3-bit field of the pin control register field which enables to change the mode. Mode programming is assumed by software and selects a function on the device external interface.

N

N/A— Not applicable

NAK— Not acknowledged

NAND— NAND flash memory that is a high-capacity, low-cost, embedded, permanent data storage solution

NF— Noise filter

NMI— Nonmaskable interrupt: An interrupt that cannot be masked or disabled.

NOP— No operation (DSP/CPU instruction)

NR— Noise reduction

NSC— National Semiconductor Corporation

NTSC— National Television System Committee (television broadcast system)

O

OCM— On-chip memory

OCO— One change only

OCP— Open-core protocol

OCPI— Open-core protocol interface

OEM— Original equipment manufacturer

OGL— Open GL (programming API) enable

OHCI— Open host controller interface: This is an industry standard USB host controller interface.

OMAP— An open software and hardware platform targeted at second- and third-generation cellular phones with multimedia capabilities.

OneNand™ — A memory chip based on NAND architecture integrating SRAM buffers and NOR logic interface. It combines the advanced data storage function of NAND flash with fast read speed function of NOR flash.

OTG— On-the-go (USB 2.0 specification)

P

PBIAS— PMOS bias transistor to provide the bias voltage to extended drain I/Os

PCB— Printed circuit board

PCLK— Pixel clock

PCM— Pulse code modulation: A technique for digitizing speech by sampling the sound waves and converting each sample into a binary number.

PDA— Personal digital assistant

PDE— Personal down enable

PE— Packet end

PF— Packet footer

- PH**— Packet header
- PG**— Protection group
- PGA**— Pin grid array
- PHY**— Physical layer device
- PI**— Packet identifier
- PID**— Protocol identifier: The PID register is used in Windows CE mode only.
- PLD**— Programmable logic device
- PLL**— Phase-locked loop: A closed loop frequency control system whose function is based on the phase-sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).
- PMC**— Program memory controller
- POP**— Package-on-package technology
- PMP**— Power management port
- POR**— Power-on reset
- PPI**— Physical layer protocol interface
- PPS**— Protocol and parameter selection
- PRCM**— Power, reset, and clock management
- PRM**— Power and reset manager
- PS**— Packet start
- PSA**— Parallel signature analyzer
- PT**— Packet type
- PVT**— Process, voltage, and temperature (that is, PVT dispersion)
- PWB**— Printed wiring board
- PWM**— Pulse width modulation
- PWR**— Power

Q

- QCIF**— Quarter common intermediate format: A video conferencing format that specifies data rates of 30 fps, with each frame containing 144 lines and 176 pixels per line. This is one-fourth the resolution of CIF. QCIF support is required by the ITU H.261 video conferencing standard.
- QVGA**— Quarter video graphics array (one-fourth the resolution of VGA).

R

- R**— Read only
- RBL**— Read buffer logic
- RFBI**— Remote frame buffer interface
- RFU**— Reserved for future use
- RGB**— Red, green, blue

- RGBA**— Red, green, blue, alpha
- ROM**— Read only memory: A semiconductor storage element containing permanent data that cannot be changed.
- RST**— Reset
- RT**— Real-time
- RVLC**— Reversible variable length coder
- RVLD**— Reversible variable length decoder
- R/W**— Read/write
- RX**— Receive/receiver

S

- S3220**— Abbreviation of Sonics3220. It refers to the L4 interconnect.
- SAM**— Shared access mode: The mode that allows both the DSP and the host to access host port interface (HPI) memory. In this mode, asynchronous host accesses are synchronized internally, and, in case of conflict, the host has access priority and the DSP waits one cycle.
- SAR**— Save and restore: Hardware context saving for power saving
- SAV**— Start of active video
- SCCB**— Serial camera control interface: 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.
- SCL**— Serial clock: Programmable serial clock used in the I²C interface. Also SCLK.
- SCM**— Scan combiner module; also statistic collection module
- SCP**— Serial configuration port
- SD**— Starting delimiter
- SDA**— Serial data: Serial data bus in the I²C interface.
- SDI**— Serial display interface
- SDIO**— Secure digital input/output
- sDMA**— System direct memory access
- SDR**— Single data rate
- SDRC**— SDRAM controller
- SDRAM**— Synchronous dynamic random access memory
- SDTI**— System debug trace interface
- SDTV**— Standard digital television
- SGX**— Abbreviation for graphic accelerator (GFX in ES1.0)
- SIM**— Subscriber identity module
- SIMD**— Single instruction multiple data
- SILVS**— Scalable low-voltage signaling
- SMS**— SDRAM memory scheduler

- SMX**— Abbreviation of SonicsMX. It refers to the L3 interconnect.
- SNR**— Signal-to-noise ratio
- SOF**— Start of frame
- SOT**— Start of transmission
- SRAM**— Static random access memory. Fast memory that does not require refreshing, as DRAM does. It is more expensive than DRAM, though, and is not available in as high a density as DRAM.
- SRG**— Sample rate generator
- SRP**— Session request protocol
- SRRP**— Session RAM restoration pointer
- SS**— Subsystem
- SSR**— Serial synchronous receiver
- SST**— Serial synchronous transmitter
- ST**— Start timer
- STM**— Synchronous transfer mode; also store multiple
- STN**— Super-Twist Nematic: A technique for improving LCD display screens by twisting light rays.
- SVGA**— Super video graphic adapter
- SW**— Software
- SWI**— Software interrupt

T

- TC**— Traffic controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.
- TCK**— Test clock
- TD**— Transfer descriptor
- TDM**— Time division multiplex/multiplexing: The process by which a single serial bus is shared by multiple devices with each device taking turns to communicate on the bus. The total number of time slots (channels) depends on the number of devices connected. During a time slot, a given device may talk to any combination of devices on the bus.
- TFT**— Thin film transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.
- TLB**— Translation lookaside buffer: A cache that contains entries for virtual-to-physical address translation and access permission checking.
- TLL**— Transceiverless link: This is logic that lets the user connect two USB transceiver interfaces together directly without the use of differential transceivers.
- TM**— Target module: A target module cannot generate read/write requests to the chip interconnects, but it responds to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).
- TOC**— Table of contents
- TRM**— Technical reference manual
- TRX**— USB transceiver: The USB analog driver/receiver.

TTB— Translation table base: It points to the base of a table in physical memory that contains section and page table descriptors.

TWL— Table walking logic

TX— Transmit/transmitter

U

UART— Universal asynchronous receiver/transmitter: Another name for the asynchronous serial port.

UICC— Universal integrated circuit card

ULPM— Ultra-low power mode

ULPI— UTMI+ low pincount interface

ULPS— Ultra-low power state

UMC— United memory controller

UNP— Unpredictable

USAR— Universal synchronous/asynchronous receiver

USART— Universal synchronous/asynchronous receiver/transmitter

USB— Universal serial bus: An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

UTMI— USB 2.0 transceiver macrocell interface

UTMI+— UTMI extension supporting USB host and on-the-go

V

VA— Volt-amps: A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.

VC— Virtual channel

VENC— Video encoder

VESA— Video Electronics Standards Association

VFP— Vertical front porch

VGA— Video graphics array: An industry standard for video cards.

VLC— Variable length decoder

VLD— Variable length coder

VMODE— Bi-level voltage control interface

VPBE— Video processing back end

VSEC— Vertical synchronization end code

VSSC— Vertical synchronization start code

VSYNC, VS— Vertical synchronization: A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode).

W

WBL— Write buffer logic

WC— Word count

WD— Watchdog: A timer that requires the user program or OS periodically write to the count register before the counter underflows.

WDT— Watchdog timer

WLAN— Wireless local area network

WMV— Windows media video

WMA— Windows media audio

Word16— 16-bit word

Word32— 32-bit word

WP— Write protect

WSS— Wide-screen signaling

WWT— Work waiting time

X

XGA, XVGA— Extended graphics array

XIP— Execution in place

Y

YUV— Luminance-Bandwidth-Chrominance

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components which meet ISO/TS16949 requirements, mainly for automotive use. Components which have not been so designated are neither designed nor intended for automotive use; and TI will not be responsible for any failure of such components to meet such requirements.
