Foreword

This Technical Specification (TS) has been produced by the ETSI 3rd Generation Partnership Project (3GPP).

The present document may refer to technical specifications or reports using their 3GPP identities, UMTS identities or GSM identities. These should be interpreted as being references to the corresponding ETSI deliverables.

The cross reference between GSM, UMTS, 3GPP and ETSI identities can be found under www.etsi.org/key .

Contents

Foreword

This Technical Specification has been produced by the 3GPP.

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of this TS, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version x.y.z

where:

- x the first digit:
  - 1 presented to TSG for information;
  - 2 presented to TSG for approval;
  - 3 Indicates TSG approved document under change control.
- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
- z the third digit is incremented when editorial only changes have been incorporated in the specification;

1 Scope

This specification provides a definition of a Wide Area Synchronization protocol. The synchronization protocol is based upon IrMC level 4.

The present document covers Wide Area Network Synchronization between current and future mobile communication end-user devices, desktop applications and server-based information servers. This is a living document and, as such, it will evaluate new technologies (e.g. XML) for inclusion as they become readily available.

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies.
- A non-specific reference to an ETS shall also be taken to refer to later versions published as an EN with the same number.

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

Bluetooth: a technology specification for short range radio links between mobile PCs, mobile phones and other portable devices. (http: //www.bluetooth.com/)

GET: the operation of requesting that the server returns an object from to the client as defined in the IrDA IrOBEX specification

GSM: Global System for Mobile communications

HTTP: HyperText Transfer Protocol

IrDA: an industry consortium set up to define a set of short range Ir communications standards. (http: //www.irda.org/)

Level 1: minimum level support defined in the IrDA IrMC set of specifications

Level 2: access level support defined in the IrDA IrMC set of specifications

Level 3: index level support defined in the IrDA IrMC set of specifications

Level 4: sync level support defined in the IrDA IrMC set of specifications

MIME: Multipurpose Internet Mail Extension

PUT: the operation of sending one object from the client to the server as defined in the IrDA IrOBEX specification

SSL: Secure Socket Layer

Synchronization: the process of exchanging information between multiple physical or virtual locations for the purpose of ensuring that each location's copy of that information reflects the same information content

vCalendar: a format defined by the IMC for electronic calendaring and scheduling exchange with extensions as defined in the IrDA IrMC set of specifications

vCard: a format defined by the IMC for electronic business card exchange with extensions as defined in the IrDA IrMC set of specifications

WAP: an industry consortium set up to define a set of standards to empower mobile users with wireless devices to easily access and interact with information and services. (http: //www.wapforum.com/)

Wide Area Network: a geographically-large range wireless connection between two or more devices for the purpose of transferring information. Large geographical range is typically defined as one kilometer or more in distance

3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

Cookie:	a method of tracking http-based information
IETF	Internet Engineering Task Force
IMC	Internet Mail Consortium
Ir	Infrared
IrDA	Infrared Data Association
IrMC	Ir Mobile Communications
IrOBEX	Ir Object EXchange
OBEX	Object Exchange
PDA	Personal Digital Assistant
PIM	Personal Information Manager
URL:	Universal Resource Location
WAP	Wireless Application Protocol
WML:	Wireless Markup Language
XML:	eXtensible Markup Language

4 Background

4.1 IrMC

The IrMC standard was developed as an extension to the IrDA standard for the purpose of providing an open standard for data exchange between mobile devices or between mobile devices and desktops or PDAs. Among other things,

IrMC defines four levels of support for information exchange. By definition, each higher level must support all of the preceding levels. The four levels are: Level 1 (Minimum Level), Level 2 (Access Level), Level 3 (Index Level), and Level 4 (Sync Level). Level 4 does not require Level 3. Level 2 and Level 4 are the most relevant for synchronization. IrMC has been adopted by IrDA and Bluetooth initiatives and has wide industry support.

4.2 Bluetooth

Bluetooth has adopted the IrMC standard as the basis for their synchronization specification.

4.3 WAP

WAP has not specified a synchronization standard. Attempts to form a work group last year were abandoned.

5 IrMC

There are two approaches regarding syncing of a mobile device. Either the logic of the synchronization has to be controlled by the server or by the mobile device. It has to be decided whether the mobile device should be the client or the server in the synchronization process. As the mobile device has a limited amount of memory and limited processing capacity, it is desired to perform as much of the processing as possible outside of the mobile device. In this case the mobile device becomes the server in the synchronization process, only performing the operations the client tells it to perform. This introduces a problem, as the mobile device is an Internet client, and now has to act like a server. How this is solved is explained in chapter 6.2.

To be able to synchronize a mobile device calendar, a set of rules for how to read and write data from and to the mobile device has to be defined. It must also be decided how to keep track of changes done in the mobile device. An existing, and widely spread, standard for this is IrMC. IrMC provides a model for how to store and access data, such as calendar items, contacts and more. IrMC is usually put in the application layer on top of the OBEX layer in an IR stack. The purpose of this document is to describe how to apply IrMC and OBEX on the Internet, using 3GPP. This requires tunneling of OBEX in 3GPP and reversing the client/server roles.

6 Tunnelling of OBEX

There are two major problems with tunneling OBEX over a wide area network.

The first problem is that no logical connection is kept between the client and the server. In the same way that HTTP is stateless, 3GPP only knows a client at one Request/Response-pair at the time. This means that the state awareness of an application has to be implemented by the application.

The second problem is that the client and the server roles are strictly defined. The client always requests the server and never the other way around. To get around this, a protocol has to be defined that emulates the reversion of the roles.

6.1 Introduction of State

The problem with achieving state awareness on the Internet is usually solved by creating a session object on the server that identifies the client by a cookie. Cookies are not yet a standard of 3GPP and also introduce scalability problems on the server side. The option left is to pass a Session Id between the client and the server throughout the session. This solution is widely adopted on the Internet today.

Usually, when state awareness has to be achieved on the Internet, the client is a browser and the Session Id has to be passed back and forth in hidden fields of forms. As the synchronization of a calendar application in a mobile phone is performed by a program and does not involve a browser and no interactivity with the user, a Session Id only has to be passed to the client at initialization of the synchronization process. The client however has to pass the Session Id in every request to be identified by the server.

The Connection Id used in OBEX is a 4-byte number. The Session Id chosen for the synchronization is a 128-bit (16 bytes) number. Preferably this number should be generated as a GUID (Global Unique Identifier) as these numbers are guarantied to be unique.

6.2 Client/Server

In the case of synchronizing a mobile device with a server's data, it is preferable to put the synchronization logic on the server side, as the mobile device has limited resources of memory and processing capacity. The synchronization process should thus be controlled by the server. The connection however should be initiated by the client. As the Internet Request/Response model contradicts this, we have to define a way to get around this.

The approach is to let the client (the mobile device) consecutively query the server for what operation it wants to perform on the client. The client will then perform the action and query the server for a new task. This is repeated until the server has no more tasks to perform.

The client will always call the server with OBEX headers as http POST data. The reason for using POST is that there is a size limit for sending data in the URL, using the GET method. Using the POST method also avoids problems with special characters, using binary POST (binary POST is not supported in WAP1.1, however. Another solution is provided below). Every client request implies permission for the server to request a client task in its response.

6.3 Binary Post

As binary POST is not supported in WAP1.1, the OBEX headers are base64-encoded and sent as plain text.

This could result in sending 33% more than the ammount of data neccesary.. The solution is however only temporary, awaiting WAP binary POST.

6.4 The secure connection

The authentication process only guaranties that the client and the server can rely on each others identity during the connection process. The connection that is established is not secure and could easily be tapped for information. It is therefore desired to encrypt all data that is sent between the client and the server. 3GPP currently does not guarantee strong enough encryption so we will ensure data is secure and untampered.

In the case of a synchronization of a mobile calendar over 3GPP, there are actually two different transports that has to be considered. First it is the transport from the mobile device to the 3GPP gateway. Then there is the transport from the gateway to the web server. The transport from the mobile device to the gateway is sent over GSM, which is fairly well encrypted. The transport from the gateway to the web server is not protected in any way though. To solve this problem we will use a third party product, e.g. "Wireless Jalda", to establish a protected connection from the gateway to the web server. This should be transparent from the mobile device and set up the required SSL connection.

6.5 Connect

The connect sequence sets up the connection from the mobile device to the web server. The session id has to be assigned in the first response from the server, as more request/response pairs are needed to complete the authentication procedure. The Connect procedure is always invoked by the client.

	Data	Description
Request →	<OBEX push>	The mobile device alerts the web server, sending an empty obex push.
Response ←	<obex connect with authenticate challenge, WAN UUID and target >	The web server responds with a 16 byte session id and the obex headers for connect with authenticate challange. The server also sends an obex target header, indicating calendar synchronization.
Request →	<obex unauthorized with authenticate challenge containg user name in realm, WAN UUID and who header >	The mobile device responds to the connect request by sending an unauthorized response with authernticate challenge, forcing the web server to authenticate itself. Username is sent as realm. Who header with assigned connection id.
Response ←	<obex connect with authenticate challenge and authentication response , and connectionid>	The web server verifies the mobile device and authenticates itself.
Request →	<obex success with authenticate response, WAN UUID and connectionid>	The mobile device verifies the web server and sends an obex success.

Response ←	…	The web server now starts acting like the a client to the mobile device, sending PUT and GET operations to the mobile device.

6.6 Disconnect

Disconnection can either be invoked by the client or be invoked by the server as a last response. The client's session is then destroyed in the server. A third case is that the connection is lost for other reasons, e.g. power failure by the client. In this case, the session should be timed out automatically.

6.6.1 Client disconnection

The client normally should not invoke the disconnection. Should the client however need to disconnect, the following sequence should be used:

	Data	Description
Response ←	…	The web server asks the mobile device to perform some operation.
Request →	<obex disconnect, WAN UUID >	The mobile device send an obex disconnect to the web server.
Response ←	-	The web server destroys the session and responds with an empty response.

6.6.2 Server disconnection

When the server is done synchronizing its content, it should disconnect the client. The following sequence should be used:

	Data	Description
Response ←	<obex disconnect> <obex connectionid>	The web server send an obex disconnect to the mobile device and destroys the session.
	-	The mobile device disconnects and sends no more requests to the web server.

6.7 Put

The PUT operation sends a named vCalendar object from the server to the mobile device. The PUT operation can only be invoked by the web server.

	Data	Description
Response ←	<obex put, connectionid>	The web server sends a put request to the mobile device.
Request →	<obex put response, WAN UUID >	The mobile device performs the put operation and responds with the resulting obex data.

6.8 Get

The GET operation retrieves a named vCalendar object from the mobile device. The GET operation can only be invoked by the web server.

	Data	Description
Response	<obex get> <obex target>	The web server sends a get request to the mobile

←		device.
Request →	<WAN UUID ><obex get response>	The mobile device performs the get operation and responds with the resulting obex data.

6.9 Timeouts

The operation will wait for N seconds before retry. The timeout will be similar to one used on browsers and implementation dependent.

7 Use Case

The user choses “remote sync” and is prompted for the URL, for example www.somesite.com, userid and password. The userid will be sent to the server. The userid and the password will be saved in the local storage of the mobile device.

www.somesite.com
OBEX PUSH

When the WAP server receives this, it will try to establish an OBEX connection with the mobile device, acting as a primary from an OBEX point of view. An OBEX Connect request with a WAN UUID header and an Authentication challenge header will be sent. The WAN UUID header will contain a unique16 byte UUID that will be used to identify this session. The server also sends an obex target header, indicating that a syncronization is in progress.

OBEX Connect With Authenticate
Challenge header + WAN UUID + target

When the phone receives the OBEX connect, it will respond with an OBEX Unauthorized response and an Authenticate Challenge of it’s own.The user id is sent in the realm field in the obex authorize header. From now on, the given UUID must be present when a request is sent from the phone to the WAP server. This is the only way that the server can recognize the phone. The UUID will be identified with the WAN UUID header, which means that the phone identifies itself with the given UUID. The client also assigns a connection id that is sent in an obex who header in every request.

OBEX Unauthorized + WAN UUID header
+ Authenticate Challenge header + Who

Receiving this, the WAP server resends the same command as last time but this time also adds the Authenticate Response header. The server always sends an obex target header, containg the connection id.

OBEX Connect + Authenticate Challenge header +
Authenticate Response header + connectionid

If the OBEX secondary at this stage verifies the received request-digest with the one generated by itself, the client is authenticated and the response will be an OBEX Success with an Authenticate Response header.

OBEX Success + WAN UUID header +
Authenticate Response header

At this stage the OBEX connection is up and the actual synchronization can start. We are now in the middle of a WAP request/response pair and the WAP server response will now contain a OBEX Get command, asking for the mobile's Change Log. The steps following are identical to the ones in a local synchronization from an OBEX and IrMC point of view, the only real difference is the use of the WAN UUID header when sending from the mobile. Worth mentioning is that this form of remoted synchronization is not suited for a slow sync [see reference 2]. The user is supposed to do the first synchronization locally, using for example cable or IR.
